Google

Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

NEW YORK, JANUARY, 1885.

NOTICE.

Subscribers who desire to avail themselves of the clubbing offer in our Prospectus, will please bear in mind that the ELECTRICAL REVIEW *mentioned, is published in New York, while the* LONDON TELEGRAPHIC JOURNAL AND ELECTRICAL REVIEW *is the title of a different periodical.*

ELECTRICAL PROGRESS IN 1884.

IF the year which has just closed has proved a disappointment to many sanguine investors in electrical enterprises, they may reflect that they are not alone in failing to realize their highest anticipations. So far as invention is concerned, however, every failure marks the general progress of the arts; therefore we may safely assume that whatever the record, there must be general advancement.

The year opened with a multiplicity of claimants to a share in the rich harvest which is being gathered by the American Bell Telephone Company. These various movements have had their thousands of sympathizers, their hundreds of supporters, and doubtless their scores of victims. Many were actuated by hope of legitimate gain, others by what they believed to be a sense of justice, while it is not unlikely that a few shrewd minds scented a field for possible plunder. Temporary encouragement was derived, on January 25, from the refusal of Judge McKennan in the United States Circuit Court at Philadelphia, to grant an injunction against the Overland Telephone Co., in view of the near approach of the Bell-Drawbaugh trial in New York city. The decision in the latter case just rendered by Judge Wallace will doubtless cause embarrassment in the procurement of the funds necessary to sustain further speculative enterprises of this character. It is a fair presumption that the removal of all uncertainty as to the future status of the Bell patents will develop renewed activity in the extension of telephone facilities.

The agitation of the question of underground wires has been felt in various parts of the country, and those of our readers who have watched our correspondence may consider themselves tolerably well informed in respect to the actual progress made toward placing electrical wires underground. We regret to be obliged to say that this question has not by any means been fairly treated by the public press, nor have the laws which have been passed evinced any particular disposition on the part of legislators to bring about the desired reform without seriously interfering with various branches of electrical business, which certainly cannot withstand the burden which is about to be forced upon them. Actual progress has been made in placing wires underground in New York, Brooklyn, Chicago, Philadelphia, Pittsburg, Boston and Washington, but it is highly improbable that the requirements of the statutes will be complied with in any of these cities upon the dates fixed by law.

Electric lighting is slowly emerging from the stage of sensational speculation which attended its earlier period of development, and those companies which have survived the ordeal of active competition are gradually building up a substantial legitimate business based upon the merits of their respective systems. The arc lamp has fairly established its reputation as an effective and comparatively cheap method of illumination for large areas, and its use in New York city is very extensive for street lighting, where over 3,700 gas lamps have been displaced by it. Its value for lighthouse purposes is being practically tested by its adoption for use at the recently completed tower on Hallett's Point, Hell Gate channel, the eastern entrance to New York harbor.

The superiority of the incandescent lamp for interior illumination is now admitted, even by those whose interests would naturally lead them to oppose it. For the safe, effective and healthful lighting of vessels, it supplies a want which had never been adequately met. As a competitor of gas on equal terms, for ordinary house-to-house lighting, it has thus far failed to achieve financial success. The most decisive improvement in electric lighting which has been made public during the year is unquestionably the mammoth incandescent lamp invented by Edward Weston, and first shown at the Philadelphia exhibition.

The electrical transmission of power has not as yet been very extensively applied, but its successful future is looked forward to with great confidence by those who are

Digitized by Google

best qualified to judge of its numerous advantages. Should it be substituted for steam on one of the lines of the elevated railways in New York city, there will be little question as to its prompt appearance in various other channels of usefulness.

Although numerous changes have taken place in the relative attitudes toward each other of the "opposition" telegraph companies, in the matter of pooling arrangements, and business partnerships, they now stand in this respect just where they did one year ago. The bankruptcy of the Bankers and Merchants' Telegraph Company has been the ostensible reason for the disruption of the working agreement between them, although the war in rates has doubtless caused a diminution in receipts which has been detrimental to the interests of all. The four rival companies are now being operated independently of each other, a state of affairs which is not likely to continue through another year.

The International Electrical Exhibition at Philadelphia, the first of its kind in America, afforded an opportunity for the convenient examination of the most interesting achievements in the field of electrical science. It was well patronized and proved a financial success, although two weeks' receipts were practically lost by reason of the exhibits not being wholly in readiness until that length of time had elapsed.

The American Electrical Exhibition is now in progress in Boston.

The World's Fair which is now open at New Orleans will also embrace some important electrical features, the starting of the machinery by an electrical impulse at the hand of President Arthur at Washington, 1,200 miles away, being an event which, perhaps, gives a popular idea of electrical power transmission. As a matter of record, however, we must state as a fact, that the steam was turned on by hand, in the ordinary manner, when the signal was received.

Among the deaths of the year was that of Th. Achille-Louis Du Moncel, more familiarly known in electrical circles as Comte Du Moncel. He had been for over 30 years an industrious experimenter and author, his literary work being of an especially popular character. At the date of his death he was the scientific editor of *La Lumière Electrique*, to which he contributed many interesting and important papers.

The eminent English electrician, Robert Sabine, died on the 25th of October. Although not a voluminous writer, his ability was recognized as of a practical and useful character, and he was among the earlier of the authors who have left a lasting impression upon the minds of our oldest American electrical students.

THE DECISION IN THE TELEPHONE CASE.

On the 1st of December Judge Wallace of the United States Circuit Court handed in a decision in the case of the American Bell Telephone Company against the People's Telephone Company in favor of the complainants, thus terminating, at least for the present, the legal proceedings which have been in progress for more than four years, and sustaining the preliminary injunction against the People's Telephone Company which was obtained some two years ago. The interest excited by this important case, especially in electrical circles, has been so great and so wide-spread that we have felt constrained to publish it elsewhere in full, notwithstanding its unusual length. The oral arguments before Judge Wallace occupied nine days. The following eminent counsel took part in the proceedings: J. J. Storrow and Chauncey Smith, of Boston; E. N. Dickerson and Roscoe Conkling, of New York, on behalf of the complainants, and Lysander Hill and Hon. George F. Edmunds on behalf of the defendants. The experts retained by the complainants were Charles R. Cross, of Boston, and Frank L. Pope, of New York, and by the defendants, Park Benjamin, of New York. The witnesses who testified for the complainants were 169 in number and their depositions occupied 2,493 printed octavo pages, besides 1,047 pages of exhibits, while 366 witnesses testified for the defendants, filling 2,476 pages of testimony and 160 pages of exhibits, making 6,456 pages in all, constituting eight large volumes.

Two months ago, after all the arguments on both sides had been closed, and the evidence had been placed in the hands of the Court, we published an article containing a careful review of the basis of the defence—the claim of Daniel Drawbaugh—in the light of the evidence which had been taken on both sides. In this article the opinion was expressed that the testimony, taken as a whole, failed utterly to prove the existence of any operative electrical telephone in the hands of Drawbaugh, prior to the date of the invention of Bell. We also editorially expressed the opinion that the claimant, Drawbaugh, and the multitude of witnesses who testified in his behalf, had failed to make out a case which could by any possibility be sufficient to overthrow the Bell patent, and furthermore that the case, taken as a whole, indicated the existence of one of the most extraordinary and widespread conspiracies for the purpose of destroying a patent which had ever occupied the attention of the court of justice. In making these remarks we simply expressed our views and opinions as to what the decision of the Court would necessarily be, in view of the law, of the evidence, and of previous decisions of the Federal Courts in similar cases. Our course in this matter has been severely criticised by a contemporary, who is apparently deeply interested in the success of the scheme of the People's Telephone Company, apparently upon the ground that it was an attempt made in behalf of the Bell "monopoly" to influence the decision of the Court. Since the opinion of Judge Wallace has been made public the same journal has reiterated the charge, and has more than intimated that a certain coincidence which it pretends to have discovered between the view of the evidence taken by us and that taken by Judge Wallace indicates that by corrupt means we were permitted to learn in advance what the opinion of the Court was to be. It is needless to remark that such a charge is utterly false, and a most unjustifiable attack upon the character of a Judge whose absolute integrity has never before been questioned.

In so far as our published views can be shown to agree with those subsequently put forth by the Court, it should rather be taken as a compliment to ourselves than as a ground for condemning the Court.

We said that the evidence indicated the existence of a conspiracy. It is not difficult to gather from the language

Digitized by Google

of the decision, that the Judge is of much the same opinion. He says: "It is either true that Drawbaugh had long been treading his solitary path of investigation and experiment in poverty and obscurity, and had perfected his work when the inventions of other explorers were in embryo, *or his story is an ingenious fabrication.* And as will hereafter appear, if the defence is a fabrication, many disinterested witnesses have contributed innocently to give it color and strength, but Drawbaugh *has deliberately falsified the facts.*"

"It is impossible, however, to believe that Drawbaugh can be mistaken in the substance of his testimony, and the conclusion cannot be ignored that *either his testimony is true in its essential parts, or his narrative has been manufactured to fit the exigencies of the case.*"

Assuming the story of Drawbaugh to be true and that he had actually completed and publicly operated electric speaking telephones prior to March, 1876, it became absolutely essential to account for the fact that he omitted to apply for a patent and remained silent for years, while others were appropriating the fame and profits of the invention. The only possible explanation—that of extreme poverty—was set up in the defendants' answer and was attempted to be established by Drawbaugh's testimony. After summarizing his own evidence and that of others on this point, the Court reaches the conclusion, from a few plain facts, that "the theory of extreme poverty is unfounded, and *that Drawbaugh is dishonest in putting it forward,*" and proceeds to sum up the whole matter as follows:

> Where a witness falsifies a fact in respect to which he cannot be presumed liable to mistake, courts are bound upon principles of law, morality, and justice to apply the maxim *falsus in uno, falsus in omnibus.* Drawbaugh could not be mistaken in asserting that it was his poverty which prevented him from caveating or patenting his invention. He was not led to the assertion inadvertently. Those with whom he is associated in the defence understood fully, and so did he, that the fact that a professional inventor and patentee did not go to the Patent Office to secure an invention like the telephone for ten years after it had been completed and demonstrated, was almost conclusive against the theory that he had made the invention, and that unless this presumption could be parried no Court would credit his story. The theory of constraining poverty was therefore formulated in the answer, elaborately fortified by witnesses, and testified to by Drawbaugh. It is overthrown by a few plain, indisputable facts, and Drawbaugh's veracity falls with it.

The Court seizes upon the autobiography of Drawbaugh, prepared by him for publication in the *History of Cumberland County,* as a graphic picture of the inventor and of the man. This is quoted in the opinion, but one or two extracts will suffice. He describes himself as follows: "One of the greatest inventive geniouses (*sic*) of this age (so prolific of great men), who has spent the greater portion of an active life conceiving and producing, as a result of the conceptions of an unusually fertile brain, a score of useful machines and devices." After giving a list of his achievements it concludes: "We are proud to own Mr. D. as a citizen of our township, and deem him worthy of a position at the head of the list of our prominent men, and are hapy (*sic*) to accord him that position."

The Court appropriately remarks that "this portrait, drawn by himself, depicts, without the aid of extrinsic evidence, the ignorance and vanity of the man, and the incongruous and fantastic assortment of his inventive projects. It suggests also the character of a charlatan."

We do not think we do the responsible authors of this scheme any injustice when we again characterize it as a gigantic conspiracy. The parties to it commenced operations by deliberately infringing a patent which had proved very profitable to its owners. An action being brought against them they cast about for a defense, and in some way, with the assistance of able, and it would seem not over-scrupulous attorneys, discovered a fitting tool for their purposes in Drawbaugh, and by working upon his vanity and cupidity, persuaded him, though not without manifest reluctance, to come into court and tell a carefully concocted story of his invention of the electric telephone. It is a significant fact that Mrs. Drawbaugh, who might naturally be expected to be the most earnest, persistent and enthusiastic supporter of her husband's claims, if they were just, has not appeared as a witness. We entertain no doubt that many of the witnesses, in fact the majority of them, were honestly mistaken in their testimony and in their dates, but there are others of whom this charitable view cannot be taken. They were all naturally more or less influenced by that local pride which is always so intense in isolated and comparatively unintelligent communities, to make out as good a case as their consciences would permit for one of their own number. This sentiment was evidently worked upon to the utmost by the attorneys for the defense, and their labors were attended with a degree of success not a little surprising.

It is not probable that the projectors of this fraud had the least idea at the beginning that it would ever have to undergo the searching ordeal of a trial in a Federal Court. They doubtless assumed that the owners of the Bell patent, rather than run the risk of having an invention of such enormous pecuniary value thrown open to the world, would be only too willing to compromise the case for a handsome sum. Many rumors have been published from time to time in reference to efforts said to have been made in that direction. It is almost needless to say that such a policy would have been simply suicidal. The moment Drawbaugh was disposed of a swarm of new claimants of the same character would have arisen. The complete overthrow of this precious scheme—for we think there is no possibility of the reversal of this decision by the Supreme Court—will probably leave the American Bell Telephone Company practically undisturbed in the enjoyment of its possessions at least until the expiration of its principal patents.

ELECTRICITY ON THE ELEVATED RAILROADS.

We remember a story of an occurrence which took place once upon a time upon a railroad which had been "reorganized." There was a new superintendent and a new engineer; there was also an old master-carpenter, but he was a relic of the departed administration. One day the new superintendent sent for the old master-carpenter, and said to him: "I have just received a despatch that the bridge at X—— has been burned; I have directed our engineer to complete the plans for a new bridge at the earliest possible moment. The plans ought to be in your hands

Digitized by Google

by to-morrow morning. Have your men ready to go to work the instant you get them, and do not lose a moment in getting the bridge ready for the passage of trains." The old master-carpenter gravely bowed, and withdrew from the presence. The next morning he presented himself at the superintendent's office, and was asked by that functionary whether the plans for the bridge had yet been delivered to him, to which he made answer : "The bridge is all done, sir, and the trains have been running over it since daylight. I haven't seen nothing of the pictur yet."

The condition of affairs in respect to the proposed employment of electricity to operate the elevated railroads in New York city reminds one of this story. We have been informed by the daily press at regularly recurring intervals of the proceedings which have taken place at a series of meetings lately held at the residence of an eminent engineer and patent attorney in this city, and attended by representatives of various inventions for operating railroads by electricity. We have also been informed that it is proposed to "institute a series of experiments" upon the Second Avenue railroad, in which the several competitors are to be allowed to participate, principally at their own expense, on the condition that their inventions are subsequently to be turned over to a "consolidated company," to be formed for the purpose of monopolizing all the electric railroad patents worth having. We are told that the proportion of stock which the competitors are to receive in this consolidated company in payment for their respective interests is to be determined by a "board of arbitrators," composed, as our esteemed contemporary the *Electrical World* expresses it, of "one very eminent non-resident expert, three absolutely inexpert officials, and one pre-eminent expert absent foreigner."

If this remarkably ingenious and original scheme is ever carried forward so far as the point where the board of arbitration decides "without appeal" upon the comparative value of the different inventions, the scientific world will witness an electrical row of unprecedented dimensions ; but we hardly think it will ever get so far as that. Long before this board of eminent *savans* get their "pictur" completed, we shall probably have electric railroads in successful operation in nearly every country in the world. In fact, we already have the Portrush railroad in Ireland, which is as long as the Second Avenue line, and which has been in successful operation, carrying on a regular traffic the same as any other railroad, for a year or more, and moreover, as we are informed, earning a 12 per cent dividend. It is no doubt true that the mechanical and electrical arrangements of the Portrush railroad would be unsuitable, without material modification, for the elevated railroads of New York city, but the results which have been obtained by it prove conclusively the practicability of the system, and what is more important, the possibility of operating it continuously at a profit.

Apparently the only thing that really needs to be done is to place the elevated railroad problem in the hands of some electrical engineer of experience and ability for solution. There is no lack of this class of talent to be had in this country, although we do not find it represented on the "board of arbitration" above spoken of. In our opinion, the managers of the elevated railroads would find no difficulty in negotiating a contract with the United States Electric Lighting Co., the Edison Electric Light Co., or several other corporations or persons that might be mentioned, who are accustomed to deal with such problems, and would undertake to operate the elevated roads with much greater convenience, economy, and safety than is possible under the present system. We do not, in short, think that anything of importance is likely to be accomplished within a reasonable time in any other way.

ARTICLES.

THE CONSTRUCTION OF LINES FOR ELECTRIC CIRCUITS.

BY THOMAS D. LOCKWOOD.

(Continued from page 269, Vol. III.)

It is not therefore advisable with our present knowledge to use compound aerial cables of greater length than 2 miles for telephonic exchange purposes. When cables of any length between 500 feet and 2 miles are employed, if they are of the rubber or kerite insulation, the Foucaut arrangement should be applied in some form ; and finally if cables are to be used for private lines, or for any purposes not connected with telephone exchanges, and where expense is not a factor, the use of the twisted or closely adjacent metallic return is here strenuously advocated, as a much greater length of cable can thus be employed ; induction being practically eliminated ; and retardation being by no means so pronounced as when the other remedies are employed.

JOINTS OR SPLICES.

The method of making joints or splices in gutta-percha covered conducting wires of aerial or sub-aqueous cables is so succintly described in many text-books that it is quite unnecessary to describe it here. For rubber or kerite cables, it is requisite only to strip off the insulation from the required conductor at the ends to be spliced, and to brighten and thoroughly clean the copper, then to make a long and close twist, after the style of an office wire splice, after which the joint should be soldered and made smooth, and finally covered with good kerite tape. There is a very objectionable kind of tape which is now being liberally bought by persons who know nothing of the demands of good construction (company purchasing agents *et al.*), simply because it is cheap ; and which is sold with corresponding liberality, by dealers who do not care to possess the reputation of selling only good articles, because their customers ask for cheap grades. It will someday be found that in electrical construction only the best materials are cheap.

When a conductor in a paraffine cable is to be spliced, it is necessary to cut the lead covering completely back, until it is found that the core is quite free from moisture ; this can easily be ascertained in the following manner : Melt paraffine in any suitable vessel, and heat it to a temperature of at least 260° F. If now the end of the cable when cut back be dipped in the heated paraffine, bubbles will arise, if the cable is damp. If dry, none will appear. Should bubbles appear, the core must be cut back still farther, until they appear no longer. Separate the conductors, and then splice them in the manner indicated in figure 1. By this kind of a splice we are enabled to join a large number of wires, and draw all equally tight. Joints in paraffine cable conductors should not be soldered, as some hot solder will almost certainly drop among the other conductors, and prove injurious to the insulation. Neither should kerite or rubber tape be placed round the

Digitized by Google

joints. The best way of protecting such a splice in this kind of cable, is to draw over one of the divided ends, before the splice is made, a sleeve of braided cotton, which may then be drawn back over the naked wires after the

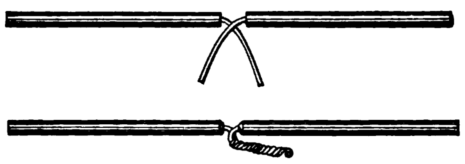

FIGURE 1.

joint is finished. After the conductors are all joined, they may be wrapped together with cotton yarn, twine, or hemp packing, after which paraffine should be heated as before, and poured over the combined splice, until bubbles no longer appear. At the end of a cable, the whole may now be wrapped again with twine. If the joint is made of the entire cable at some intermediate point, the cable must first be opened by carefully cutting round it with a knife or saw, taking care not to cut through. When the lead is nearly cut through, it will easily break.

A sleeve of pipe a little longer than the cable pipe, and long enough to cover the proposed splice, and lap 3 or 4 inches over at each end, should now be slipped over one end, and when the conductors are all joined, and paraffined as we have described, the sleeve can be drawn forward over the splice and joined to the cable pipe by a wipe joint using fine solder.

TERMINAL CONNECTIONS AND LIGHTNING ARRESTERS.

It is very necessary where aerial cables are used, to provide a suitable connection at the outward end for the attachment of the cable conductors to the line wires, and at both ends to attach lightning arresters. We show one very good style of pole box, into which the cable is led intact. The wires are then fanned out to each side and separately terminate at binding screws, which are placed on a bar in a row. The pole line wires enter at each side,

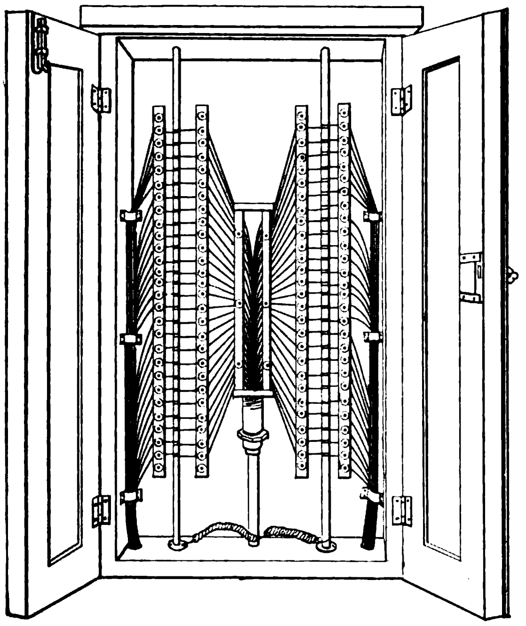

FIGURE 2.

and are terminated in the same way. A metal bar extends on each side between the pole line, and cable line screws, and each pair of terminals is connected by a little piece of comparatively fine wire, which is twisted once round the interposed metal bar. The metal bars being connected with the ground, serve as lightning arresters, and the short pieces are easily renewed.

Where aerial cables run near electric light wires, fusible links, such as narrow strips of tinfoil should, in addition to the lightning arresters, be placed in the line circuit, as electric light currents with a much lower electromotive force than lightning, have great heating power, and would soon destroy a telephone cable.

TESTING INSULATED CONDUCTORS IN CABLES BY MAGNETO BELL.

We have known many persons who were in the habit of testing cable conductors for insulation by ringing a magneto-bell into it, the conductor meanwhile being open at the distant end. As a matter of fact which should be well known, a magneto-generator sending alternating currents will ring its own bell as well on an open as on a closed wire, if the insulation is what it ought to be ; and for this purpose a magneto-bell though almost too handy should not be used. If the insulation is good, the first pulsation sent by the generator may not be sufficient to move the armature, but the second being of opposite direction, having not only to charge the wire but first to neutralize the charge already there, may be strong enough, and the bell rings. On the contrary, if the insulation is not up to the mark, the first charge leaks out before the second comes in and the bell does not ring, except in case the insulation is very low indeed, and then it rings on the escape.

A 50-cell chloride of silver battery, and a magneto-telephone serve to test a cable very well, if the insulation is normally high. Grounding one pole of the battery, we connect the other pole to one of the telephone terminals, and a wire to the other telephone terminal. Now, if we touch the free wire to the end of the cable wire, if the said wire is perfectly insulated, we hear a click, the loudness of which depends on the length of the wire. This click arises from the rush of electricity through the telephone to charge the cable. Now, if the wire be touched a second time no click will be heard because the wire is charged. If the insulation is deteriorating the charge will leak out before the second touch, so that a very perceptible click will be heard the second time. This test, of course, only tells whether the insulation is or is not falling; but if that is once ascertained, the insulation resistance can then be measured. In testing for a break in the same manner, a little experience soon enables one to tell from the sound of the click, the approximate location of the break.

In addition to aerial cables, the constructor is frequently called upon to use office cables. These are usually cables consisting of any required number of wires insulated to a greater or less degree, and covered ordinarily with a cotton braid. If a more ornamental appearance is desired, a silk covering is added. The purpose of these cables is merely a concentration of conductors, so as to economize space, and no special mention of them at this time seems to be required. It will be necessary to refer again, hereafter, to aerial cables when the several methods of suspension will be described.

Before leaving the subject of line wire, it may be mentioned that a line of copper wire built November, 1877, was taken down in August, 1884, and was found to be scarcely diminished in size, and in no way oxidized. This wire was drawn to a degree of hardness which would admit of the regular telegraph twist joint. The line in question was built at Ansonia, Conn., and demonstrates beyond a doubt that hard copper wire (for short lines at all events) will " stand up," that it does not stretch unduly, and that it is not affected in an equal degree with iron, by atmospheric or gaseous agencies.

ELECTRICAL MOTORS AND THEIR CONSTRUCTION.[1]

BY JOHN E. CHASTER.

It is proposed in the present series of articles to give full working drawings and descriptions of an electrical motor, which has been designed with a special view to the production of a machine at once compact and well constructed, and having a high percentage of efficiency

The field magnets constitute the main portion of the machine. The accompanying drawings are made on a scale of half an inch to the inch, or exactly half size, the full size and dimensions being marked on the dimension lines.

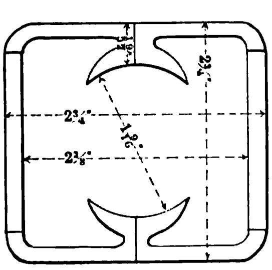

FIGURE 1.

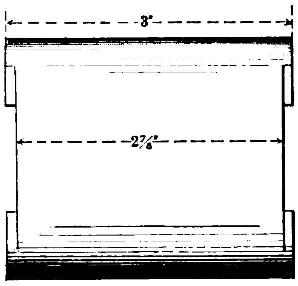

FIGURE 2.

Figure 1 is an end view of the two castings of the field magnets, placed side by side in their proper places, and figure 2 is a side elevation of the same. Figure 3 is an end, and figure 4 a side view of the armature. It is essential that these should be cast from the very best of iron, and thoroughly annealed, so that the character of the metal may approximate as nearly as possible that of wrought iron. Many failures and much loss of electrical energy have resulted from inattention to this important point.

The armature is of the well-known Siemens or **H** form, which is undoubtedly the best ever devised for small motors. Its efficiency is high, while it may be constructed with facility by an amateur of ordinary mechanical skill.

It is preferable to substitute gun metal for brass in the bearings and other non-magnetic portions of the machine, as the use of this material will well repay its slightly increased cost and small amount of additional labor required. The unsatisfactory results which have been attained by amateur constructors of dynamos and motors are largely due to the use of inferior metal.

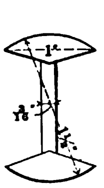

FIGURE 3.

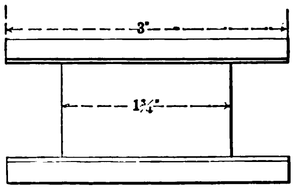

FIGURE 4.

Figure 5 is a front view of the gun metal bearing through which passes the armature shaft or spindle. This is made in two different sizes, which are marked full-size on the drawing. Side views of the same are given in figures 6 and 7. These bearings must be accurately fitted, and care must be taken that they are well trued up, as they must fit square on to the field magnets, as shown in figures 10 and 11. It is not essential that the exact design and shape shown in the drawings should be followed, as this may be varied to suit the fancy of the constructor, providing of course that the mechanical principles shown in the drawing are adhered to and faithfully carried out. Figures 8 and 9 show the gun metal caps which screw on to ends of the armature, into which are screwed the spindles by which the armature is carried. These spindles can be

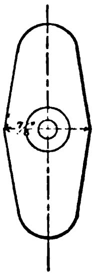

FIGURE 5.

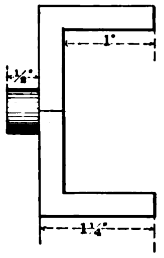

FIGURE 6.

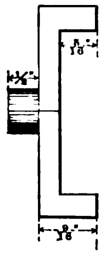

FIGURE 7.

soldered in their places, or secured by pins passing directly through them, to prevent them from unscrewing.

The remark above made, in respect to the precaution of getting everything true, must be borne in mind in every-

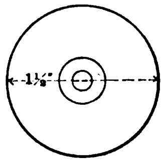

FIG. 8.

FIG. 9.

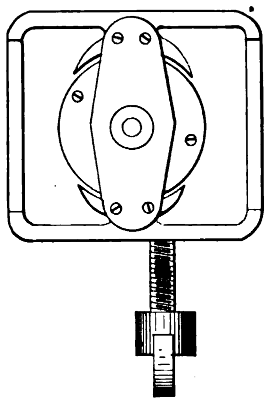

FIGURE 11.

thing relating to the construction of motors and dynamo-electric machines. Such machinery will not allow of any slovenly or slip-shod fitting.

Figure 10 is a cross-section taken through the centre of the armature but not precisely in the centre line of the field magnets, the object being to show in the section the

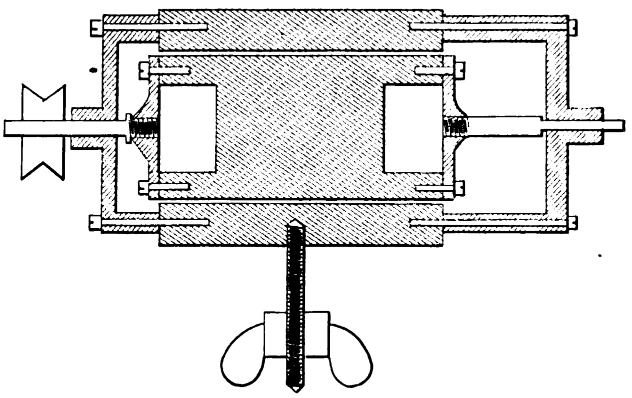

FIGURE 10.

screws by which the bearings are secured to the field magnets. Figure 11 is an end view, in which it will be noticed that the bearings shown in the previous figures 5, 6 and 7 also serve the purpose of binding the outer iron work or field magnets together. A bolt and thumb-nut is shown for securing the machine to a bench or other suitable bed, but if preferred it may be mounted on a polished wooden base.

ELECTRO-CHEMICAL EQUIVALENTS.

BY GEORGE B. PRESCOTT, JR.

According to a recent determination by that careful investigator, Lord Rayleigh (B. A. Rep., 1882), the rate at which silver is deposited under the electrolytic action of a current is 1.118 milligrammes per coulomb of electricity, or, in C. G. S. measure, 1.118×10^{-2}. This value has been generally considered to be more reliable than the old figures of the text-books,[1] and, since later independent experiments by Kohlrausch and Mascart have led to values almost identical, it is now commonly accepted, with confidence that it is at least more nearly correct than any of the figures previously taken.

On the basis of Rayleigh's value for silver I have calculated the electro-chemical equivalents of the other elements usually so tabulated, adding to them potassium and magnesium, metals now reduced by electrolysis.

Although in tables of this nature it has heretofore been customary to employ round numbers to specify atomic weights, I have thought it desirable to base the calculations on the latest accepted atomic weights of the elements as given by Roscoe. In addition to milligrammes per coulomb I have calculated the coulombs per gramme and grammes per ampère hour, all of which figures are given in the following table, including, for the convenience of users, logarithms of the last two named values.

TABLE OF ELECTRO-CHEMICAL EQUIVALENTS, ETC.,

Calculated on the basis of Lord Rayleigh's recent determination of the electro-chemical equivalent of Silver, and the corrected atomic weights of the elements as given by Roscoe.

Elements.	Valency.	Atomic Weight.	Chemical Equivalent. e	Electro-Chemical Equivalent (Milligrammes per Coulomb.) z	Coulombs per Gramme. q	Grammes per Ampère Hour. w	Log. q	Log. w

* Becquerel's extension of Faraday's law showed that the electro-chemical equivalent of an element is proportional to its chemical equivalent. The latter is equal to its combining weight, and not to atomic weight÷valency as defined by Thompson, Hospitalier and others who have copied their tables. For example, the ferric salt is an exception to Thompson's rule, as are sesqui salts in general

Weston Laboratory, Newark, Dec. 13, 1884.

1. Sprague, 1.104; Thompson, 1.134, etc.

THE GROWTH OF TECHNICAL TERMS.

We are moved to refer once more to this subject by the rapid augmentation of words which, because oftentimes backed more by caprice than authority, must inevitably lead to great confusion. Here are a few of these terms of more recent genesis:

The erg.	The watt.	The metric horse power.
The volt.	The henry.	The kilowatt.
The franklin.	The microfarad	The megohm.
The dyne.	The ampère.	The ohm.
The force de cheval.	The centimetre-gramme-second.	

Some of these terms have, by general consent, taken their places as permanent additions to the language of technical science; others are more in the line of test or suggestion. We see in all of this the struggle of a new branch of practical science for definite expression, and as such we welcome these new terms, but "on trial only." Some of them are useless, others barbarous—all of them confusing until brought to the best authoritative definition. The great trouble is that so many of these terms are sprung upon the technical world by self-appointed authorities, who, because their pet words chance to be made use of occasionally by third parties, at once jump at the conclusion that a valuable addition has been made to the language. For instance, it is proposed to call the fellow who runs the electric motor a "motoneer." [Note to the printer: Don't set this up "mutineer."] The next thing, we will have "gasetteer" for the man that runs the gas engine, "keeleteer" for the manipulator of the Keely motor, and "muleteer" for the engineer of the canal boat. Since we are in the midst of a rage for new words, it behooves all good citizens to invent one and then take to tall timber. The fool-killer is on his rounds.—*Iron Trade Review.*

THE MYSTERIES AND MISERIES OF SCIENCE.

An eminent Italian scientist who has been engaged in a new determination of the ohm by absolute measurement, gives in his official report the following harrowing details of the difficulties he has labored under. Some of the discordant results attained by various observers are possibly traceable to causes of this kind hitherto suppressed.

"An other circumstance for me very distressing, is come to influence the rigor of long series of experiences. My laboratory finds itself on the ground floor, in a vast room, very stable and situated at the north; but alongside finds itself the laboratory of chemistry, so that I have the misfortune to have for neighbor, the Prof. Ugo Schiff, who (thing unbelieveable) himself is amused to carry from right and from left long pieces of iron, though he me had promised formally of it to refrain himself.

Now that I have inflicted to M. Schiff, the blame that he merits, in him denouncing publicly, I me propose to explain briefly the manner of which one makes the observations."

MEASUREMENT OF CURRENT STRENGTH WITH A SHUNTED GALVANOMETER.

BY CARL HERING.

The method of measuring currents by means of a shunted mirror galvanometer, or the "shunt method" as it is commonly called, consists essentially of a large, heavy copper wire, having near its ends 2 wires leading to a sensitive mirror galvanometer in series with an adjustable resistance, as shown in figure 1.

The different proportions of the parts are so chosen, that by varying the adjustable resistance any desired strength of currents can be measured with almost the same percentage of accuracy. The shunted galvanometer is calibrated by means of a voltameter, for any convenient steady current, and for a given resistance in circuit with the galvanometer.

Digitized by Google

The resistance of the galvanometer *in series with the shunt* is measured, and from it and the constant obtained by calibration, the various constants for different resistances can be accurately calculated, as will be described later. It is not necessary to determine the proportion of the galvanometer resistance to the shunt resistance, as is commonly supposed, and therefore the multiplication of errors and the error of measuring the small resistance of the shunt, are entirely eliminated, as will be seen below.

The 2 dimensions of the shunt—diameter and length—are calculated from the largest and smallest currents to be measured. The diameter is calculated so that the largest current used will not heat it to such an extent as to cause an error greater than the allowable error, say $\frac{1}{10}$ of 1 per cent. It is preferable, instead of using 1 wire, to use a number of smaller ones parallel, with their ends firmly fastened together with silver solder. The length of the shunt wire is determined by the smallest current and should be such that this current gives a deflection of the needle which can be read to the limit of error allowable, while the adjustable resistance is made zero. For instance,

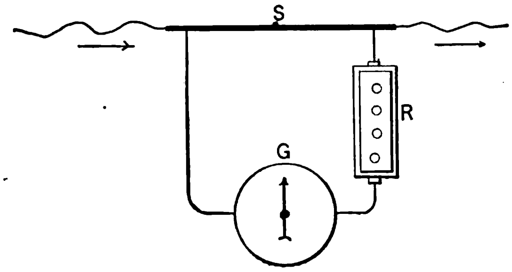

FIGURE 1.

if the allowable error is $\frac{1}{10}$ of 1 per cent., and the scale is in millimeters, the deflection should be at least 10 cm., as any good observer can estimate to $\frac{1}{10}$ of a mm. through a good telescope.

It is very necessary to have a secure contact where the galvanometer wires are fastened to the shunt. They should always be soldered and preferably with silver solder. The shunt wire must be so bent that the large currents in it will neutralize each other as much as possible, so as not to influence the galvanometer needle. It is well to place the shunt so that its plane passes through the plane of the needle. The influence of the current in it upon the needle can then be entirely neglected. Care should be taken that the shunt is well insulated from the ground, and that the effect of the current in the leads on the galvanometer is eliminated.

The galvanometer should be of comparatively low resistance, so that the adjustable resistance forms a large part of the total resistance of the galvanometer circuit, thus allowing for a large range of currents. It is, of course, very desirable to have the needle well dampened, so that the resistance will not have time to heat enough to cause error. The most convenient and accurate method of reading is with telescope and scale, as the cross hairs in the telescope admit of very accurate reading, and it is independent of the lamp used in the ordinary Thomson method. The distance from the scale to the mirror should be as great as possible so as to admit of using a large reading without causing an error. It may easily be calculated what the maximum deflection can be for a given distance of scale, so that the error of proportionality between current strength in galvanometer and reading of scale, is inside of a certain limit. Limiting the error to less than $\frac{1}{10}$ of 1 per cent., the deflection should not be more than 10 to 15 c m. for a distance of scale of about 2 meters. This makes the maximum deflection of needle about $1\frac{1}{2}$ degrees.

To eliminate the effect of a change of the earth's magnetism or any other magnetic change, it is necessary to put a commutator into the galvanometer circuit, and to take readings to the right and left, taking half their difference. This commutator and the leading wires should be carefully insulated from the ground.

For the adjustable resistance, an ordinary plug resistance box can be used. It is not necessary that the absolute resistances be known, as all the resistances of that circuit may be measured in terms of those in the box. It is necessary, however, to know their relative values. If this resistance is of copper, the effect of temperature of the room is entirely eliminated, because the resistance of the shunt and galvanometer circuit are changed in the same proportion; but if it is of german silver, the relative resistances of the shunt and galvanometer circuit will change for different temperatures of the room, necessitating a correction of the constant, as will be shown later.

The calibration is made by means of a voltameter in the main circuit, as shown in the sketch (figure 2) in which G is the galvanometer, R the resistance, C the commutator, S the shunt, V the voltameter and B the battery.

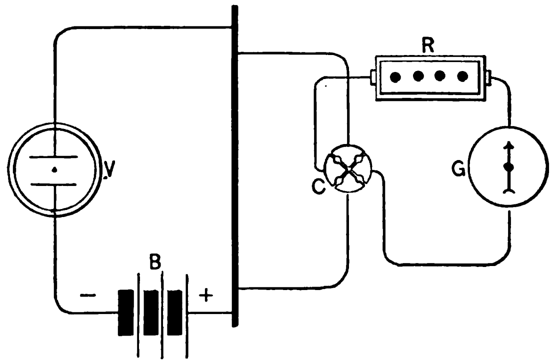

FIGURE 2.

The copper voltameter is generally used on account of its simplicity and the nature of the deposit, which, if proper precautions are taken, will always be a smooth, hard and firm one. The solution of copper sulphate should be as pure as possible, and about 3 parts saturated solution and 2 parts distilled water. It should be well stirred before using it. In using a fresh solution it is better to pass the current through it for 10 to 15 minutes before the calibration, as the first deposit is often imperfect. The anode should be of moderately pure copper, best obtained by electrolysis. The negative plate should be of platinum and not of copper; it should be accurately weighed before each calibration, as it is found that the weight decreases slightly by dissolving the copper deposits of the previous calibration or some other cause. The current strength used to obtain a good deposit is about .15 to .2 ampères for each square inch of single surface, or .3 to .4 ampères for double surface, when 2 copper anodes are used, 1 on each side of the platinum plate. The plate should be well washed with distilled water immediately after the calibration, and dried between filter paper, not over the gas jet.[1] The battery should be as constant as possible and should be put on closed circuit for a while before the calibration. Secondary batteries of low resistance are decidedly preferable. In case the batteries are not constant it is well to put into the main circuit an adjustable low resistance to keep the current constant.

The determinations of the electro-chemical equivalent by Kohlrausch and Rayleigh agree so very closely that their allowable error is entirely within the limits of ordinary practice.

1. It is better to have the platinum or negative plate larger than the copper anode, as it helps to diminish the tendency of the formation of a "beard" on the edges of the platinum plate. From ⅛ inch to 1 inch or even more, on all 3 sides has been found to answer very well, for a plate of 10-20 square inches.

Taking 19.686 mg. of copper per minute and per ampère (Kohlrausch, 1884), and letting

W = weight of copper deposited in milligrams,
D = average deflection during the calibration,
T = time in minutes,
C = current strength in ampères,
K = the constant required, that is, the number of ampères per unit of scale.

Then
$$C = \frac{W}{T \times 19.686}$$
and
$$K = \frac{C}{D} = \frac{W}{D\,T\,19.686}$$

This is the value for the resistance R in the resistance box used during the calibration. The constants for different resistances are calculated from the following formula:

$$K_1 = K\frac{R_1 + G + S}{R + G + S},$$

in which R_1 = the other resistance and $G + S$ the resistance of shunt and galvanometer *in series*. G includes the resistance of leads and commutator. From this equation it is easily seen how very little the resistance of the shunt affects the calculated constants; being in both numerator and denominator of the fraction its value is generally beyond the third decimal place, so that it almost disappears in the equation.

To prove this formula, let

C = the current strength in main circuit,
a and b = the currents in shunt and galvanometer respectively, for a resistance R,
a_1 and b_1 = same for R_1,
The other letters are the same as above.

As the resistance of the shunt is such a very small part of the whole circuit, a change in the resistance of a circuit parallel to the shunt does not change the current appreciably, therefore

$$C = a + b = a_1 + b_1.$$

For the same current

$$\frac{K}{K_1} = \frac{b_1}{b},$$

and
$$\frac{b}{a} = \frac{S}{G + R} \text{ and } \frac{b_1}{a_1} = \frac{S}{G + R_1}.$$

Combining these equations and eliminating the values of a, b, a_1, b_1 and c gives

$$\frac{K}{K^1} = \frac{R + G + S}{R_1 + G + S},$$

or
$$K_1 = K\frac{R_1 + G + S}{R + G + S}.$$

The easiest way to measure the resistance of G + S in terms of the resistances of the box, is to take the deflections for 2 resistances R and R_1 alternately and for the same current. These deflections will then be inversely as the constants, the current being the same. Substituting in the above equation the deflections D and D_1 gives

$$\frac{K}{K_1} = \frac{D_1}{D} = \frac{R + G + S}{R_1 + G + S},$$

or
$$G + S = \frac{D\,R - D_1 R_1}{D_1 - D}.$$

This will be the same for any 2 resistances, but the best conditions are evidently when R and R_1 are near to the value of G.

When the adjustable resistance is of copper there is no temperature reduction necessary, as explained above. For german silver, the correction is as follows, for centigrade degrees:

$$\frac{k}{K} = 1 + \frac{r}{R + G + S}\,.00331\,(T - t).$$

Large letters represent the values for the high temperature and small ones for the low temperature.[2]

To demonstrate this, let

m = temperature coefficient for copper,
n = temperature coefficient for german silver,
Other letters the same as above, capitals for high and small for low temperatures.

$$C = a + b = A + B;$$

$$\frac{a}{b} = \frac{r + g}{s} \text{ and } \frac{A}{B} = \frac{R + G}{S};$$

$$\frac{k}{K} = \frac{B}{b}.$$

Eliminating A and a from first two equations, gives

$$b = \frac{C\,S}{r + g + s} \text{ and } B = \frac{C\,S}{R + G + S}.$$

Combining with third equation

$$\frac{k}{K} = \frac{S\,(r + g + s)}{s\,(R + G + S)}.$$

Substituting for $S = s\,[1 + m\,(T - t)]$
and for
$$R + G + S = r\,[1 + (T - t)\,n] + (g + s)\,[1 + (T - t)\,m]$$
and dividing, gives the desired formula, in which the values of m = .0037 and n = .00039 are substituted. This correction, though small, is very necessary for accurate measurements.

This method is essentially the same that was used at the tests of the Munich, Vienna and Philadelphia electrical exhibitions, where it proved to be an excellent one, especially on account of its convenience and sensitiveness.

In the tests made at the Philadelphia exhibition, 2 shunts were used with the same galvanometer; the first for currents from a fraction of an ampère to 50, and the second from 50 to 300. The first was made of 2 parallel No. 0 naked copper wires, each 4 meters long. The second had 10 parallel wires of the same diameter and $0^{m}381$ long, securely fastened at their ends in a brass casting into which the galvanometer wires were soldered. Neither of the shunts heated perceptibly with the currents for which they were used.

The resistances were an Elliott box of german silver from 1 to 50 ohms. The resistances of the galvanometer and shunt were measured by the method above mentioned, for many different resistances and were found to agree very well, giving as an average about 1.4 ohms.

The calibrations lasted from 20 to 40 minutes, reading every half minute. They were repeated for various resistances, current strengths and temperatures, and when reduced to like conditions agreed very well, notwithstanding the unfavorable circumstances at the test house.

The method can be made direct reading by making the adjustable resistance of copper, so that the constants are reduced each time by ½ or some other amount, and by dividing the scale into ampères for the resistance zero in the resistance box.

2. The calculations are very much simplified by calculating the constants for two extreme temperatures and interpolating for intermediate temperatures, taking the correction proportional to the number of degrees. This is accurate enough for almost all purposes.

STORAGE BATTERIES.[1]

The importance and desirability of an efficient and economical storage battery have been very widely recognized, but it is at the present time pretty generally felt that no existing form of storage battery is perfect, and that they are on the whole extravagant and wasteful to an extent sufficient to more than compensate for their undeniable convenience. It is perfectly certain that their employment has not become at all general, and that they have failed to realize the somewhat sanguine hopes of their early promoters.

It seems worth while to examine into the causes of this partial failure, and to inquire how far the evil opinion held by many practical men concerning our present method of storing electrical energy is justifiable.

One of the main objections is that storage involves a loss of some 50 per cent. of the whole. Now all methods of storing and transmitting energy involves some loss. To say that any particular method involves a loss of 50 or even 90 per cent. is not to condemn it utterly. There are many cases when the convenience of storage outweighs the evil of waste altogether; three principal ones may be specified.

(1.) When the power of the source would be otherwise so completely wasted that every fraction of it stored is clear gain. This is the case of much terrestrial water power. The energy of the tides or of Niagara is enormous, and wholly wasted so far as human activity is concerned; if 50 or even 10 per cent. could be stored in such a way as to be conveniently available, it would be of considerable value, and any arrangement capable of effecting this storage could only with injustice be stigmatized as wasteful. The solar energy of the carboniferous epoch has most of it been wasted; but a small fraction—probably not a millionth per cent.—has been saved and stored in the coal-measures. It is possible to abuse the coal for not having stored more, but we find it a useful modicum nevertheless.

(2.) A second case when the advantage of storage overbalances the loss is when regularity and continuity of supply is needed, and when the source is irregular and fitful. Wind and wave power illustrate this kind of source; it is manifest that wind power has not been so largely used as it would have been, had it been steady and dependable. A practicable method of storing up its energy and giving it out as wanted would gradually cause it to be very largely employed. This case is also illustrated faintly by a gas-engine or jerky motor of any kind, and the regularity and dependableness of a storage cistern may very well make it desirable to put up with some waste provided it be not excessive. Mechanical devices for approximating to regularity, such as the use of slack driving belts, undoubtedly give rise to a waste of power, and so does any form of regulator. But in the utilization of artificial forms of power like this, questions of economy become almost pre-eminent; and wastefulness is here a most serious objection, and, it may be, prohibitive defect. At the same time, if the engine is liable to stop, or if it is not always working, some mode of storing energy may be absolutely necessary, whether wasteful or not.

(3.) Another case, and to some extent the converse of the last, is when the available source is weak, though continuous, while the power is only needed for a short time, but during that time is required to be great. This is exemplified in the operation of pile-driving, where energy is stored in the slowly-raised weight to be suddenly expended on the head of the pile, also in the operation of drawing a bow; or again when a small waterfall or steam-engine, running continuously, is to be utilized for lighting during 5 or 6 hours each day; the obviously right plan in such circumstances as these is to store the energy during the hours it is not wanted, and thus virtually to double or treble the power of the source while it is actually in use.

1. O. J. L. in *Nature*.

Unless, however, the loss occasioned by storage were reasonably small, there would be but small gain in attempting the process in this third case.

It is plainly advantageous to devise a method of storing that shall give out the greater part of what is put in; but we see by these examples that a reasonable loss may be more than compensated by convenience, regularity, availability, and dependableness. Again, when energy has to be transmitted over great distances, it is in practice difficult or impossible to make the expenditure of energy at one end depend upon and be regulated by its consumption at the other; and so, without some system of storage, great waste will ensue during intervals of small consumption. Looking to the immense development which the transmission of energy may be expected to undergo in the course of the next few decades, a convenient and manageable method of receiving large quantities of transmitted energy, and of holding it in readiness until wanted, must be of prime importance.

It was in view of such applications as these that the invention of the storage battery by Faure was hailed with enthusiasm by the highest scientific authority in Great Britain; while the public, jumping to the conclusion that a thing for which so many uses could be instantly found must needs be a profitable investment, hastened to provide money, not for commencing careful experiments and perfecting the arrangement, which would have been wise, but for manufacturing tons of apparatus in its first crude, immature, and untried form. Some day it may perhaps be recognized that because it can be shown that a thing will be extremely useful when perfect it does not follow that it has already attained that perfection, that indeed probabilities based on historical developments are enormously against such abnormal and instantaneous maturity, and that the careful nursing and rearing necessary to healthy maturity are better given in the seclusion of laboratory and study than in the excited and heated atmosphere of the Stock Exchange. It is doubtless recognized already that all preliminary operations are better conducted on a scale smaller than the wholesale manufacturing one. In developing a new industry there are scientific difficulties to be overcome, and there are manufacturing difficulties. By scientific difficulties we mean such as the determination of weak points, the best ways of strengthening them, and generally the discovery of theoretically the best modes of effecting the object in view: manufacturing difficulties begin with questions of expediency and economy—how most cheaply and satisfactorily to carry out the indications of theory, to obtain this or that material—and include the organization of a system of manufacture, of division of labor, of machine tools, which shall enable the work to be done with economy, security and despatch. Over-haste in the preliminary stages causes both these sets of difficulties to be tackled together, and so throws a grievous burden on both adviser and manager. All these untoward conditions have storage batteries experienced; and to say they have not fulfilled the hopes of their early promoters is no more than to say that those hopes were untimely and unreasonable. The period of maturity has been undoubtedly delayed by injudicious treatment, but its ultimate attainment seems to us inevitable; and it is at present a matter of opinion how nearly it has already been reached: certainly great steps towards it have been made. Let us inquire what some of the difficulties encountered have been, and it will be seen that, formidable as some of them are, they belong essentially to an infantile stage, and are not suggestive of constitutional debility.

The first form of manufacture consisted in rolling up sheets of lead and composition, with trousering to keep them separate. The difficulties found were that the coatings would not adhere, but became detached in large flakes; that the trousering got corroded through and permitted short circuiting: and that free circulation of fluid being impossible, the acid became exhausted in some

Digitized by Google

places and concentrated at others, and thus every sort of irregularity began. Now regularity or uniformity is of the most vital and fundamental importance in any form of battery. If any part of a plate is inactive, that part is better away; if any plate in a cell is inactive, it is better away; and if any cells of a battery are inactive, they are infinitely better away. The rolling or coiling up of the sheets being found awkward in practice and liable to detach the coatings, flat plates came to be used, then perforated plates, and then cast grids; these last having such large hole space, that they held enough composition, and held it securely enough, to enable the trousering or intermediate porous material to be dispensed with. This was an evident step in advance: free circulation of the liquid became possible, and could be assisted by stirring; there was nothing to corrode except the plates themselves, and the composition, being in the cells or holes of the grid, might be reasonably expected to adhere. So far expectation was not altogether belied. The adhesion was not perfect, it was true, and pieces of composition sometimes fell out of the holes, especially if too powerful currents were passed through the cell, but still it was much better than it had been; and if the plates were well filled, properly formed, and fairly treated, the composition adhered extremely well and securely. The circulation of the liquid was not automatically perfect either, but mechanical agitation could be readily applied; without it the acid near the bottom of the cells tended to become more concentrated than that near the top, not by reason of gravitation undoing diffusion, which is impossible, but because during each charging fresh acid is formed, and in great part falls to the bottom in visible streams. Another great advantage was that some amount of inspection of the plates became possible, and experience as to the actual behavior and appearance of the plates, began to be accumulated. And painfully varied that experience was. Every variety of extraordinary behavior which could be suggested as probable, and a good many which no one could possibly have imagined beforehand, made their appearance. The hundreds of tons of batteries made at this period doubtless enabled these unpleasant experiences to be more rapidly acquired than would have been done on a small scale, but it was a costly series of experiments. However, the experiments were made, the public involuntarily assisted in the acquisition of experience, and, caring less for knowledge than for marketable commodities, they expressed dissatisfaction at the result. Many of these incipient difficulties are now overcome by the manufacturers, but the great dislike of the public to involuntary experiments, and the shock which their confidence underwent on being unexpectedly called upon to participate in research, have not yet altogether abated.

The main difficulty now experienced was how to keep the plates from touching. They might be put in wooden frames, or elastic bands might be stretched round each of them, and if they would only keep flat it was impossible they should touch unless the composition should drop out of the holes. Sometimes the composition did drop out of a hole, and bridge across the interval between 2 plates, but the more common and more fatal experience was that the plates would not keep straight. In a few months the positives were found to swell, and as they swelled to buckle—to buckle and twist into every variety of form, so that elastic bands, wooden frames, and every other contrivance failed altogether to prevent short-circuiting. The cause of the buckling is of course irregular and one-sided swelling, and the cause of the swelling is apparently the gradual peroxidation and sulphating of the material of the bars of the lead grid, which occupy less room as metallic lead than as oxide or salt. As the bars swell, they press on the inclosed composition, occasionally driving it out, but more frequently, and with properly made and treated plates universally, distending themselves and stretching the whole medial portion of the plate. The edge or frame of the grid is stronger than the middle bars, and is not so easily stretched; in a good and uniformly worked plate it does stretch, and an old positive plate is some quarter of an inch bigger every way than a new one, but if one face of the plate is a trifle more active than the other, it is very plain that the most active side will tend to become convex: and buckling once begun very easily goes on. To cure it 2 opposite plans have been tried: 1 is to leave the plates as free and unconstrained as possible, hanging free it may be from 2 points, thin, and with crinkled or crimped margins to allow for expansion; the other is to make them thick and strong, with plentiful ribs for stiffness, and besides to clamp them up one to another as tightly as may be, and thus in mechanical ways to resist buckling and distortion. I do not know that any one could say for certain beforehand which of these 2 plans would be likely to answer best, but practice is beginning to reply in favor of the latter, and well braced plates of fair thickness show no unmanageable tendency to buckle. It must be remembered that no material can buckle with a force greater than that necessary to restore it to flatness, and this force in the case of lead is very moderate. Hence it may be fairly hoped to overcome and restrain all exuberances by suitable clamps and guides arranged so as to permit flat and even growth, but to check all lateral warpings and excrescences.

Uniformity of action is still essential, especially if all the plates in a cell are clamped together. Plates mechanically treated alike ought to be electrically so treated also, and it is impossible to keep a set of plates working satisfactorily together unless the contact of each is thoroughly and equally good, so that each may receive its fair share of current. Defects of contact have been a fruitful source of break-down and irregularity. Clamps and screws of every variety have been tried, but the insidious corroding action of nascent oxygen exerted through the film of acid which by spray and creeping forms and concentrates on the lugs—this corroding action crawls between the clamped surfaces, gradually destroys all perfect contact, and sometimes produces almost complete insulation. Contacts on the negative plates give but little trouble; contacts on the positives have taxed a great amount of patience. Lead contacts "burned," *i. e.* melted, not soldered on, are evidently less liable to corrosion than brass or copper fittings, or than any form of clamp, but they are apt to be somewhat clumsy if of sufficient conductivity, and moreover they are awkward to undo again, and somewhat troublesome to do. However they have proved themselves so decidedly the best that now no other contacts will be used, and their re-introduction has been followed by a marked improvement in the behavior of the cells. So long as contact with one plate was better than with another, a thing quite possible to happen without any difference being perceptible to the eye, so long was it possible for 1 or 2 plates to remain almost wholly inactive while another 1 or 2 received far more than their share of current, and became distended, warped, overcharged, and ultimately crumbled away. If 1 or 2 plates in a cell are black, and giving off torrents of gas, while the rest are brown and idle-looking, it is pretty fair evidence of irregular and insufficient contact, or else of some great discrepancy in the age or make of the plates. This point also is one that was not attended to in the early stages of manufacture; plates were made for stock, and cells were made up with plates of all ages selected at random from the store. Directly uniformity is perceived to be essential, this is recognized as obviously bad. Plates intended to work together should be of the same age and make, and inasmuch as keeping does not improve them, the best plan is not to make for stock, but to keep material ready, and then quickly make up as wanted. Plates in work deteriorate slowly, but they are wearing out in the fulfilment of their proper function; plates in idleness deteriorate as quickly, and they are rusting out in fulfillment of no function at all.

Digitized by Google

Worn-out plates, however, are by no means valueless. Lead material has a well recognized price, and if attention were given to the subject, it is probable that decrepit and useless plates might be made to yield a very large percentage, if not the whole, of their original lead. For it must be remembered that plates deteriorate not by waste but by accretion: an old plate contains as much lead as a new one, but it contains it with the addition of oxygen and sulphion; no longer a tenacious coherent frame, but a crumbling mass of incoherent powder.

The age of plates is a point of vital interest, though but little is known as to the possibilities in this direction at present. A year may be regarded as a fair average age at the present time; but this is a low rather than a high estimate. Thick plates are found to last far longer than thin, which is only natural when it is remembered that the wearing out is due to corrosion, that corrosion proceeds mainly from the surface inwards, and that the internal portions of a thick plate are to a great extent protected by the mass of superincumbent material. If it can be shown, as we understand it can, (1) that the cost of materials is far more than the cost of manufacture; (2) that the worn-out material has a market value not incomparably less than the original; and (3) that the frequency with which plates have to be renewed is not such as to cause much inconvenience; then we hold that the first stage of the durability difficulty has been overcome. Much more may be hoped for in this direction as experience increases, and it is not extravagant to hope that a well-ribbed, properly-clamped, and fairly-treated thick plate may last as long as five years before it becomes disintegrated.

It is evident, however, that in a region where pure experiment is pre-eminent, and where the units of time are months and years, instead of hours and days, the accumulation of experience is a slow and tedious process. It is no use making statements involving periods of five years when no one has had the present improved form in use for so much as 6 months. Nevertheless it is possible to see that the present cells are better than their predecessors; and as their predecessors have lasted in good condition for a year and more it is not presumptuous to indulge in well-founded hopes. Many of the difficulties connected with the early forms of battery were aggravated by Utopian notions concerning internal resistance and compactness. The internal resistance of a cell was so beautifully small, that the manufacturers were tempted to diminish it still further by putting the plates far too close together. An eighth or tenth of an inch interval is well enough if the plates had been hard rigid slabs of perfect flatness; but it was madness to pack flexible lead plates full of composition certain to swell and liable to drop out so near together as this. Security and dependableness were sacrificed to a natural desire for sudden and Utopian perfection. We may hope that these lessons have been profited by, and that the manufacturers perceive that confidence and security are the first conditions of success, and that minutiæ as to the number of noughts before the significant figures in the specification of resistance begin, though those also are of importance in their turn, are yet of quite secondary consideration. Moreover, this packing of the plates so closely did not really do much to secure the result desired; the greater part of the resistance of half run-down cells is not in the liquid between the plates, but in the surface or scum separating each plate, and especially each negative plate, from the liquid, and hence putting the plates a safe distance, say a quarter or one-third of an inch apart, exerts an effect on the total resistance which is certainly far more than compensated by the ready opportunity thus afforded for access by both sight and touch. The old opaque boxes chock full of plates, with slight india-rubber bands between them, were started and left to Providence. No one could see what went on, nor could one readily get at anything to rectify what was wrong. In the present glass boxes properly arranged on accessible shelves with only plugs or studs between the plates, clear vision through the cell in any direction is easy, and accidental obstruction not only very seldom occurs but if it does it can without difficulty be seen and removed. But it must be granted that these boxes are less compact than their predecessors, and for some purposes, such as locomotion, compactness is of the first importance. Most true, for some purposes. It is not to be supposed that one type of cell will answer every possible demand. A dynamo to be highly efficient must have a large and massive field magnet, but in some places bulk and weight are fatal objections; and in these places smaller and more compact dynamos may be more suitable: something, however, must be given up to secure the required lightness and compactness, some sort of compromise must be effected. Just so with cells: we can point out what is theoretically the best form, and this form may, for large stationary electric light or power installation, be actually the most suitable; but we may also see that for boats, for tramcars, and for fish torpedoes, some very different and far more compact form may be quite essential.

Efficiency, Durability, Economy, Compactness: it may not be possible to attain all these at once—if it were, there would be small room for discussion—but sometimes one and sometimes another will be the pressing necessity, and manufacturers of storage batteries, like manufacturers of dynamos, must be prepared with forms suited to various needs.

We have spoken mainly of difficulties connected with the positive plates, and have said nothing concerning the negatives. It is not that these are not susceptible of improvement, but their faults have been of a less imperious and obtrusive nature. They are not perfect, but they do fairly well, and there has been little need to worry much about them, until the extraordinary behavior of positives had been taken in hand and checked. The time is coming to attend to these also. They fail not from exuberance, but from inertness. As they grow old, they do not swell, and warp, and burst, and crumble, like the positives, but they grow quietly hoary, and serenely decay. The composition in a worn-out negative consists of white sulphate through and through, but the frame remains intact, and it consequently never falls to pieces, nor does it swell. Impurities in the acid used tell upon a negative plate—nitric acid is fatal. Acid much too weak or very much too strong is also deleterious, and idleness is bad. The difficulties connected with negatives mostly depend on their aggravating property of always requiring a quite opposite treatment to positives. The less a positive is formed and overcharged the better. A negative delights in complete formation and frequent overcharge. In recognition of this it is now customary to form them separately, and to give the negative a thorough dose of hydrogen without commencing the corrosion of the positive by an overdose of oxygen. When the discharge from a cell begins to flag, it is the resisting scum of sulphate that has formed over the negative plate which is responsible for the flagging. The true E. M. F. of a cell is wonderfully constant throughout the whole discharge; but the internal resistance is all the time increasing, at first very slowly, ultimately, towards the end, with a rush. One such run-down cell in the midst of a lot of others therefore obstructs the current terribly. If only a series of cells could with certainty be made to work together uniformly, if a series could behave as well as some of the cells in it, no one would have cause to complain.

Through the whole history of the manufacture, from the very beginning, a few cells here and there have always exhibited astonishing efficiency;—the aim of manufacturers may be said to be to bring all cells up to the level of a few. Much progress in this direction has been made, and it may be very fairly expected that, as uniformity is gradually attained, a series of cells subjected to the same treatment

Digitized by Google

may behave in the same manner. Whenever this is certainly accomplished, there will have been reached a high stage of efficiency, beyond which further progress need be only in the improvement of comparably insignificant minutiæ.

The subject of the electrical storage of energy is really one of national importance;—it is comparatively a small matter whether this or that form of storage, or this or that company of manufacturers, succeeds in bringing out the permanent form. It sometimes unfortunately happens that enterprising pioneers only clear the way, and retire just in time for other men to come in and reap the fruits of their labors. So much capital and so much labor have been already expended in the effort to bring storage batteries to perfection, so great progress has been made, and so apparently small are the steps which yet remain to be accomplished, that we may surely fairly hope that some of the original believers in their great, and as it seems to us inevitable, future may yet live to see their faith justified and their patience rewarded, and may even taste some of that so-called "substantial" reward without the hope of which great commercial enterprises would never be undertaken, and modern civilization would have scarcely yet begun.

NEW FORMS OF GALVANIC AND SECONDARY BATTERIES.

European inventors are devoting considerable attention to improvements in batteries, some of the more promising of which may be found described in this article, which has been compiled from different sources.

Among those in which peroxide of lead is used is that of D. Fitzgerald and T. J. Jones. The negative element consists of lead and carbon in contact with peroxide of lead, the peroxide being preferably obtained by the electrolysis of an oxide or salt of lead, or by the conversion of spongy lead into peroxide. When carbon is used as a negative element, it may advantageously be in the form of small fragments surrounding a rod or plate of the same material, the interstices between the fragments being filled with lead peroxide. Lead in a highly porous condition is used for the positive element. It is obtained by a greater or less degree of compression of the metal reduced from its oxides or salts by chemical decomposition or by electrolysis, or by the compression of lead in a state of minute subdivision produced by mechanical means. Dilute sulphuric acid is used as an excitant, which may be improved by holding in solution a small proportion of sulphate or tartrate of ammonia. A new form of carbon battery has been invented by Tommasi and Radiquet, which consists of a rectangular porcelain trough, with a carbon plate at the bottom, surrounded by a paste of peroxide of lead. The other electrode is also formed of a similar carbon plate, upon the upper side of which are placed fragments of platinized retort coke. The two plates are arranged one above the other, separated by a sheet of parchment paper, by which the cell is divided into two compartments. A saturated solution of common salt is then poured in to such a height that the fragments of coke on the upper carbon will be partially immersed. The plate of carbon which does not touch the peroxide of lead is the negative pole. Other saline solutions may be used without materially varying the electromotive force of the cell which is about 0.6 volt.

A battery invented by J. B. Spence and J. E. Chaster, has attained some notoriety because of the claim that it produces a current without expense. This is a copper-zinc battery in which a solution of caustic alkali is used as the exciting fluid, and the depolarizing substance around the copper is oxide of copper. When the spent or partially spent solution is withdrawn from the cells, the zinc therein contained can, it is said, be reclaimed as the commercial oxide of zinc, by passing carbonic acid into the solution which throws down the white carbonate of zinc, leaving carbonate of the alkali in solution. The white carbonate of zinc, when collected, washed, dried and ignited, gives off carbonic acid (which may be used again in another portion of the spent liquid,) leaving oxide of zinc. The solution of the alkaline carbonate obtained by this process may be evaporated, and crystals of alkaline carbonate obtained in the usual commercial form, but it is preferred to boil the alkaline carbonate with caustic lime, so as to convert it into caustic alkali, which when sufficiently evaporated is decanted from the carbonate of lime (formed by the double decomposition in boiling) to be used over again for acting upon a fresh quantity of zinc in the galvanic cell.

Other inventors have devoted their attention to regulating the consumption of zinc and preventing waste of material. The device of Mr. Courtenay is an example of this class. The zinc is coated with layers of asbestos paper previously prepared with an aqueous solution of gum lac, or similar substance, the object being to prevent the wasting of the metal while in the exciting fluid.

Several inventors appear to consider that there is an advantage in making cells with three divisions. Mr. Wenzel of Vienna, patents a voltaic cell consisting of a vessel of impermeable non-conducting material, divided by porous partitions into three compartments. In one of these is placed the positive element of platinum, carbon or the like, immersed in nitric acid of 30° to 40° Beaumé. In another of the compartments is placed the negative electrode, preferably zinc, immersed in a solution of salt about 1 part to 20. The third compartment which is between those containing the electrodes is filled with sulphuric acid of 50° to 70° Beaumé.

A syndicate with a capital of $60,000 has been formed in Paris to exploit the sodium battery invented by M. Jablochkoff. This element was devised for the purpose of obtaining a higher electromotive force than has been the case with any previous invention. Pure sodium in thin plates is used, coupled with compressed carbon, such as is employed in other batteries, or the plates may be placed in a metal capsule, in the midst of broken carbon. Under such conditions and subjected only to the humidity of the air, the battery yields the relatively high electromotive force of four volts, which may be raised to six volts by impregnating the carbon with certain metalloid solutions. This latter fact, however, has no practical value, because the price of such solutions, and the difficulty of using them, make the arrangement quite impracticable. With a couple of sodium and copper, the electromotive force falls to three volts. Such a battery, which may be of value in some cases, is made up of a thin plate of sodium, and a piece of red copper gauze. It will be seen that the force of this battery is considerably in excess of others now in use. On account of the avidity with which sodium decomposes water and absorbs oxygen, it is necessary to shield the battery from exposure when it is not in use, and for this reason it should be kept, except when active, in a bath of naptha, or at all events in a hermetically sealed vessel. M. Jablochkoff asserts that the waste of the sodium, that is to say, its combustion, beyond what is converted into useful energy, is extremely small. One of the objections, which naturally present themselves to this battery, is the great precaution which must be taken in using it, on account of the explosions which occur when sodium is brought into contact with water. With proper precautions, however, such a danger is not great, although more than one serious accident has happened from this cause.

Mr. Sellon has patented an improvement in secondary batteries, which is intended to prevent the leakage of electricity due to the spreading of moisture from various causes, such as through capillary attraction round or over the edges of the plates, or by the condensation of atmospheric moisture, or by the splashing which may occur in charging, and also has reference to modifications in the form of the upper part or edges of the plates in order to arrest the spray which may be given off during formation

Digitized by Google

or whilst charging in the ordinary way, and further to give a convenient form for packing in stacks or columns with ready access to the electrolyte, which may at the same time obviate the capillary attraction, or the effect of the splashing or spilling. For instance, with such forms as annular basin or pyramid shaped or other plates, the edges of which can be so treated, the inventor makes grooves, corrugations, or overlappings of suitable form either at or around the extreme edge or conveniently near thereto, or he casts upon, or works up with the plates, projections, or ridges, or bent portions which may serve an equivalent purpose, and into the space or cavity so formed he places any insulating material of a nature suited to arrest or entirely stop the spreading of the moisture which might otherwise form a junction with the moisture on the adjoining plate. A mixture of paraffine with asbestos, or paraffine alone is very suitable for this purpose.

Another improvement in storage batteries is that of S. Kalischer, which consists in the use of iron for the anode, in combination with a solution of suitable salts of lead, the latter being subjected to the process of electrolysis to produce a dense coating of peroxide of lead upon the iron. This coating, on being metallically connected with a cathode of lead in the liquid remaining after the process of electrolysis, will constitute a secondary battery of high electromotive force from which a constant current of long duration can be obtained. According to the principle of the invention, the peroxide of lead is precipitated upon the anode by electrolysis and by means of secondary action respectively, while the iron, which is employed for the anode remains unchanged.

In the secondary battery invented by M. N. Basset of Paris, any oxide is used which is capable of passing from an inferior to a superior state of combination, as well as any of the chlorides, sulphurets, or phosphurets. The most economical element is composed of two plates of retort charcoal or agglomerated carbon, covered with natural peroxide of iron, or granulated colcothar, wrapped in blotting paper, and held together by cords.

H. Woodward has invented a secondary battery made up of lead tubes rammed full of litharge peroxide, acetate or other suitable salt of lead. The tubes having been cut into the lengths required, and charged with the material, are set aside to allow the contents to dry; they are then pierced with a number of holes to permit the acid and the electric current to act upon the enclosed material.

EVOLUTION OF THE ELECTRIC RAILWAY:

ITS COMMERCIAL AND SCIENTIFIC ASPECT.

BY DR. WELLINGTON ADAMS.

(Continued from page 268, Vol III.)

As I have already stated, the most important application of this principle of electric transmission of power is exemplified in the *modern* electric railway. Now, I advisedly use the expression *modern,* because the electric railway, like all other inventions, has a history. It is not a thing of spontaneous development, but of gradual growth. In considering its evolution, we must cursorily glance over the history of the "*electric engine,*" as electro-dynamic machines have heretofore been christened. The earlier "electric engines" or motors belonged to that class or type known as oscillating or reciprocating engines. First to make an oscillating electric motor was a learned monk, strange to say, of Padua—Salvator del Negro, who, in the year 1831, succeeded in operating such a motor. An oscillating motor, however, has many disadvantages, the most important of which is the fact that the moving part (the "armature") at the end of its stroke is at a considerable distance from the attracting electro-magnet (the "field"). This, in electric motors, is a very serious defect, since the electro-magnetic attraction or pull diminishes in intensity very rapidly, varying, as it does, inversely as the square of the distance; so that when the armature begins to approach the field there will be very little, if any, force pulling it. Hence motors built upon this principle proved very little more than pieces of physical apparatus. The first motor for producing rotary motion by electro-magnetism, without a reciprocating action, was invented in 1833 by our now deceased countryman, Prof. Henry, late of the Smithsonian Institution, a description of which may be found in Vol. XX. of Silliman's Journal.

This motor also was but a toy, having the same defect just referred to, as indeed did all motors brought out up to the time of the discovery of the modern "dynamo" principle. Between the time of the advent of Henry's motor and the period of Prof. Page's experiments, of which we shall learn further on, Davenport in our own country, Prof. Jacobi in Russia, Davidson in Scotland, and Mr. Henry Little in England, constructed electric motors of considerable size. Prof. Jacobi propelled a boat by electricity on the Neva, at St. Petersburgh, in 1839; Davenport and Ransom Cook had quite respectable electric motors working in New York in 1840; and Davidson ran an electric locomotive in 1842 on a railroad near the city of Glasgow, Scotland. A little later, Mr. Little operated an electric locomotive in England. Jacobi's motor was of about two h.p.; that of Davidson was a little over one h. p., and propelled a locomotive weighing five tons at the rate of four miles an hour. Excitement upon this subject reigned supreme in New York about 1841, when electro-magnetic engines became a kind of mania, and although commercially worthless, hundreds of them were manufactured to meet the market demand.

The experiments of Jacobi, Davenport and Davidson proved unsatisfactory however, as was predicted by contemporary scientists. This, naturally, caused disappointment and reaction; so that nothing of importance was added to the stock of knowledge concerning the subject until 1845, when Prof. Page, of Salem, Mass., revived and gave to the subject a new impetus by the invention of a new form of electric engine based upon the principle of the axial force of electro-magnetism, which proved to be the most perfect electric motor ever invented up to that time. A few years later, Prof. Page proposed electricity as a motive power for railroads, through the instrumentality of his own electric engine. This engine proved so successful and attracted so much attention that the idea gained favor to such an extent as to induce Congress to appropriate and place at Prof. Page's disposal a sum of money (thirty thousand dollars) adequate to construct and operate an electric locomotive in accordance with his plans. Such a locomotive was built in 1851, and used to propel a train of cars between the cities of Washington and Bladensburg, a distance of five miles. As was natural, such an undertaking created great excitement and discussion in the scientific world, both at home and abroad, more especially because of the governmental sanction and assistance lent the enterprise. The great mathematician and scientist, Dr. Joule, and many others, very properly contended that the system would be too expensive, and that electricity as then generated, could not be used as a motive power with sufficient economy to warrant its adoption on a commercial scale. In fact it was this very discussion which led Dr. Joule to that long and laborious investigation of the mechanical equivalent of heat, which now forms the basis of all our work in thermo-dynamics, and without which we should be groping in the dark.

It was on the 29th day of April, 1851, that Dr. Page made the trial of his locomotive, which ran at the rate of nineteen miles per hour, making the trip of five miles in thirty-nine minutes. The locomotive itself weighed ten and one-half tons, including the batteries, and carried seven passengers. There were many stops and delays on account of the breakage of his battery cells, which were carried up-

Digitized by Google

on the locomotive, the jars fulfilling the office of a steam locomotive boiler and furnace, zinc and sulphuric acid in the former case constituting the fuel. The sulphuric acid and zinc were burned or consumed in the production of electricity. This is the principle upon which it was sought to operate all the electric engines thus far referred to. Electricity was here called upon to serve as a prime motor, utilizing the energy stored in sulphuric acid and zinc.

The folly of such an error is manifest, since one pound of zinc costs twenty-five times more, and is not capable of being transformed into as much dynamic force, as one pound of coal. Although Dr. Page's hopes were not realized as far as refers to the commercial aspect of the enterprise, he nevertheless accomplished a great feat, and to the day of his death he contended that the time would surely come when electricity would be economically used as a motive power upon railroads.

Ever since Dr. Page's memorable experiment, thoughtful people have been looking expectantly and anxiously forward to the fulfillment of his prophecy. The time is now ripe for such fulfillment. In fact, it has even now passed from the stage of speculation and become *au fait accompli*, many miles of electric railway, notwithstanding their primeval crudity, now being in successful operation on a commercial scale in different parts of the world.[1]

You ask, I imagine, "What has rendered possible at this day that which was thirty years back demonstrated impracticable; and in what respect does the *modern* electric railway differ from that of the past?"

My answer is: that which has rendered the electric railway commercially feasible, is the discovery by Messrs. Varley, Siemens and Wheatstone, and the subsequent development by many others, of the dynamo-electric machine; and the further discovery or demonstration by MM. Fontaine and Gramme of the reversibility of that machine, which admits of its being transformed into the most efficient form of an electric motor, when a suitable electric current is passed through it. The *difference* between the ancient and the modern electric railway, consists in the fact that whereas the effort was formerly made to use electricity as a *primary* motive power originating from the consumption of zinc and acid, we now use the electric engine or electro-dynamic machine as a *secondary* motor, and the electric current simply as a means of *transmitting* power procured from natural sources or previously generated by any of the known economic methods, if some natural source of power is not at hand. Such a system contemplates the establishment of a central fixed station, where large steam boilers and engines of the most economic type are erected and used to set in operation dynamo-electric machines, which generate powerful currents of electricity. These currents are in turn transmitted through a copper conductor running along the roadway, and, by means of a moving contact, they are taken up into the cars while the latter are in motion, and there passed through an electric engine or electro-dynamic machine, which operates to propel the cars. This idea of the generation by dynamo-electric machines of powerful currents of electricity at stationary points, and the transmission of these electric currents to cars while in motion for the purpose of effecting their propulsion, was first put into execution in 1879, by Dr. Werner Siemens and myself, both of us working independently and mutually ignorant of the other's doings. I constructed a small model, such as was within my limited means, and used the same to demonstrate a lecture on electricity delivered at the time in Colorado Springs, Colorado; about the same time Dr. Siemens exhibited a more extensive model at the Paris Exposition.

In my system the method of applying the power was very different from that adopted by Dr. Siemens; my only object then being to demonstrate the principle of electric transmission of power to a moving car for the purpose of propelling the same. On receiving news of the work of Félix and Chrétien at the sugar plantation at Sermaize, they having resorted to electricity as a source of power for plowing, I was more than ever impressed with the value of the system and of the future which lay before it, and I accordingly began experimenting upon and studying the subject up exhaustively, going thoroughly into every detail.

Although at the time actively engaged in medical practice, and connected with the Medical College in Denver, so great were the allurements, I was induced to give everything up in Colorado and leave there rather precipitately for Washington, in quest of a generic claim upon this fundamental principle. My case being examined, it was, however, found that the same principle had been *proposed* and provisionally patented, although not put in operation or even demonstrated and made public, as far back as 1840, by one Henry Pinkus, a remarkably inventive genius of that period. In 1840, however, the dynamo was unknown, and the electric car motors of Pinkus, which existed only in his imagination, were *supposed* to be operated by galvanic batteries buried in the ground. The principle of the transmission of the current to the car while in motion for the purpose of effecting its propulsion was, however, the same. The inventor even went so far as to anticipate the future use of "mechanical generators, which should be more economical" than the batteries.

Dr. Siemens and myself are consequently antedated as regards the question of first conception of this broad principle, and the underlying feature of the *modern* electric railway becomes public property. My application for a patent upon this fundamental principle is a matter of record in the United States Patent Office. This application was abandoned on discovering the record of the Pinkus patent. Appreciating, however, the rich harvest in store for inventors in this new field who should devise the most practical and economical means of applying this principle, which comprehends an army of important details, I immediately began research into the necessary conditions to a successful solution of this most intricate problem. The results of this investigation, which has cost many thousands of dollars, will, I hope, in your judgment, prove meritorious.

We may, of course, crudely mount upon a car a dynamo-electric machine of our own or another's design, and connect this up with the wheels or axles of the car by means of cog-wheels or belting, and thus effect the propulsion of the car, temporarily for exhibition purposes, regardless of the cost or of practical commercial requirements, as several have done since the first public exhibition of the modern electric railway by Dr. Siemens and myself, the individuals in each instance styling the result as "their electric railway," which as a matter of fact differed, figuratively speaking, but by a bolt or a nut from Siemens's original road.

(*To be continued.*)

FIRST PRINCIPLES FOR YOUNG MECHANICS.[1]

BY COLEMAN SELLERS.

A well grounded knowledge of the great law or principle of conservation of energy should be taught with the multiplication table. It can be so taught if the teachers themselves are certain that there is in the universe only so much energy, and that we cannot make one particle more than already existed. With a clear understanding of this principle, no time will be wasted in search after perpetual motion machines, and fewer mistakes will be made by really earnest seekers after improved machines for use or improved methods. When a young man brings to me some wonderful improvement over the ordinary crank motion,

1 Page's motor in operation and stereopticon views of the others were here introduced.

1. *Scientific American.*

Digitized by Google

some device that is to supersede the crank of the steam engine, a feeling of utter helplessness comes over me; I know not where or how to begin; he has had no opportunity to learn the simple laws of mechanics, and to point out the fallacy of his argument means to teach him the laws of mechanics, so I can only say to him, "Don't," and may advise him what books to read.

We hear or read almost daily of the wonders of science, and what is to be accomplished by electricity. "It is to be the great power of the future." Is it a power now? We may use it indirectly to drive machinery, we may make use of it to propel the cars on our street roads, but is it a power in the sense that steam is a power? Let us think of this a few moments. We call steam a power, and our factories are driven by steam power; or we call water when falling a power, and we drive the machinery in other factories by water wheels; or we pump water into the reservoirs at Fairmount by water power. Where we have no fall of water, and where fuel is scarce but wind plenty, we grind corn in a mill driven by wind, and the wind is our power; these and other sources of power may be called primary powers.

Secondary power is that which is transmitted from the prime motor to a machine. One machine may be driven by belt power, and another may be driven by gearing, etc. Electricity, as we now use it, as a power must be classed in its greatest economy with the secondary powers, with the belt or the gearing, not with the steam engine and the water wheel. We dig from the earth coal that contains the stored up energy of the sun's heat expended on forests that existed long before man came to live on this planet. We burn that coal under our boilers, and the steam generated by this application of heat to water is used to drive the piston of the steam engine, and from thence is the power conveyed by belt or gearing by shafts, or even by electricity, to the machines to be operated. We can burn up zinc in costly acids, and generate electricity that can be used to drive an electric engine, and so in turn operate machines exactly as in the case of the steam engine. In this case electricity is a power exactly as steam is to be considered as a power; and what is more, the electric battery will give us more nearly the whole of the stored up energy of the metal eaten up in the battery than the most improved steam engine can give us of the stored up energy of the coal that is devoured in the furnaces under the boilers. With all this advantage, electric batteries are not used to drive machines with any hope of economical results.

Zinc has been gathered from the earth as an ore, it has been converted into a metal, or the metal has been gathered from the ore by means of coal and much labor; its market price is measured by the cost of its production. To burn up zinc at 5 cents a pound in acids costing but few cents per pound, with a certainty of getting from the metal 70 or 80 per cent. of its theoretical energy in motive force, yet makes the venture a more costly one than the burning of coal under a boiler with the knowledge that we are at the best getting but little more than 10 per cent. of the theoretical power that lies hidden in that coal. The electricity that is now lighting our streets, the electricity that is utilized in places to drive the street cars, has behind it the steam engine or the waterfall, the windmill, or some other motor.

By means of a steam engine we drive a dynamo electric machine, and the electricity thence proceeding lights our streets or may be reconverted, with some loss, back into the power that created it; for one dynamo machine can be made thus to drive another, the electricity being carried from one to the other by proper conductors. What, then, is electricity as we now use it in the way of power, but as the belts and the gearing that carries our steam power to the machines? It is a belt with more or less slip. But this is not to remain so forever. The future of electricity as a power is full of promise. The coal we now squander, using but a small percentage of its theoretical dynamic force, is capable of yielding its energy either as heat or as electricity; and the time will come when we will not burn this coal to boil water, and in that boiling lose say 1,000 units of its heat at the moment of the conversion of water into steam, lose all this, never to be getting it back, but we will take from the coal its energy in the form of electricity, we hope in more near ratio to its true value, and then we can convert that energy into whatsoever other form of energy we may require. The best that science can do is to point out just what energy there is in this or that source of power. The most we can hope to utilize of this energy as power will never amount to 100 per cent. Nature gives us nothing without exacting something in payment.

A pound of water is the same as a pound of metal so far as its power from gravity is concerned. In falling through space it will exert just as much force as any other pound weight is capable of doing, and no more; it will do the work due to 1 pound falling at any given velocity less the friction of the machine or of the moving parts. We turn water into steam with a certain knowledge of the power that can be gained by using the elastic vapor as a spring, or we may tear the gases, which combined form water, apart, and use these gases in recombination to produce power, but less power than was taken to tear them apart, never more.

Science has made us so sure of these facts that we can base our faith on them, and with this knowledge we are willing that others than ourselves shall invest their money in machines which are claimed to be able to develop from five drops of pure water inclosed in a ball, power enough to propel the largest steamship across the ocean. It is ignorance of the unalterable laws of physics that leads ignorant people into squandering money on so-called wonderful inventions that, out of nothing, are to give us great results. An ignorant man will spend his time pondering over perpetual motion machines, so will a man with brain gone wrong; the first will quit his folly with more learning, the second finds his home in a madhouse. A third and worse class aim to deceive, and, for a time, many a one has done so. When shrewd ignorance resorts to dishonest methods, the confiding public is apt to suffer in pocket

THE METRIC SYSTEM.

We call the attention of our readers to the following remarks by Sir William Thomson during an address at Philadelphia last summer: "You in this country are subjected to the British insularity in weights and measures; you use the foot and inch and yard. I am obliged to use that system; but I apologize to you for doing so because it is so inconvenient; and I hope all Americans will do everything in their power to introduce the French metrical system. I hope the evil action performed by an English minister, whose name I need not mention, because I do not wish to throw obloquy on any one, may be remedied. He abrogated a useful rule which for a short time was followed, and which I hope will soon be again enjoined, that the French metrical system be taught in all our national schools. I do not know how it is in America. The school system seems to be very admirable, and I hope the teaching of the metrical system will not be let slip in the American schools any more than the use of the globes. I say this seriously. I do not think any one knows how seriously I speak of it. I look upon our English system as a wickedly brain-destroying piece of bondage under which we suffer. The reason why we continue to use it is the imaginary difficulty of making a change, and nothing else; but I do not think in America that any such difficulty should stand in the way of adopting so splendidly useful a reform."

ELECTRIC RAILWAY PROSPECTS.

VIEWS OF EMINENT ELECTRICAL EXPERTS.

THE possibility of the practical application of electricity as a motive power for such an important service as that of the elevated railways in New York city, has awakened renewed interest in this subject. Under the auspices of the *Mail and Express,* several interviews have been made public, which contain information of interest and value to all electrical workers. In a letter to Cyrus W. Field, Prof. Moses G. Farmer gives the following summary of the history of electro-locomotion :

MY DEAR SIR.—Now that the application of electricity to the elevated roads is agitated, it occurs to me that it may be interesting to glance at some of the steps in the progress of discovery and invention which made electro-locomotion possible in 1850 and practicable in 1883-4. It was in 1819-20 that Oersted, of Copenhagen, discovered that if a wire carried a current of electricity from south to north over a magnetic needle, it caused the north end of the needle to be deflected towards the west, and also, if the current passed from north to south under the needle, the deflection of the north end of the needle was still towards the west.

It was not long before Schweigger carried the wire and current several times over and under the needle and thus invented the galvanometer. Before 1826 Sturgeon had wound a wire several times around a bar of soft iron, and, when a current of electricity was sent through the coiled wire spiral, it made a temporary magnet of the iron bar, which magnetism remained as long as the current was flowing. Soon after, as early as 1831, Faraday discovered the principal facts of magneto-electric induction, and thus made the magneto-electric machine possible in the hands of Pixii in 1832. The Daniell and the Grove batteries soon after appeared, and in 1839 Jacobi, at St. Petersburg, constructed a boat which he propelled upon the river Neva with a two-horse power electro-magnetic engine, actuated by a Grove battery which had in it twenty square feet of platinum surface.

In 1840 Davenport and Cook, of Vermont, constructed a walking-beam engine with which they drove a printing press, using a zinc and copper battery with a solution of blue vitriol as the exciting liquid.

In 1842 Davidson, of Scotland, constructed a five-ton electric locomotive, which he propelled at the rate of four miles per hour with seventy-eight pairs of zinc and iron in sulphuric acid solution, the plates being thirteen inches square.

In 1844 Channing conceived the idea of substituting an electro-magnet in place of the permanent steel magnet in the magneto-electric machine of Pixii, and the further idea of using this electro-magneto electric machine to excite the field magnets of a still larger electro-magneto electric machine.

(This idea was subsequently, in 1863-6, further elaborated by Henry Wilde, of Manchester, England.)

In 1847 I constructed and exhibited in public an electro-magnetic locomotive, and with forty-eight pint cup cells of Grove nitric acid battery drew a little car carrying two passengers on a track a foot and a half wide.

In 1850 Page, of Washington, constructed an electro-magnetic engine of 16 h. p., and with a hundred cells of Grove nitric acid battery, each having platinum plates eleven inches square, he propelled a car carrying a dozen or more passengers on the Washington and Baltimore Railroad at the rate of nineteen miles per hour.

In 1851 Thomas Hall, of Boston, (then at work for Daniel Davis) constructed, and later exhibited at the Charitable Mechanics' Fair in Boston, a small electric locomotive which took its current from a stationary battery by means of the rails and wheels, as the following extract from a letter written to me by him, November 25, will show : "In the year 1851, when I was at work for Daniel Davis, I made a small electric locomotive, which ran on a straight track about twenty feet long. The wheels were insulated and the electricity was conveyed to the engine by means of the rails from two Grove batteries. The cut-off was in the engine and worked automatically or by hand, so that when the engine reached the end of the track, the switch reversed the engine and it went back to the starting point. In 1860 I exhibited in the Mechanics' Fair a small locomotive called the Volta, very finely made and finished, which ran on a circular track about eight feet in diameter. The current was conducted to the insulated wheels from two Grove batteries by means of the rails. I have a part of one of these engines on hand now, and photographs of the Volta; also wood-cuts of the first ones which were published in a catalogue between 1851 and 1860."

I asked Mr. Hall's permission to publish his letter, and in reply he says : "Shall be glad to have you publish the facts as I have stated them to you, and shall be obliged to you for doing it. You know they are facts as well as I do."

These four engines, therefore, of Davidson, Farmer, Page and Hall could be started and stopped, sent forward or backward, at the pleasure of the engineer.

In 1859 I conceived of the self-exciting dynamo, which I constructed in 1866 and which was also conceived of by Wheatstone, Siemens and Ladd in 1867 and by Gramme in 1871, so that by 1871 cheap electricity became possible, and nothing more was needed except to substitute the dynamo machine for the galvanic battery to make electro-locomotion both possible and cheap, and yet the invention slumbered on for a decade or more.

Now, in 1884, a host of inventors, by simply substituting the now well-known dynamo for the more expensive and troublesome acid battery, appear to be just on the eve of bringing to blossom and fruitage those buds of promise after their long forty years of germination, because there was then no demand, no elevated roads, and so they came not forth.

There are two principal methods of propelling an electric locomotive: 1st. The engine carries its source of electricity, such as a galvanic battery, as did Davidson's, Farmer's, and Page's. 2d. It is picked up from a stationary source by means of the wheels and rails, as did Hall's.

In the later days, since the advent of the storage battery, the supply of electricity can be economically carried on a tender, and it is worthy of very patient and long experimental inquiry, which method is the cheaper—to lay a third rail to carry the current to the locomotive, or to charge the storage battery, place it on a tender and attach it to the locomotive.

Respectfully yours,
MOSES G. FARMER.

NEW YORK, Nov. 29, 1884.

In a subsequent interview, Prof. Farmer gave further details of his personal experience, as well as his opinion of practical success in the proposed application of electricity, which is reported as follows :

"I constructed an electric railway nearly 40 years ago. It was only a toy affair, but I thought I had discovered how to make a million or two in a week or two. I expended much time and money, and my contrivance attracted attention throughout the whole country, and was exhibited in several cities. I was a teacher at Dover, N. H., at the time, and I suppose Morse's invention of the telegraph turned my thoughts to electrical enterprise. It was in 1846 that the first telegraph line was built from Boston to Portland, and at the beginning copper wire was used, but it sagged so much that iron was substituted for it. I bought 300 pounds of the discarded wire for my experiments. A man by the name of Davenport had used electricity to operate a printing press in Vermont, and that fact probably helped to convince me that it could also be applied as motive power for railway trains."

"What kind of a motor did you use ?"

"An electro-magnetic motor. The Grove battery was then the most successful invention of its class, and the one I used contained 50 cups and consumed 8 pounds of the acid and zinc per hour for every h. p., the cost being 15 or 20 cents."

"Why did not your scheme succeed ?"

"The power cost too much. In 1850, 3 years later, Page constructed a similar motor with 100 cups, and the government gave him $20,000 for its development for use in the navy, but he did not succeed any better than myself. My enterprise decided the course of my life, however, for I have been engaged upon electrical problems pretty much ever since."

"And have you retained your faith in the practicableness of operating railway trains by electric motor ?"

"I have, and there is reason to expect that its demonstration will soon be witnessed on the elevated railways."

"How would you advise the Manhattan Company to proceed to effect that result ?"

"In the first place, much skill will be required in the test for the selection of a motor."

"But has that not been provided in the expert commission chosen to appraise and consolidate the rival motor interests ?"

"Yes, the members of the commission are satisfactory, if only they will serve, but I do not see how Sir William Thomson can spare the time for the service, unless he is offered a great pecuniary inducement. However, it may take 6 months to prepare the track and motors, so that he

Digitized by Google

can devote his summer vacation to it. It might take 60 days for the test after all is ready."

"Have you studied the elevated railways with a view to the change from steam to electricity?"

"Yes, I have had my assistant examine the Ninth and the Third avenue lines. It seems that there are frequently 20 to 25 trains on each track at one time, and each locomotive has about 40 h. p., they say. Of course it will require 20 times as much electricity to move 20 trains as it would to move 1 train."

"Do you mean that a greater force will be required than can be applied with safety?"

"No, not if the proper methods are employed. I do not care to say at present what those methods are, for I am making investigations which I am not yet ready to disclose. I will say, however, that the trackmen will need to wear dry rubber shoes, and even then it may not be comfortable to touch both rails at the same time."

"Will the size of the rail make any difference as to safety?"

"Yes, the larger the rail the less the risk. The central rail should be at least 70 pounds, and the Manhattan Company may be glad if it is not found necessary to take up the 50 pound rails now in use and lay a much heavier track."

"How much cheaper will electricity be than steam power?"

"It all depends upon the system used. There ought to be no difficulty, however, in saving 100 to 140 pounds of coal per hour on each of the 40-horse locomotives now in use, if their consumption of fuel has been correctly represented to me. Stationary engines are much more economical than locomotives, and in Lowell, Mass., a steam pump is operated by only $1\frac{3}{4}$ pounds of coal per h. p. per hour, and I have no doubt the Manhattan Company can save much labor as well as fuel by the proposed change."

"Do you expect to see electricity substituted for steam on surface railways?"

"The problem becomes more difficult when transferred to surface lines, certainly, and I am not prepared to say what I expect, either as to the great freight and passenger railways or as to the street car lines of cities."

"Do you believe, like Mr. Edison, that some one will discover how electricity can be generated directly from coal?"

"The thermo-electric battery to which I devoted so much attention, especially from 1865 to 1868, was too expensive, and it converted not more than $\frac{3}{10}$ of 1 per cent. of the energy of coal into electricity. One of my batteries cost $1,000, and was used to apply the copper to the first compound wire ever made, but it gave no key to the economical production of electricity directly from coal, nor has any other contrivance of which I have yet heard."

Prof. Morton, President of the Stevens Institute of Technology at Hoboken, while entirely convinced of the feasibility of the proposition, strengthens his opinion by carefully refraining from enthusiastic exaggeration. He is reported as saying:

"I think some of the electricians are wild in their estimates, but I am convinced that electricity can be advantageously introduced on the elevated railways of New York. I have read the recent newspaper articles on the subject, and while I think it necessary to make a large allowance for exaggeration, I heartily concur in their general conclusion that the scheme to substitute electricity for steam as motive power on the lines of the Manhattan Railway is perfectly feasible. I should not put the maximum of saving at more than 30 per cent., and the actual amount might be much less. I see that most of the men who have motors to introduce make the minimum about 30 per cent. and confidently predict a saving of 50 per cent. I should say that the cost of generating steam in a stationary engine and in a railway locomotive is as one to two. Clarke, a very high English authority, gives as a result of numerous experiments what is equivalent to 5 pounds of coa per h. p. per hour as the efficiency of locomotives, and recent experiments of the Pennsylvania Railway support his conclusion. As I have said, the plan to operate the elevated railways by electricity is perfectly feasible, and the economy of the new system would doubtless be very important, while the removal of smoke, dust, and some other disagreeable features of the present system would of itself afford adequate compensation for the change, were there no pecuniary advantage to be derived from it."

"The Siemenses use a dynamo as the motor on their electric railways in Berlin and other European cities, and each of the rival motors is a dynamo in a modified form. There is a double magnet surrounding an armature, and the current of electricity passing through the mechanism of this machine on its way from the central rail to the outer ones, by which it is to return to its source, causes the armature to revolve by magnetism, and thus the machine is made to move."

"Is there danger in its use?"

"No, and the current of electricity required would not be strong enough to do injury, either by causing fire or shock. Care should be taken, however, to secure uniformity of current, and there is a great difference of the dynamos as to the production of a uniform current. A force of 1,000 volts, if the current could be made uniform, would not be unsafe, I think, but of course no such force is contemplated in the estimates of the owners of the motors."

"Is a third rail necessary?"

"It would be possible to use one of the ordinary rails to carry the current and the other to return it, but this would require insulation of the rail and of the car wheels, making the problem more difficult. An insulated third rail for that service would be much better. I do not believe that electricity can be profitably substituted for steam on ordinary railways, at least for the present. Improved methods of generating electricity may ultimately make the change economical, but science has not yet made electricity available as motive power for railways, except on short lines. It is absurd, too, for electricians to talk of applying electricity on surface lines without an insulated track. Much of the calculation of enthusiastic inventors will be found seriously at fault in practice, I fear. Short lines which have numerous trains can be successfully operated by electricity, but the same cannot be said of ordinary surface lines."

"Are you also skeptical as to the substitution of electricity for horse power on tramways?"

"I do not see any reason to believe that the change can advantageously be made. The difficulties to be overcome are numerous, and some of them are of a very serious character. I doubt if the change will be made for many years to come."

Prof. Charles R. Cross of the Massachusetts Institute of Technology, who has been asked to serve upon the commission of experts, pointed out some of the difficulties which would be encountered in deciding upon the most satisfactory system to be adopted.

"There is much disagreement," he said, "even among experts, as to the methods of testing electrical apparatus, and it is difficult to secure an agreement as to the comparative merits of electrical machines. However, the Philadelphia Exhibition did much toward the establishment of correct methods of making tests, and I regard the testing of dynamos there as the most satisfactory work of the kind yet done. It will be more easy for the expert commission to perform its allotted task because of the tests made at Philadelphia, but it may require considerable time to determine what motor is best and what system should be introduced."

"If electricity can be substituted for steam as motive power on railways there will be a vast amount of money for the inventor who produces the motor which performs the desired service."

"But do you doubt that the achievement is possible?"

"I do not say that I doubt its possibility, and I will say that

Digitized by Google

I think electricity can be advantageously substituted for steam on the elevated railways if anywhere, but there are so many things connected with the enterprise which are yet to be determined that I am not willing to express any opinion as to the results of the experiment."

"You may say that I think the change from steam to electricity will be advantageous pecuniarily, but I will not venture any prediction as to the per cent. to be saved. I think the problem to be considered by the commission is extremely important, both scientifically and pecuniarily, and I prefer to hold my opinion in reserve until investigation has removed some uncertainties which now enter into the case."

"Have you no prediction to make for the encouragement of the railway men who wish to apply electricity as a motive power?"

"Mr. Lowell says: 'Never prophecy unless you know,' and I think his rule is a safe one for me in the case you now present."

"What is the chief factor in the problem—the amount of power required, or the cost, or the risk to life and property?"

"Each of the three factors is important, but I do not think there will be danger in the use of electricity to move railway trains if proper precautions are taken."

"What force can be used with entire safety?"

"I should not hesitate to receive the shock of the current used on most of the electric railways now in operation, although their traffic is nothing like that of the New York elevated railways."

"What force would be required, supposing the number of trains on one track at one time to be 25 and the power of the locomotives now in use to be 40 horse?"

"It would be easy to make an accurate estimate, but without going into a careful calculation I should say roughly about 500 volts with a 1,500 ampère current. That would be approximately the equivalent for the steam power now employed, not taking into the consideration the element of waste in heating the wires. It might be advisable to use lower electromotive force and a higher current."

"But the inventors of the motors do not contemplate the use of so great a force?"

"It remains to be seen whether their expectations will be realized. However, there ought to be no danger in the use of even a much stronger current than I have mentioned."

"And as to the cost?"

"That must be ascertained by a test. The problem is to obtain the maximum of energy at the minimum of expense. The earlier dynamos were constructed with a great internal resistance, but that resistance has been much reduced in the recent inventions. The water-wheel gives the greatest per cent. of the original energy, and in some wheels it is as high as 95 per cent., but the recovery in some of the dynamos is said to be as high as 90 per cent., so that the prospect, from an economical point of view, is encouraging."

There are few people so well qualified to judge of the successful and economical transmission of power through the agency of electricity as Mr. Edward Weston of Newark, N. J. After briefly narrating his preliminary experience in the electrical field, he said:

"I do not wish to appear too sanguine, but electricity is certainly destined to play a much more important part in the economy of civilized life than most people dream of. The crudity and wastefulness of our principal motor, the steam-engine, is very seldom thought of by any except those who have made a special study of the subject. This apparently perfect piece of mechanism wastes nearly 80 per cent. of the energy of the fuel. The dynamo-electric motor would change all this, if we could convert the energy evolved in the combination of coal with oxygen directly into electricity. The dynamo machine will convert more than 90 per cent. of the power transmitted to it into useful energy, and good electric motors would certainly not fall far short of it.

"I suppose that the capital now invested in electrical enterprise, aside from telegraphy, is not less than $100,000,000. And the transmission of power I regard as a much more important branch of electrical enterprise than that of furnishing illumination. It is hardly true, as President Morton, of the Stevens Institute, says that 10,000 mechanical engineers are needed for every ten electricians, and certainly the development of electrical enterprise which the future promises must excite the keenest anticipations."

"How do you arrive at your conclusion that the transmission of power is more important than the production of light by electricity?"

"It is true that the transmission of power by electricity is still in its infancy, but the United States company would be willing to take a contract for the operation of the trains of the elevated railways by electricity, and as long ago as 1880, I made estimates which I presume to be still in the possession of the Manhattan company or some of its representatives.

"But in the operation of light machinery electricity is a safer, more convenient and more economical agent than steam. The small steam-engines now in use are expensive and not altogether safe, and it would be better for all concerned to remove them and substitute electricity.

"Dynamo stations would be required in districts of convenient size, with wires to transmit the power to consumers. A small dynamo—that is, a motor, which is a dynamo reversed—would be needed by each consumer, but its cost would be less than that of a steam engine of equal power, and it would require no fuel and could be controlled as easily as is an electric lamp.

"Ten h. p. engines and all smaller ones cost their owners more than would their equivalent of power in electricity. The United States company will extend its business in the transmission of electricity as power for light machinery as fast as possible."

"Your confidence in the electric motor is doubtless sufficient to enable you to give a favorable opinion as to the feasibleness of the substitution of electricity for steam as a motive power on the elevated railways, then?"

"I have no doubt whatever that the change can be made with advantageous results in more than one direction."

"Let me give you a problem. Suppose that on one track of the 'L' there are at one time 25 trains, each drawn by a locomotive of 40 h. p. What will be the force of electricity required as a substitute for the locomotives to move the trains?"

"It depends upon the pressure as related to the current. But a pressure of at least 500 volts can be safely used, with the proposed 70 pound central rail, and with that pressure a current of not quite 1,500 ampères would be required as an equivalent for 25 locomotives, each of 40 h. p."

"What size stationary engine and what dynamo would be required to furnish that force of electricity?"

"It would be unwise to use one dynamo to generate that amount of electricity, and about 6 dynamos, each of 200 h. p., would be needed. For the operation of these dynamos a stationary engine of 1,200 h. p. would be adequate."

"And what would be the expense?"

"The rule is that a stationary engine of the best kind costs $50 per h. p. annually, and at that rate the entire expense would be $60,000 a year. But there is this difference between a locomotive and an electric motor. The former has only its minimum power at the start, while the latter has its maximum, and so the locomotives need to have 40 h. p., although the average power required may not exceed 25 horse."

"There are great mechanical difficulties in the case, I admit," said Mr. Weston, in reply to a question, "but what great invention has been introduced without overcoming great mechanical difficulties? The introduction of gas is a good illustration. The opposition to its use was so great that its substitution for the old light was retarded nearly twenty years, and it is now very amusing to recall the objections which were made to it. Dynamite is hardly regarded with more dread now than was gas by many people less than a century ago. Only fifty years ago the citizens of Philadelphia passed resolutions entreating the Common Council not to permit the use of gas in that city, mainly because it was thought to be dangerous. The obstacles to the application of electricity as motive power are certainly not greater than were those encountered by the men who established the system of gas light."

Mr. Edison has also given his views upon the subject through the columns of the *Sun*, by which it will be seen that he considers the economy of electric locomotion settled, and that its immediate application is simply a question of proving it to the satisfaction of the management. He says:

"The application of the electric motor to the car is simple, and could be effected in no time if the men could be found with nerve enough to advance the money. It will need two stations to keep the current on the tracks. I could build one at Washington Park and one near 42d street, and keep all the trains in motion without any trouble, including switching and stops. It can be so arranged that all power will leave the trains as they approach on the same track, and so collisions will never occur. Speaking practically, I will take the 160 engines of the Manhattan company and put half of them in one of the stations I spoke of above and half in the other, to run the dynamos which will furnish a current of electricity. I will then buy enough old rails to reach from the Battery to Harlem and will set them up between the tracks of the elevated road. Wires from the two stations will be connected with this long railing, and the electricity will flow through it. It will be led to the electric motors and after furnishing power to run the train, will be allowed to escape through the regular rails of the road."

Digitized by Google

"What will be the saving to the Manhattan company?" Mr. Edison was asked.

"They will save in the number of employés necessary, for one man at each of the two stations can run 15 trains. One man can run the electric motor. The saving in coal will be very great. They can use more economical boilers than at present. To-day their property is depreciating on account of the great wear and tear. The power is now applied explosively, in jerks. There is a terrible racking of the whole structure. They might as well explode powder all along the line as to run as they do now. Electricity, on the other hand, is a continuous, velvety motion. There is no jar and no wear and tear to the structure."

"How soon can the change be made?"

"As soon as the money is forthcoming. The motor has reached such a degree of perfection that nothing more can be done to it in the laboratory. It is now only a question of mechanical engineering, or a draughtsman's work, to apply the motor to the elevated road. An experiment is likely to be made soon on the Second avenue line. If they let me put up my centre railing I can run my electric train right in with the others and not interfere with the steam trains."

"Will any other improvements be made in this connection?"

"There is one that ought to be made now, whether they have an electric road or not. I can increase their travel enormously if they will let me put in an electric elevator at each of the stations. Women will not ride because their clothes are so heavy they can't climb those frightfully long stairs. Old men can't get up there. Just think how nice to step on a platform and rise quietly to the station and come down the same way! Thousands who don't ride now would flock to the roads. The people of New York expend 26,250 h. p. in an hour climbing those stairs. The force consumed averages 2,187 per hour for the twelve hours of the day. Let me figure for you. The report of the Manhattan company says that they carried 50,000,000 people last year. We put these people into pounds, at 150 pounds each, and have 7,500,000,000 pounds. But they must be raised to the platform, which is twenty-five feet high at least, and that gives us 52,500,000,000 pounds raised one foot. The h. p. for an hour is 2,000,000 pounds raised one foot. If all those people were raised to the stations in one hour that would be an expenditure of 26,250 h.p., and dividing by twelve for the twelve hours of the day we get an average per hour of 2,187 h. p. expended by people in climbing those stairs. Why, that is about one-fifth the total power expended in running the whole elevated road. But people don't seem to mind it much—man is such a perfect motor, you see."

ABSTRACTS AND EXTRACTS.

TRANSMISSION OF POWER BY ELECTRICITY.

One of the most successful examples of the transmission of power for industrial purposes by electricity which has yet been made, is described in a recent number of *La Lumière Electrique*. The thriving manufacturing city of Bienne is situated on the Suze, a tributary of the Aar, in Switzerland. The river Suze, which descends from the heights of the Jura, for the greater part of its course is a veritable mountain torrent, but at a distance of about 2 km. from Bienne, it reaches the level land at the foot of the mountains, and is suddenly transformed into a sluggish stream. Several years ago a system of high pressure water works was established in Bienne, deriving its supply from above the lower falls, and not only furnishing an excellent domestic system, but also a convenient motive power to a large number of manufacturing establishments of moderate size, either by means of turbine-wheels or hydraulic engines. The enterprise proved so successful in this respect that the entire available supply was taken up within a brief period, the demand for power proving to be largely in excess of the capacity of the works. Two enterprising manufacturers, M. Roulet, lapidary, and M. Bourgeois, watch-case manufacturer, who occupied the same building and who had been obliged to supplement their water power by means of gas and steam engines, determined to make a trial of electrical transmission.

The volume of available water at the point where the turbines are placed is about 1,500 litres (375 gallons) per second, and the fall is about 54 metres (177 ft.). The Girard turbine which is employed is however capable of utilizing only 400 litres under a head of 46 metres, thus giving about 180 effective h. p. The water is led to the turbine by a tunnel cut through the rock 2 m. (6 ft. 6 in.) high by 1.5 m. (4 ft. 11 in.) wide. The turbine is belted to the dynamo electric generator instead of being directly attached. The dynamo machines used are of the Thury pattern, which is a modified form of Gramme. The distance between the generator and the motor is 1250 m. (about 4,100 ft). The amount of power required by the two manufactories varies from 6 to 18 h. p. One of these is a rolling mill for preparing silver plates for watch cases, and necessarily varies considerably in its requirements in this respect. The other, in which watch-jewels are cut and drilled, requires the utmost possible uniformity of speed. After several experiments a compound winding for the dynamos was adopted, by which a constant speed may be maintained without reference to the amount of power required. The conductors employed are two copper wires of 7 mm. diameter (No. 1, B & S. gauge) suspended in the air upon posts and tied to porcelain insulators in the usual manner of a telegraph line. The generator and the motor are of the same size, both being of the type designated by the makers as H 2. The generator makes 500 revolutions per minute and gives an E. M. F. of 350 volts. The motor makes 400 revolutions, under a potential averaging about 300 volts.

The speed of the motor is controlled by varying the resistance of the line conductor. A box of graduated resistance coils formed of brass wire, is provided with a rotating contact-arm and a series of contact terminals. The arm is operated by a pinion movement communicated through an endless screw, which effectually prevents the resistance from being varied so suddenly as to endanger the coils of the machines. It requires at least 20 seconds to withdraw the entire amount of resistance from the circuit by the screw movement, which gives the motor ample time to work up to its maximum speed after starting. Ordinarily a portion of this adjustable resistance is left in the circuit, for convenience in adjusting the speed of the motor. This provision is necessary, because the proper speed of the machinery for drilling watch-jewels must bear a certain relation to the temperature of the room in which the work is done.

It has been found necessary to furnish the line with lighting arresters at both ends, the locality having proved to be unusually subject to atmospheric electrical disturbances.

This admirable practical application has now been in operation for more than 7 months; occasional interruptions took place at first, which were mainly due to a lack of experience in properly adjusting the commutator brushes, but since the employés have become familiar with the machines these difficulties have entirely disappeared. Careful tests have been made to determine the percentage of power utilized; the results of which are promised in full in a future communication. It is unofficially stated that an efficiency of 70 per cent. has been reached under the most favorable conditions.

This installation is especially interesting as it establishes the entire practicability of the industrial application of a considerable force at a considerable distance from its source, and demonstrates conclusively that the work may be successfully accomplished on a much larger scale if required. The work of the installation was designed and executed by the establishment of Neuron & Cuenod of Geneva.

ELECTRICITY FOR CITY RAILWAYS.

A LETTER from Professor Moses G. Farmer to Cyrus W. Field, recently published in the *Mail and Express*, contains some interesting calculations as to the saving that could be effected on the Second avenue elevated railway by the substitution of electric motors for the steam engines now in use there.

I assume, says Mr. Farmer, that a stationary plant can be erected somewhere near the middle of the line, not far from Sixty-third street, this plant to consist of one or more stationary steam engines of the best type, capable of developing one h. p. by the combustion of $1\frac{3}{4}$ pounds of coal per hour per h. p. by the use of such coal as does not cost over $2 50 per ton of 2,240 pounds.

I assume that there are in use on this line 20 locomotives of 110 h. p. each at the busiest hour of the day, and that each locomotive consumes—per h. p. per hour—5 pounds of coal that cost $4 per ton of 2,240 pounds.

I assume that the rails now in use are of steel and weigh 70 pounds per yard, and that a central steel rail of 70 pounds per yard will be laid for the purpose of conveying the electric current to the motors.

I assume that 1 mile of such steel rail will offer about $\frac{1}{100}$ of an ohm's resistance, and that the aggregate internal resistance of the dynamos concerned in producing the current will not exceed $\frac{1}{100}$ of an ohm.

I assume that from this central station sufficient current will be supplied to both tracks to energize at the same instant all of the 20 electric locomotives, no matter on what part of the tracks these motors may be situated.

I assume that 1 h. p. is the equivalent of 746 ampère-volts, and that $20 \times 110 \times 746 = 1,641,200$ ampère-volts, in the aggregate, reach these motors.

I assume that such dynamos can be constructed as shall convert 90 per cent. of the mechanical power applied to them into current electricity, and I also assume that such electric motors can be constructed and used as shall convert 90 per cent. of the electricity which they receive into power used to draw the trains which are attached to them.

I assume the Second avenue railway to be $6\frac{1}{2}$ miles in length.

With these assumptions I have calculated the following tables:

TABLE I.

Volts.	Present power.	Future power.
500	2,200	3,369
1,000	2,200	2,879
1,500	2,200	2,787
2,000	2,200	2,757

TABLE II.

Volts.	Present coal.	Future coal.	Saving per hour.
500	11,000	5,896	5,104
1,000	11,000	5,039	5,961
1,500	11,000	4,889	6,111
2,000	11,000	4,825	6,175

TABLE III.

Volts.	Present cost.	Future cost.	Saving per hour.
500	$19 65	$6 58	$13 07
1,000	19 65	5 62	14 03
1,500	19 65	5 46	14 19
2,000	19 65	5 38	14 27

Table 1, column 1, contains the electromotive force developed by dynamos at the central station; column 2 contains the h. p. required by the 20 locomotives; column 3 contains the h. p. that must be used at the central station in order to deliver at the electric locomotives the equivalent of 2,200 h. p.

Table 2, column 1, contains the electromotive force, as in the first table; column 2 contains the hourly consumption of coal by the 20 locomotives now in use—5 pounds per hour per h. p.; column 3 contains the amount of coal consumed by the stationary engine that develops 1 h. p. by the combustion of $1\frac{3}{4}$ pounds of coal per hour; column 4 shows the saving in pounds of coal per hour made by substituting the better engine, the dynamo, the electric motor and the rail circuit.

Table 3 shows the hourly saving in dollars and cents by the substitution of electricity thus applied for the coal now used in the locomotives.

It will be seen from this last table that the lower and safer electromotive force of 500 volts is only about 9 per cent. more expensive than the 4 times as great 2,000 volts, and about 7 per cent. more expensive than 1,000 volts.

I must reserve for another letter my conclusions regarding what would be the savings resulting from the use of electricity on the Third avenue line, as I wish to obtain some further information as to frequency of trains.

JUSTICE AT LAST.

AFTER long and weary waiting, after four years of contest, and an expenditure of money which would have ruined most litigants, a decree has been ordered for the Bell Telephone Co. in its suit against the People's Telephone Co., representing the alleged inventions of Drawbaugh, and the injunction against the People's company is now made perpetual, with the right of appeal, of course, to the Supreme Court, which will doubtless be taken. But, for all practical purposes in the near future, the decision is final, since it will take a number of years for the Supreme Court to reach the case, and in the meantime the defendants are powerless.

As yet we have not seen the full text of the decision, but enough of it has, at the present writing, been made public to show that the judge, in a large measure, bases his opinion upon the inherent improbability of the rightfulness of the claims of Drawbaugh, who, according to his own story, calmly stood by after he had made these important and well-nigh invaluable inventions, and without a word of protest permitted another to reap the glory and the reward. This the judge considers fatal, despite the great mass of evidence adduced in support of the Drawbaugh claims.

We have more than once, while this important suit has been pending, expressed our dislike and disapproval of "trial by newspaper," and certainly now that the appointed tribunal has rendered a learned and exhaustive decision, any judgment that we or any other newspaper might render would be highly unimportant and unnecessary. But we may be permitted to say, now that the case is settled and an award has been made, that we have steadily been of the opinion that the Drawbaugh claims were founded upon a conspiracy to rob men of their just rights under the patent laws. We are very far from expressing the opinion that all or any considerable number of those who have been prominently connected with the enterprise were either cognizant of or parties to the conspiracy. On the contrary, we are firmly convinced that it was part of the scheme to get honorable and innocent men honestly interested, so as to give character and respectability to an enterprise which had none of its own. And we further believe, now that the case has been decided in favor of the Bell company, that the conspiracy, no longer held together by the cohesive power of prospective plunder, will fall to pieces, and that we shall yet see the inside of one of the greatest pieces of rascality ever concocted, to the disgrace of the few who devised it, and the chagrin and mortification of very many more who were honestly misled

Digitized by Google

into believing the story to be genuine and staking their money on the result.

Believing this, and feeling that nothing more than exact justice has been done—and who, having read even a synopsis of the evidence, could doubt what the result would be? —we feel like offering our congratulations to the Bell company, and to all who, directly and indirectly, will be benefited by the fact that an end has come to the long suspense. The sub-companies, operating under licenses from the parent company, will take new courage, their work will be extended and enlarged, the number of outstanding telephones will increase, and the whole industry will take a new start.

Of all the men who will receive congratulations no one deserves them more than Mr. Storrow, now taking a well-earned rest in Europe. We venture to say that, for sustained effort, for intimate knowledge of the subject in hand, for exact accuracy in the plain, straightforward recital of facts, their bearing upon one another, and the deductions to be drawn from them, his argument stands alone in the long list of pleas that have been made before the United States Court in patent causes. It was the justice of the company's cause which won the case, but it was the way in which it was put by Mr. Storrow that made its justice apparent.—*Electrical Review.*

MEASURING ELECTRIC CURRENTS.

Lord Rayleigh has suggested the application of Faraday's discovery of the rotation of the plane of polarized light by an electric current as a means of measuring the current. Mr. J. E. H. Gordon found that the reversal of a current of 4 ampères circulating 1,000 times round a column of bisulphide of carbon through which the polarized ray passed, produced a rotation of the plane of polarization of the ray of about $7\frac{1}{2}°$. With heavy glass, which is more suitable for measuring purposes, the rotation is somewhat greater. The method does not seem very promising, but in Lord Rayleigh's hands something may be made of it. It has the advantage of requiring no springs or gravity indicators, the ray of light serving this purpose. One drawback exists in the depolarizing properties of heavy glass. A more useful, if less novel, method of measuring currents by means of the ordinary apparatus is also given by Lord Rayleigh. A standard cell is connected through a high resistance, such as a set of resistance slides, and 2 points in the slide are found which have the same difference of potential on 2 points of a strip of german silver through which the current to be measured is passed. The equality of potentials is found by a galvanometer in circuit which gives no deflection where the 2 points are found. Knowing the difference of potentials on the slides (it is equal to the electromotive force of the cell x, the resistance between the 2 points on the slide divide the whole resistance of the slides), and the resistance between the 2 points on the german silver sheet, the strength of current is easily found by Ohm's law. It is equal to the above difference of potentials divided by the resistance between the 2 balancing points on the slide. This method is well known; but the use of a german silver strip with lugs or projections on it at a given resistance apart to serve for the points of connection in the balance, is a new modification.

THE PROBLEM OF POWER.

A prominent engineer is reported by the New York *Tribune* as saying: "Scientific invention runs in grooves. Electricity has unquestionably been the great development of the past 20 years. While nothing is impossible, I think the limit of electrical invention has been reached. Applications of the inventions already made are engrossing attention. In that direction the great problem is power. It is a singular fact that since the discovery of steam and its application as a motive power there has been no great invention in steam. Now that inventors are applying themselves to extending the electrical inventions, they find cheaper motors necessary. You will see that inventive genius will improve steam making by revolutions as wonderful as any that have taken place in other branches of scientific investigation. What discoveries will be made I cannot predict, but I believe the next step in scientific progress will be in that direction."

LITERATURE.

REVIEWS.

Bell's Electric Speaking Telephone: Its invention, construction, application, modification and history. By George B. Prescott. With 380 illustrations. New York: D. Appleton & Co., 1884.

Dynamo-Electricity: Its generation, application, transmission, storage and measurement. By George B. Prescott. With 545 illustrations. New York: D. Appleton & Co., 1884.

The introduction of the speaking telephone for commercial and business purposes, which had begun to be quite general in this country in the early part of the year 1878, excited in the mind of the average citizen an unprecedented interest in the phenomena of electricity, and in the details of some of its more recent, and at that date surprising applications to industrial uses, and it created an immediate demand for literature relating to the subject, which has not merely continued, but has ever since continued to increase. In the year mentioned Mr. Prescott issued a work under the title of the *Speaking Telephone and other Novelties*, which was, we believe, the first attempt to treat these subjects in detail, and in a manner adapted to the popular comprehension. The general favor with which this work was received led to its reissue with material changes and additions some two years later. In the new edition, a considerable amount of space was devoted to the subject of electric lighting, so far as it had at that time been practically developed. The growth and evolution of the industrial applications of electricity has, however, been so rapid that Mr. Prescott has now found it necessary to depart from the plan of his original work, and to divide its subject matter into two distinct volumes, one of which is devoted to the telephone and the other to the general subject of dynamic electricity, of which electric illumination is at present by far the most important practical application.

The present work on the telephone is evidently designed to be an exhaustive one, and it certainly embraces a far greater amount of information relating to all branches of the subject than any other one which has yet appeared. A portion, perhaps one-third, of the present volume, contains substantially the same matter as the edition of 1880, although this has been somewhat revised, as the progress of the art seemed to render necessary. The remaining portion of the work is for the most part entirely new.

We find here given, for the first time, detailed and fully illustrated descriptions of the principal telephone exchange systems in practical use. The account of the central telephone system in Paris is especially complete, and is moreover exceedingly interesting. The leading systems which are or have been in use in the United States are described at length, especially the so-called "Chinnock" and "Law" systems which are employed in the telephone exchanges of New York city. One long chapter is entirely devoted to descriptions, for the most part well illustrated, of the more prominent of the innumerable modifications, improvements and mis-improvements which have been made by others upon the original invention of Bell. Among these, however, the Blake transmitter is passed over with a description much more meagre than would seem to be warranted by its unquestionable merit as an invention, and the enormous extent to which it has been adopted and used in connection with the fundamental invention of Bell. By some unaccountable oversight, no mention is made of the Hunning transmitter, which has developed such a surprising capacity for the transmission of articulate speech to great distances, and which has, we believe, been definitely adopted by the American Bell Telephone Co. for its long lines, such for instance as that between Boston and New York—a distance, as the wire runs, of perhaps 275 miles.

The space which has been devoted to a description of some of the abortive conceptions of Edison having no particular relation to the subject in hand, such, for example, as the "aerophone," the "harmonic engine," the "megaphone" and the "phonometer," might perhaps have been utilized to better advantage in giving some account of the individual-call system, one of the ingenious outgrowths of the telephone exchange which has found

Digitized by Google

a not inconsiderable application in practice, especially in sparsely settled localities.

Another chapter is devoted to the history of the invention of the speaking telephone, embodying a considerable amount of interesting information not hitherto accessible to the general public. It contains, among other things, the substance of the able and exhaustive report of the Examiner of Interferences in the United States Patent Office, in which the entire history of the invention, as developed by the several claimants, is set forth with great minuteness. While we entirely agree with the conclusion of the author that Bell was unquestionably an original inventor as well as legally the *first* inventor of the speaking telephone, and that it is to him and those associated with him to whom the world is indebted for the benefits of this invention, yet we feel compelled to dissent from the somewhat summary manner in which he dismisses the claims of Elisha Gray. The evidence in support of Gray's claim is perhaps sufficiently well presented by Mr. Prescott, the facts as between Bell and Gray appearing to be simply these: Prior to 1875 Bell had dimly conceived the possibility of transmitting and reproducing articulate speech by electricity. On June 2d, 1875, he accidentally noticed that very slight vibrations of a thin armature in front of a magnet induced magneto-electric currents capable of appreciably affecting a receiving instrument—a fact which gave him the key to the telephonic problem. Under his direction, his assistant Watson immediately constructed a pair of membrane instruments, which were tried in June and July, 1875, but with exceedingly unsatisfactory results, although in the light of present knowledge it is plain enough that articulate speech might have been, and probably in fact was, transmitted by the apparatus as then used, although the ear of the listener, being as yet untrained, was not able to detect it under the conditions of the experiment. Nevertheless, in the latter part of 1875 and the early part of 1876, Bell prepared a specification which he filed on February 14, 1876. This document contained a drawing and description of an apparatus which was substantially that used in the experiment of June, 1875. It appears, however, that until after the time of the issue of this patent, March 7, 1875, the invention was not successfully reduced to practice.

The so-called lover's telegraph, a street-vender's toy consisting of two membranes united by a string, suggested to Gray, in December, 1875, a definite idea of the true principle of the speaking telephone. He did not disclose this conception to others, nor reduce it to form until February 11th, 1876, when he made a sketch from which a caveat was prepared, which by one of these remarkable coincidences which are of such frequent occurrence in the history of invention, was filed in the Patent Office on the same day as Bell's application, and only a few hours later. It seems well established, however, that until after this date neither Bell nor Gray had any definite knowledge of the character of each other's work. The caveat of Gray contains a far more complete exposition of the principle of the transmission of articulate sounds than the patent of Bell, and it seems certain that at that date, he was farther advanced upon the right road than his competitor. For some reason, however, he was dilatory both in reducing his invention to practice and in filing his application for a patent, and thus it happened that Bell, who had been the earliest to definitely conceive the invention, was also the first to obtain a patent, and the first to reduce it to actual practice, which he appears to have done on the 8th of May, 1876. Singularly enough, it has been shown by the evidence taken in the Drawbaugh case, that the first transmission of speech was accomplished by Bell with an instrument substantially the same as that described in Gray's caveat, and entirely unlike that shown in Bell's own patent. Without, therefore, detracting in the least from the claims of Professor Bell, it would seem that Mr. Prescott has scarcely given Gray his due in his summary of the history of the invention.

Mr. Prescott gives a curious bit of the inside history of the controversy between the Western Union Telegraph Company and the Bell Telephone Company, and of the negotiations which led to the existing alliance between these organizations. He says:

> The history of this controversy shows how great results sometimes follow insignificant causes. In the summer of 1875 Mr. Bell asked permission of the Western Union Telegraph Co. to conduct experiments in the office of their electrician at New York. This was granted; but shortly after Mr. Bell began his experiments there, Mr. Orton, the president of the company, learned that Mr. Gardiner G. Hubbard, who was personally obnoxious to him, was pecuniarily interested in Mr. Bell's inventions, and immediately directed that the permission to conduct his experiments should be withdrawn. After Mr. Bell had brought his invention before the public, and was endeavoring to perfect it by experimenting over actual telegraph lines, orders were given to exclude him from the Western Union wires. In spite of these orders, however, telephone experiments were conducted over them; but for a long time the results, while regarded with interest, were looked upon as possessing little practical value, and it was not until the summer of 1877 that the progress of Mr. Bell's invention was deemed to have arrived at such a state of efficiency as to threaten to be a serious competitor of the telegraph. At this juncture, August, 1877, Mr. Frank L. Pope, the electrical expert of the Western Union Telegraph Co., saw and talked through a speaking telephone in Boston for the first time, and soon after mentioned the fact to Mr. Orton, who said: "I have been looking into this matter of the telephone somewhat, and regard it as a matter likely to be of considerable future importance. If this proves to be the case, it is very necessary that we should have the right to use it; therefore I wish you to make a careful and thorough investigation of the whole subject, and ascertain what are the fundamental principles of the invention, and what inventions or patents it will be desirable or necessary for us to acquire the control of, in order to be able to use the invention in connection with our business."

The result of the expert's report was that the right to Gray's inventions was acquired, in addition to those of Edison w ch the company already controlled, and the manufacture and leasing of telephones was commenced through a sub-company known as the Gold and Stock Telegraph Company. An action for infringement was at once instituted by the Bell company, which was in progress during the summer of 1879. Mr. Prescott says:

> After a very vigorous defence had been made by the Gold and Stock Telegraph Co., and testimony at great length and great expense had been taken in support of the answer, and the testimony was substantially closed on both sides, Mr. Gifford (the leading counsel for the Western Union) became convinced that Bell was the first inventor of the telephone, and that his patent had been infringed by the use of the telephones in which carbon transmitters and microphones were elements, and that none of the defences which had been set up could prevail against him, and advised the company to that effect, and suggested that the best policy for them was to make some settlement with the Bell company.
>
> For the purpose of effecting such a settlement, the position of the Gold and Stock company was very strong. They controlled, through the Western Union Telegraph Co., the celebrated Page patent, which covered the induction coil used in the transmitters of the telephone, and was of great importance to them, and which the Bell company were using.
>
> Under Mr. Gifford's advice a negotiation was opened with the Bell company on the basis of the claims which the Western Union Telegraph Co. made, that the telephone used by the Bell company was an infringement of the patents and applications for patents owned or controlled by the Western Union Telegraph Co. Mr. Gifford met Mr. Chauncey Smith, counsel for the Bell Telephone Co., by arrangement, at the White Mountains, where they remained for a week in negotiation. Mr. Gifford opened the negotiations by admitting that Bell's patents were valid, and that the Gold and Stock company infringed them, and these questions formed no part of any discussion between them, but claimed, on the part of the Gold and Stock company, in view of their patents, that all the patents should be put together, and that they should have one half in the joint property. This claim was refused by Mr. Smith, and the negotiations failed at that time. After Mr. Gifford's return, Mr. Prescott, the vice president of the Gold and Stock Telegraph Co., then in charge, had an interview with Mr. Causten Browne, who coincided in Mr. Gifford's views, and said that the Court would undoubtedly sustain the Bell patent of March 7, 1876, the fifth claim of which, viz., "The method of, and apparatus for, transmitting vocal or other sounds telegraphically, as herein described, by causing electrical undulations, similar in form to the vibrations of the air accompanying the said vocal or other sounds, substantially as set forth," covered all electric speaking telephones in use. Upon the receipt of this advice, negotiations were immediately reopened with the Bell company, and soon resulted in a contract, in which, instead of the Gold and Stock company and its associates getting one half of the joint property for the inventions which they contributed, and which were essential for the satisfactory operation of the best telephone system, they got only 20 per cent. of the earnings, and agreed to go out of the business and never to make use of any telephones, excepting such as they should acquire the right to use from the Bell company and pay them the market price for, the same as other people have to do. They transferred to the Bell company their exchanges for cost, and sold them their instruments at 25 per cent. less than cost, and thus ended the first attack on Mr. Bell's invention of the electric speaking telephone.

The reader will find the history of the claims of various rival claimants to the invention, or to some portion of it, including McDonough, Dolbear, Voelker, Edison, Drawbaugh, etc., given at length, with copious extracts from the opinion of the Examiner of Interferences in which he passed upon the evidence presented in behalf of each.

In an appendix to the work, the decision of Judge Lowell in the case of the *American Bell Telephone Co.* v. *Spencer*, and that of Judge Gray in *American Bell Telephone Co.* v. *Dolbear*, are given in full, which will be found convenient for reference.

The mechanical execution of the book is excellent, and the illustrations are not only profuse, but are far more artistically executed than has of late been usual in works of this description.

We find that we have scarcely left ourselves space for an adequate notice of Mr. Prescott's work on dynamo electricity, which is for the most part a descriptive one, although a considerable amount of historical information is given. The first two chapters of the work are substantially unchanged from the edition of 1880, and give a sufficiently satisfactory exposition of the subject as it existed at that date. It is a question, however, whether it would not have been a better plan either to have omitted these chapters, or to have placed them by themselves in an appendix, as they really contain but little material which is of value in the present state of the art. These chapters, however, form but a small portion of the work; the remainder contains an amount of useful information upon the general subject which it would perhaps be difficult to find elsewhere within such moderate compass.

Something like 100 pages are devoted to an exceedingly well illustrated description of the Edison system of electric lighting, including not only the generators, lamps, conductors and fixtures, but the process of manufacture as well. The account of the central station lighting system in New York city is particularly complete, and will be found of much interest. It would seem, however, that the information might have been brought down to a later date, for no mention is made by Mr. Prescott of the improved Edison-Hopkinson dynamo, which we believe is now used by Edison in lieu of the older forms, nor of the ingenious three wire system of distribution which has been in operation in Brockton, Mass., and elsewhere, for a year or more. Mr. Prescott gives credit, and we believe properly, to Edison as the first to adequately appreciate the economical advantages of an exceedingly low internal resistance in the generator. He also attributes to him the invention of the sectional armature made up of thin discs of iron, whereby the injurious eddy currents are broken up. This, however, is a mistake; Mr. Weston undoubtedly constructed an armature in this manner at least as early as 1874, and described it in an application for a patent filed by him on June

Digitized by Google

4th, 1878, which was before Edison took up the question of dynamo machines at all. The extraordinary size and partial saturation of the field magnet in the earlier forms of the Edison dynamo are also mentioned as advantageous, but experience has demonstrated that this is not the case, and accordingly the field magnets of the later machines have been largely reduced in weight, while their efficiency has at least not been diminished by the change. The Maxim, Swan, Weston, Bernstein and Lane-Fox incandescent lamps are sufficiently well described, and the reports of the tests of these and other incandescent lamps at the Paris Exposition of 1881, with the tabulated results, are given at length.

Turning to the chapter on arc-lamps and regulators, the reader will find described and illustrated almost every one which has attained any prominence whatever. The author has very properly paid particular attention to the descriptions of the lamps principally in use in this country, as being of more importance and interest than others.

In the chapter on dynamo-electric generators, the principle of the machine is first set forth, and this explanation is followed by a description of the principal inventions of this class now in use throughout the world. We note particularly an illustrated account of Hjorth's machine, which was patented in England in 1855, and which in fact embodied the great discovery of the mutual interaction of the armature and field which constitutes the fundamental principle of the modern dynamo. The portion of this chapter which relates to the work of Mr. Weston and the evolution of the remarkably efficient dynamo machine now so well known by his name, is noticeable for its clearness and completeness. We find here for the first time an adequate description of Weston's self-regulating dynamo, of which the electromotive force remains constant under all variations in the resistance and the external work, a machine which excited the utmost interest and admiration among the scientific visitors at the recent Philadelphia exhibition.

A brief account is given of the more prominent of the electric motors which are of interest either from a historical or a practical point of view, together with a succinct account of the different electric railway systems which have thus far been brought forward.

The final chapter, which treats of electrical measurement, and especially of the measurement of powerful currents, is deserving of unqualified commendation. We know of no treatise which will bear comparison with it, either in its masterly exposition of the principles upon which the methods of measurement are founded, or in the clear and satisfactory manner in which these methods are explained so as to render them available to the practical electrician and experimenter. Almost every one of the recently invented instruments adapted to this class of measurements is fully described and illustrated, and its excellencies and defects pointed out. The adaptation of particular instruments to particular methods of testing are also suggested, and the sources of probable error indicated. To the student, the experimenter and the electrical engineer, this portion of the work will be simply invaluable, and Mr. Prescott could confer no greater favor upon the profession than to republish it separately in a compact form convenient for the pocket and the laboratory table.

Stationary Steam Engines, especially as adapted to electric lighting purposes. By ROBERT H. THURSTON, A. M., C. E. New York: John Wiley & Sons, 1884.

THE electrical engineer of the present day who aspires to a more than superficial knowledge of the higher branches of his profession, must include the subject of mechanical engineering—at least so far as it has to do with steam-engines and the use of steam power – among his subjects of study. The development of the steam-engine within the past few years, due mainly to the exacting conditions as to efficiency, regulation and smooth action at high speeds arising from the requirements of electric lighting, has been very great. At the request of the editor of this journal, Professor Thurston prepared, some time since, a series of papers containing a systematic outline of the evolution of the now accepted type of high-speed engine for electric lighting plants, in such form that the causes of the various modifications of construction and operation which have resulted therefrom might be readily understood. Many of our present readers are familiar with these papers, which appeared in our columns during a portion of the years 1883 and 1884, and will doubtless be pleased to know that they have been reprinted, with corrections and some additions, in a neat little volume of 187 pages. Professor Thurston, who is one of the best of authorities on this subject, has studied his subject in connection with descriptions and discussions of representative standard types of engines. The electric light engineer will here find set forth the distinctive characteristics of nearly every one of the modern stationary engines which have proved themselves especially adapted to his work, and will find Professor Thurston's analysis of the subject of great value in making an intelligent choice for the particular purpose which he may have in hand. The book is handsomely printed and well illustrated, and while indispensable to every electric light engineer, is by no means without value in other departments of industry.

Map and Plan Drawing. By C. COOPER KING, Lieutenant Royal Marine Artillery. New York: Cassell, Petter and Galpin.

A FEW years since a treatise on map and plan drawing would have had no possible relation to the ordinary work of the electrical engineer. At the present rate of progress, however, he will soon be called upon, among other things, to lay out electric railways and hydraulic works to provide for the transmission of power by electricity from inaccessible places where it is not wanted, to accessible places where it is wanted In this class of work, a knowledge of the subject of Lieutenant King's little work will be found to be of material value. Although the subject is treated mainly from a military point of view, the instructions are equally applicable to the work of the civil engineer. We have seen no treatise so well adapted as this to serve the purpose of the busy man who desires to obtain the greatest possible knowledge of the subject with the least expenditure of time and trouble. The volume is in handy pocket form, and may be carried about and studied at leisure.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents. Anonymous communications cannot be noticed.

The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.

In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.

Sketches and drawings for illustrations should be on separate pieces of paper.

All communications should be addressed EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

THE EDISON ELECTRIC LIGHTING SYSTEMS IN THE UNITED STATES.

[28]—In reply to your letter of the 8th inst., I beg to state that the total number of incandescent lamps in the United States at the present time in isolated plants is 75,000, and in central stations 34,800, making a total of 110,000 lamps in all, within the United States, which would represent 14,000 h. p. The most important part of our business is that of licensing and organization of local companies for central stations, where the current is furnished to the consumer from a central point, and charged by a meter according to the exact quantity of light consumed, at prices not exceeding the ruling prices of gas, and leaving a profit to the sub-company. This has never been accomplished either electrically or commercially by any other system of electric lighting in the world. In the city of New York, we have 600 customers, using 13,000 lamps all lighted from 1 station, and we have applications from 100 customers more than we are able to supply with our present capacity. That station is now earning a very handsome profit, and has been running day and night for more than 2 years. Very truly yours, F. S. HASTINGS,
Secretary and Treasurer.

The Edison Company for Isolated Lighting,
65 5th Ave., New York, December 17.

[The above information was kindly furnished in response to a request, and we are sure will be of interest to our readers.—EDITOR.]

QUESTIONS AND ANSWERS.

[49.]—**Raising and Lowering Arc Lamps.**—T. D. R., referring to our Chicago letter, page 247, Vol. III, wishes to know if a successful device for this purpose would be a paying investment, also if required in incandescent lighting. **Ans.** This is one of those cases of detail, which even if successfully treated and appreciated would probably not be considered a *valuable* invention. It is unnecessary in incandescent systems.

[50.]—**Battery for Incandescent Lamp.**—I. B. La M., Montreal, asks for information regarding a battery sufficiently strong to operate a small incandescent lamp experimentally. **Ans.** See replies to questions 10 and 11, vol. III, page 67.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Tribulations of the Pooling Telegraph Companies.—Anxious Telegraphers.—Journalistic Enterprise.—Subterranean Progress.—Electric Light Competition.—The Commercial Cable Co.—The Manhattan Kiosk Co.—Automatic Protectors Wanted for City Wires.

SINCE the retirement of the Baltimore and Ohio Telegraph Co. from the tri-partite agreement, the Postal and the Bankers and Merchants' companies have been working together in harmony, so far as could be observed by the public. It is generally understood, however, that behind the scenes there have been symptoms of a final rupture ever since the pool was formed. All concerned appear to be in good spirits over the dissolution. It is well known that these separate organizations cannot pay expenses on the basis of the present tariff. It is hardly probable that any solvent company will care to assume the bonded obligations of the Bankers and Merchants' Co., especially during the present commercial depression.

The reported action of the Western Union Telegraph Company in discontinuing its practice of paying extra for overtime, in different parts of the country, has created considerable anxiety in this city, where no such notice was posted. This is believed to be a repetition of the old device to first feel the pulse of the fraternity at distant points, while not admitting at headquarters that there is any truth in the reports. While there is no immediate apprehension of a strike, it being well understood that this is the dull season of the year in the northern states, advantage is being taken of the existing excitement by the operators to perfect an organization which will be ready for any future emergency.

One of those great feats of modern journalism, which can be fairly appreciated only by those familiar with the work, was the publication of the proposed Spanish treaty by the *New York Times*, in advance of its official promulgation through the regular channels. It was telegraphed from Madrid in Spanish, and translated in this city. It contained over 6,000 words upon which the telegraph tolls were $4,400. It is such exhibitions of enterprise as this on the part of a single newspaper, which seem to indicate that journalism has outgrown the antiquated machinery of the Associated Press.

The New York and New Jersey Telephone Co. has inaugurated the subterranean era in Brooklyn, and began work in Joralemon street, December 10th. This company will use the Callender and the Patterson cables. In this city the Edison, Patterson and Brooks systems are to be used, with a view to eventually determining which is practically the best and most economical.

The close competition between the rival electric lighting companies is aptly illustrated by the proposals received for establishing an electric light plant on Ward's Island. The Board of Estimate and Apportionment, granted $15,000 for the purpose. The Edison company's bid was $13,500; the Sawyer-Man company's $14,078, less $500 if certain fuel be supplied for 30 days, and the Brush-Swan company's $13,735. The successful bidder will be compelled to furnish two bonds of $10,000 each, and guarantee the working of the plant for six months. According to the specifications 876 burners will be used on the island. It is expected that better and purer air will be obtained in the hospitals by using electricity instead of gas.

The Commercial Cable Co. has completed the laying of its subterranean connection with the office at 21 Wall street, by drawing a cable through an iron pipe laid under the pavement, from the East River Bridge via Water and Wall streets. Cable telegraphy is a novelty in this city, and the syphon recorder has been placed where it is easily viewed from the sidewalk through the plate-glass front, and the curious may readily satisfy their desire to see the mechanism without violating the secrecy of the establishment. The broken ocean cable was spliced December 19th, and the company opened December 23d for regular business. It has been thoroughly advertised.; has a good business location; a most competent and experienced manager, and will probably secure a fair share of patronage, if the alleged antipathy to Jay Gould has any foundation in fact.

There is considerable curiosity as to the real intentions of the Manhattan Kiosk Co., which is making strenuous efforts to secure from the city authorities, permission to erect newstands or kiosks at various points in the streets. They are to be fitted up with police, fire-alarm and district telegraph communication, and possibly lighted by electricity. Considerable opposition has been awakened by the owners of existing street privileges for various huckstering purposes, and the movement certainly has the outward appearance of what may be as offensive a monopoly on the surface, as the elevated railroad news company is above ground. The scheme has been buried for the present, but will doubtless be resuscitated eventually.

In consequence of the damage to the police telegraph instruments caused from time to time by the crossing of the electric light and the city wires, application has been made by Superintendent Crowley for authority to use some system of automatic protection, which will obviate such difficulties in future.

NEW YORK, Dec. 26, 1884.

NEW ORLEANS.

The World's Industrial and Cotton Centennial Exposition.—The Provisions for Steam Power.—A Glance at Some of the Leading Features.—The Distribution of Time.—The First Telegram from Washington to Baltimore.—How the Machinery Was Not Started by Electricity.—The Opening Ceremonies.

NEW ORLEANS, famous as it is for its holidays and carnivals, has never yet seen such a day as this. Business in general was suspended, public buildings, stores and dwellings profusely decorated, while the people turned out in full to attend the opening of the "greatest exposition the world has ever seen."

Advertised as it has been, everybody knows of its great main building—the largest ever built, its roof covering 33 acres of exhibits from all quarters of the globe. Vast as are these proportions, they have proven entirely inadequate. Forty-five hundred exhibitors cannot all be satisfied. Twice has Machinery Hall (part of the main building) been enlarged by extensions. The Director-General stated to the Board of Management that if they would roof the entire park—247 acres—he could fill it with exhibits in sixty days!

Boilers aggregating 5,200 h. p. are situated a safe distance from the building, and furnish steam through a 30-inch pipe to 22 engines of various sizes, of a total of 4,500 h. p. Of this, 1,600 h. p. are needed to drive the electric plant used in lighting the buildings and grounds. Eleven thousand feet of shafting will drive machines of almost all known kinds. Worthington pumps distribute 3,000,000 gallons of water daily through a comprehensive system of pipes. Fifty-two hydrants are situated judiciously in the main building as a safeguard against fire.

Several systems of electric lighting will be shown conspicuously, contracts having been given the Edison, Brush, Jenney, Thomson-Houston and Leavitt-Mueller companies.

As with all other expositions, the exhibitors are coming in with a rush at the last moment; and although hundreds are ready, much still remains to be done, and probably several weeks will pass before all are installed. When, however, it is taken into consideration that every state and territory in the Union will be represented, and that 27 foreign governments applied for space, it is only to be wondered at that so much is already accomplished. To allow the delinquents a little more time, for a few days the gates will close at 4 P. M. After that the closing hour will usually be 10 o'clock.

Though by no means an electrical exhibition, the electrical features will be most striking. When we recall the Philadelphia Centennial, only eight years ago, and remember that an electric lamp was then almost a curiosity, we are amazed at the wonderful strides made since then. Here everywhere the numerous wires and lamps greet the eyes by day, and at night the vast buildings and extensive grounds will be in a blaze of glory. The great Corliss engine, the object of admiration of all who visited the Centennial, would prove incapable of driving the dynamos alone of this the greatest of all similar enterprises.

An astronomical clock in the main building will be connected electrically with the one in the Naval Observatory in Washington, and its time will be governed to the fraction of a second at noon daily. Time from this clock will be distributed electrically throughout the grounds and buildings. An electric railway is spoken of, but as yet no visible signs of it are apparent.

Among the Maryland contributions to the Exhibition is the first telegram sent from Washington to Baltimore. It was also at the Centennial, and for the benefit of those who have seen or will see it the following anecdote is related: In the spring of 1844, Morse, the inventor of the telegraph, proposed to make the first trial of his invention in a room in the Capitol at Washington. Several gentlemen were present, and when the question arose as to who should send the first message over the wires, one of them proposed that President Tyler should have that honor. No! no! no! was the rejoinder from every quarter. Mrs. Madison, the widow of our illustrious President, was next named. The yeas were then unanimous. She was sent for, and came down to the Capitol shortly afterwards. "Gentlemen," she said, on entering, "I understand you wished for my presence. What is it you expect of me?" Hon. John Wethered (now of Catonsville, Baltimore County), then a Member of Congress, who was present, informed her that she could send a message to Baltimore and receive an answer in 15 minutes. The expression of her face would have made a study for a painter as she rolled up her large blue eyes and said: "Can that be?" The message she sent was to Mrs. John Wethered, wife of ex-Congressman Wethered, and daughter of Philip E. Thomas, the first president and projector of the Baltimore and Ohio Railroad, and was as follows: "I send my love to Mrs. John Wethered."

Great regret was expressed upon all sides at the absence of President Arthur upon this occasion, as it was first expected that he in person would formally open the Exposition and set the engines in motion. However, the novelty of the opening being controlled by the President some 1,200 miles away, in a measure compensated for this disappointment. At the appointed time all available space in and about Music Hall (situated in the centre of

Digitized by Google

main building) was filled to its utmost capacity. Upon the orchestral platform were seated the officers and boards of the Exposition, commissioners of the states and foreign governments, the Governor and his staff, the Mayor and city officials of New Orleans, the orchestra and invited guests. Immediately in front was the Mexican band. In a conspicuous position was placed the telegraph instrument in direct communication with the President in Washington, and near it another, in charge of General Burke's little son, in connection with a bell placed upon the cylinder of the largest of the engines in Machinery Hall. The ceremonies were brief but imposing. Upon the appearance of Director-General Burke the air rang with cheers, which were repeated when Colonel Edmund Richardson, president of the Exposition, came forward and presented, by telegraph, the Exposition to President Arthur. The returning signal being received, Master Lyndsey Burke, in the presence of the great audience, repeated it to Consulting-Engineer Gilman, stationed at the engine, who at once opened the valve, and the big wheel commenced to move. Instantly five more engines were started, and hundreds of feet of shafting began their incessant revolutions. At that moment a large picture of President Arthur was swung in full view at the head of the platform, the Exposition was declared open, and, amidst cheers and music, the audience dispersed throughout the buildings and grounds. Thus favorably was this great enterprise inaugurated.

NEW ORLEANS, Dec. 16, 1884.

CHICAGO.

Explosive Subterranean Systems.—The Dorsett Underground Conduit.—Merchants Petitioning for Sidewalk Lighting Permits.—Growth of Electric Lighting During the Past Year.—The Western Union Underground System.—New Fire Alarm Plants.—Telephone Gossip.

A NEW phase in the underground question—the occasional blowing up of the gas in the conduits—seems to complicate, where in all conscience there was sufficient complexity before. It is evident that in large cities, where the "ground hog" ordinances are necessary. this new bugbear is playing mischief. Your Philadelphia correspondent, and since that, personal information from members of the Philadelphia fire department, show conclusively that no underground system which permits of the ingress of gases from the surrounding earth, is safe. The iron pipe in use by some of the telegraph companies in other places besides Philadelphia have proven faulty for similar reasons, and I am told the pipes laid during the summer and autumn of last year, in Chicago, have on more than one occasion blown up, seriously injuring one or more unfortunates who happened to stand in front of the gun.

Prof. J. P. Barrett, in an interview published in the *Tribune* a few days since, highly endorses the Dorsett conduit, and says, having "spent five years examining and testing devices for this purpose I finally recommended the use of the Dorsett system by the city."

The Dorsett system is that which is being laid for the electric light, telegraph and telephone wires, which, as has been previously stated, are all to be "sent below."

The conduit company has broken ground on Lasalle and Washington streets and is working southward at a fair rate of progress. The plan is to place proper "leading in" conveniences 20 to 25 feet apart, so that the wiring of two consecutive buildings can be readily accomplished, and the present system of spider-web or clothes-line decoration along the fronts of buildings be discontinued.

In the matter of lights upon the outside of buildings, there is continued difficulty. The electric light companies—or a portion of them—acting in concert for the first time I think, asked the opinion of corporation counsel Winston, relative to the prohibition of lights outside the building line of stores, etc. His opinion was adverse to the wishes of the gentlemen, and sustained the order, under Sec. 2,022 of the code, which, originally framed to cover the overhead wires of the telephone and telegraph companies, still included "electrical conductors," as among the "tabooed" abominations. So, at the last meeting of the city council a petition from sundry citizens was presented, asking permission to place outside lights at their several places of business. An order was also presented, and its passage asked, which will empower the sup't of city telegraph to grant such permits, subject to such regulations as he may deem proper. Their particular flurry just now is the desire to get lights out for the holiday trade, which seems to need a little extra boosting to bring it up to the average. The above communications were referred to the committee on fire and water—and Christmas is close at hand.

The forthcoming annual report of the electric light inspector to the sup't of city telegraph will show that there has been a very large increase in the number of electric light plants during the year, both arc and incandescent. One life only has been sacrificed in the city, and the peculiar circumstances of that occurence seem to throw a shadow of uncertainty on the cause of the death. Unfortunately the deceased was alone in the engine room at the time, and when found was lying upon his face, at least twelve feet from the back of the dynamo, with a shovel at his side. He had been at work with the shovel just before supper, and finishing before the rest of the employés, had returned to his work, alone. As he was a new man at the business, he had been repeatedly warned of the necessity of the utmost caution in handling the lamps and dynamo, and circumstances show that if he did come to his death by means of a current of electricity, it is quite certain that the accident arose from disregard of the frequent warnings he had received. *Per contra*, between May and November, 12 deaths are recorded from improper handling of gas.

The Western Union Co. has laid a four inch iron pipe from the office, corner of Washington and Lasalle streets to the city limits, at 39th street, in which to hide its wires. Electrician C. H. Summers, could give me no details as to the number, size or insulation of the wires which will be laid in this conduit. Information on these points it is presumed will emanate from headquarters in New York.

Mr. E. B. Chandler, Gen. Western Agent of the Gamewell Fire Alarm Telegraph Co., informs me that business for the past year has been prosperous, many new plants having been placed, and seven of those already in, considerably enlarged. Of the former he mentioned Algiers, La., Racine, Wis., Fargo, Dakota, and the town of Lake, in this county—the last being quite important as an adjunct to our city system, with which it joins territory. Among those extended are Milwaukee, St. Louis, Minneapolis, St. Paul, Oshkosh, Peoria and Denver. A temporary plant has also been placed in the New Orleans exhibition.

Telephone matters are moving along much in the same old way. Much satisfaction is evident among officers and stockholders of the Bell telephone adherents, at the decision in the Bell-Drawbaugh case. Central Union, which previous to the decision was only worth about 40 cents is now on the up grade, and has reached 70 and above. During the past year this stock has paid no dividends, but it is now very generally expected, that sometime in January a regular dividend will be handed to all the faithful, and that extra dividends will subsequently follow, to make up for those which have been passed. The Chicago company goes right along; apparently has known nothing of hard times, and the stockholders say they have no complaints to make on the paying quality of the scrip.

The Overland people are hard at work, but like Joe Bagstock, they are sly. A test was made a few days since between here and Milwaukee, which was said to be highly satisfactory. It looks now as if their promise of an exchange here on the first of January would hardly materialize, but—we shall see.

CHICAGO, Dec. 18, 1884.

SAN FRANCISCO.

The Question of Subterranean Lines.—Electric Lighting Maintained by Private Subscription.—Supposed Prospecting for the Postal Company's Extension.—Gold Medals Awarded in Return for Gratuitous Lighting.—Progress of Electric Lighting on the Coast.—Competing District Companies.—Active Telephone Management.—Reduction of Telegraphic Force.—An Electro-Political Candidate Defeated.

WHETHER our city fathers will force the various companies which operate lines in this city to run them underground is a question of much interest to shareholders and managers. If subterranean wires can be operated without creating unusual difficulties, their advent should be hailed with delight, particularly by the chief operators of the Western Union in this city, where the wet, thick fogs from the Pacific make Morse telegraphy almost impracticable for the time being, and allow very little margin in the box of a duplex. To the Telephone, Gold and Stock, and District companies it would work great pecuniary damage, and to some would be ruin. The Electric Light Co. is now sustained by private subscriptions, and it would be impossible to make it a pecuniary success on the basis of a subterranean plant; but as all flesh is grass, and grass is hay, it will be a new experience if some of the city fathers do not make hay while the electric sun shines, and allow the wires to remain as they are.

James Gamble is here, and his movements are watched with a great deal of suspicion and interest. It is surmised that he is laying plans toward building the Postal lines to the Missouri river, and that for this purpose he has entered into partnership with his brother-in-law and Mr. Booth, of Oakland, under the firm name of Coleman, Gamble & Booth. Whatever truth may be in the rumor remains to be demonstrated, but scarcely a better man could be selected for that purpose, as he knows every inch of this coast, as well as every business man of any prominence here. He would know where poles would have to be set with more than usual care, and other details which a stranger would pass over as trivial. Whether the advent of the Postal will be beneficial or otherwise to the skilled operator, certain it is its completion to this city is hopefully looked forward to by the fraternity.

Digitized by Google

At the annual fair held in this city the Brush and the Thomson-Houston companies alternated nights in lighting the pavilion *free*. The Sperry company had also a fine display of incandescent and other lights, for which it received the silver medal, and the other companies gold medals—not on account of superior lights, but because of their liberality. The Thomson-Houston company lights the cities of Oakland, San Jose and Sacramento, and is negotiating for Portland, Oregon, and Los Angeles, while the Brush system seems to have a monopoly of San Francisco, and with a shrewd business man and influential politician like P. B. Cornwall as its president, it would not surprise me to see this city lighted exclusively by that company, and gas superseded; but ere that occurs some of the city fathers will leave office wiser and richer men.

George S. Ladd, the President of the Telephone company, is also President of the Edison Incandescent Light Co., and he is waiting for a favorable moment to demonstrate to our people that his light is much superior to gas. He is at the present moment in excellent humor over the decision in the Bell-Drawbaugh suit, and even Mr. Sabin does not begrudge the various suits of clothes he lost on Blaine.

The Gold and Stock and American District companies, under one management, are almost exclusively owned by the Western Union Telegraph Co. Although the mining stocks do not create as much excitement as they used to do in years gone by, the united companies seem to be doing a good business. As the District company does most of the Western Union city delivery, it is thus enabled to make a better showing than would otherwise be the case, as the San Francisco District Co. is taking a great deal of its business away.

The Telephone company, under the management of Messrs. Ladd and Sabin, has in a measure reduced Western Union local receipts, they having exchanges in every town on the coast, and some of the most prominent are connected direct with San Francisco, where their wires are a net-work. Certain it is that business was never so dull in the San Francisco office as at present, and Mr. Rankin's eye moistens when he is ordered to dispense with four of his best men from the 1st of December. He regrets the necessity, but such events must occur if the telegraph is not properly patronized.

L. N. Jacobs is expected to succeed E. C. Fleming as night chief at the Western Union office, the latter gentleman being seriously ill. Mr. Jacobs received the Republican nomination for County Clerk, but failed to poll the necessary number of votes for election, partially because a third candidate was in the field, and partially because he stood by the Western Union during the strike. For this reason, the labor organizations went against him, and none so bitterly as the operators, who clearly demonstrated that they were more thoroughly organized than in July, 1883.

SAN FRANCISCO, CAL., Dec. 8, 1884.

BOSTON.

The Western Union Subterranean Line.—The American Electrical Exhibition.—Rumored Amalgamation of Electric Light Interests.—Gossip About the Telephone Patent Suits.—New Electric Light Plant.—Proposed Development of Long-distance Telephoning.—Harvard Students on Government Telegraphy.—Introduction of the Weston Incandescent Lamps.—The Western Union Abolition of Over-time.

THE result of the controversy between the city authorities and the Western Union Telegraph Co. relative to poles on Friend street, referred to in my last, resulted in the latter putting down an underground system, extending from the Eastern railroad station through Friend, New Washington, Devonshire and State streets to the Western Union offices. The system is simply iron pipes laid in a trench 2 feet deep with manholes every 450 feet. The cables will be drawn in. The newspaper electricians think that this settles the matter for all electric wires, and hug themselves to think how much they know about such plain and simple matters.

The electrical exhibition, after as many false starts as an agricultural horse trot, has finally opened the ticket office. The first opening was to be Nov. 24—then Dec. 1, afterwards Dec. 3—and it finally opened Dec. 8. The hesitation was owing to the fact that the principal exhibitors had not made up their minds to exhibit when the first opening date was announced. It would have been more attractive if some of the local characters known in the electrical line had been connected with the enterprise. Although the exhibition has been opened ten days the display is not large as yet. The principal exhibits are those of Edison, composed of lamps and his private exhibit; and that of the American Bell Telephone Co. The Arago electric light shows up well, on the outside and inside of the building. The historical collection is small, comprising Western Union and fire alarm models. The Dudley Electric Manufacturing Co. show a system of individual calls for telephone lines, and show it well. Seth W. Fuller exhibits a variety of electrical apparatus, etc. Blodgett Bros. exhibit their railroad time apparatus, etc. The New York Insulated Wire Co. is on hand. The New York Consolidated Electric Light Co. has its dynamo in position and its exhibit is progressing. Ocean telegraphy is graphically illustrated. The Rhode Island Telephone and Electric Co. has its clock system working—as have also the American Watchman's Time Detector Co., the Martin Automatic Fire Alarm Co., the Municipal Signal Co. and Orcutt's Electric Railroad Signal. The Bidwell railway looks well, composed of tracks and cars—the former encircling the gallery. The cars, two in number, are built with open sides; the first car carries the driver in front where the apparatus is located. The power is obtained from a Weston dynamo on Stanhope street, some distance from the building. The cars are lighted by electricity from the rails. The incubator man is here with his "electrical" exhibit. The "Orne" battery has a show case. Prof. Dolbear has his box on the main floor and illustrates his telephonic system; he has a Reis transmitter connected with it, to show that the Reis instrument *can* be made to talk, notwithstanding the sneers of an unbelieving world.

There are rumors of consolidation in electric light circles, in this city. The three companies—American, New England Weston and Brush have been engaged in a ruinous competition, and while not exactly losing money are not paying dividends. The consolidated stock appears to be an obstacle; as each company has a reasonable capital now; to consolidate to make money, means to squeeze somebody.

It is the world's news now, that the Drawbaugh claimant has gone to join the long line of which the Tichborne claimant is a shining example. The news of Judge Wallace's decision was first received at the American Bell Telephone office, in this city, and over their telephone line from New York—the brokers getting their information later by private wires. The stock of the company sold in the morning stock board at 220 and 215—but, after the brokers had picked the lambs clean, the stock shot up to 275—and holders expected to realize at 300, but the public did not come in with that tumultuous rush of former years, so there was a sag. The announcement by the company of a special dividend of 3 per cent. for holders to put in their Christmas stocking, sent it up again, but the first wave was the highest. The result was of course very gratifying to those who were fortunate holders of the stock; there were many, however, who *intended* to participate, but had not nerve enough to jump in. The Overland Telephone case, suspended last January in Philadelphia, will now be the next thing to settle; the judges in that case holding off, it will be remembered, to hear the decision in the case now decided, as the Drawbaugh evidence was introduced by the Overland people. Of course the Overland case was practically decided when Judge Wallace sat down so hard on Dan. With the Drawbaugh and Overland companies enjoined, the telephone field will be comparatively clear; whether the Baltimore and Ohio telegraph people, who are sponsors for the Meucci first-inventor-claimant will make a stand remains to be seen. The recent decision would seem to be a wet blanket to claimants whatever their pretensions; and the Meucci-man who evidently thought he could speak numberless miles through a hollow tube, using a battery and key for signaling, will not use up the "monopoly" very thoroughly.

A company has closed a contract with the American Electric and Illuminating Co. of this city, for the immediate installation of a complete 100 arc light plant, with accompanying machinery for incandescent lights and motors. Real estate is to be purchased and construction commenced immediately.

The statement comes from a director of the Bell company that among the enterprises to be pushed by the company is the long-distance talking business, and that soon New York and Philadelphia, and eventually New York and Chicago, will be connected, using the hard-drawn copper wire, such as now connects New York and Boston. Connections are to be made with subscribers by means of private switch-boards without the intervention of the central office.

The telegraphs of the country will surely not pass under the control of the U. S. government now, as the Harvard College students in the debate in the Harvard Union the other evening, settled that point and clinched it down hard by a vote of the members.

The New England Weston Electric Light Co. is now putting in the new large incandescent lamps of 125 candle power, along the line of available circuits. The light is very steady, pleasant to the eye, and is free from the disadvantages of the arc system, especially for interior illumination. Small lights of 16 candle power can be run from the same circuit.

The Western Union telegraph operators have been notified that hereafter they will be deprived of their "extra." This order reduces salaries in some cases $30 and $50 per month.

BOSTON, Dec. 18, 1884.

PHILADELPHIA.

Too Many Subterranean Enterprises.—Financial Embarrassment of the Sectional Conduit Co.—Referee's Decision on the Question of the Telegraph-Pole Tax.—Underground Privileges Granted.—

THE chief topic among electricians in this city is the "underground" problem. As there are some half-dozen different systems here—all claiming to be the best—it is a difficult matter to see where they all propose to make money out of their enterprises. To be a little more forcible than elegant, "somebody is going to get left." The embarrassments of the Philadelphia Sectional Electric Underground Co. seem to be on the increase. In my last letter to THE ELECTRICIAN AND ELECTRICAL ENGINEER I spoke of the trouble this company has been having in the shape of explosions that have occurred in their trenches, caused by the accumulation of foul air and gas. *Now* a new difficulty has been sprung on them, inasmuch as a judgment has been taken out against the concern for non-payment of a promissory note, amounting to $5,669.12, with interest. The most important piece of property belonging to the concern is said to be the conduit which extends from Third to Broad streets on Chestnut, with a branch to the Public Buildings, and another down Eleventh street a short distance. This conduit has been leased to and is now operated by the Electric Light and Power Co., which corporation is said to be controlled by men largely interested in the Underground company. The Councils have granted to the Underground company the right to lay conduits on Chestnut street, and this franchise is regarded as one of the most valuable assets of the company. The conduit and city franchise are estimated to be worth much more than the amount of the iron firm's claim, and it is intimated that the matter will be arranged before it comes to a sale.

The decision of the referee in the suits brought by the city against the Mutual Union, the Western Union and the Bell Telephone companies, who yesterday filed his report in the Court of Common Pleas, is of considerable importance. The claim was contested by the companies on the ground that it was exorbitant, and the referee, in his opinion, sustains this view of the matter strongly.

The city sued to recover an aggregate of $6,885, which, it was claimed, was due and owing by these companies for licenses for the year 1883 upon poles and wires, as provided in ordinances of January 6, 1881, and March 30, 1883. The entire amount claimed from all the companies for tax on poles and wires was $14,208, of which $9,500 was for the former and $4,658 for the latter uses If the referee's judgment is approved by the court, and the case is allowed to rest, a loss of $11,708 annually would result to the city from this source. The referee thinks $3,500 a reasonable charge. Superintendent Walker, of the electrical department, said this afternoon that the subject was purely a legal one now, and that if the tax is not proper Councils will be compelled to frame a new ordinance. "It is immaterial to me," the superintendent said, "what shall be charged, as I am required only to enforce the ordinances referring to my department. I can tell you, though, that the pole tax here is a dollar, while in other cities it is higher, being in Baltimore $2 per pole."

Superintendent Walker yesterday told the chairman of Councils Electrical Committee that the various companies owning overhead wires, who had been notified as to the penalty of a non-compliance of the ordinance requiring them to be placed underground, had informed him that the penalty would be paid under protest. The referee to whom the question of the legality of the ordinance was referred decided that as the penalty was in the nature of a tax upon the companies, Councils had no authority to levy it.

The committee considered favorably the ordinance granting the Baxter Overland Telegraph and Telephone Co. permission to lay a cable in certain streets from Point Breeze to Germantown. An amendment to the ordinance provides that the entire circuit of the cable be completed within one year from the date of the granting of the privilege. The ordinance granting permission to the Morse Underground Co. to lay its conduits in the streets was reported negatively, the representatives of the company having failed to appear before the committee.

PHILADELPHIA, Dec. 19, 1884.

WASHINGTON.

No Government Telegraph Legislation this Winter.—Underground Electric Light System.—Telephone Affairs.—Prospective Reopening of the Postal Office. —The New Baltimore and Ohio Building.—The War on Overhead Lines.

ALTHOUGH Congress has not formally taken a recess, it is as certain there will be no legislation before the 5th of January as if the usual adjournment over the holidays had taken place. Thus two-fifths of the session has gone and nothing has been done regarding the control of the telegraph by the government, unless it be in the nature of taking nought from nothing, for by the action of the Senate caucus on the order of business, so many other matters were put to the front that the bill of Senator Hill was left so far in the rear that it cannot hope to see daylight in the eight remaining weeks of the session. Senator Hill has consequently given up the effort, and has been looking to the House for something on which an effort for action in the Senate could be based. This being the situation of affairs, Mr. Money, chairman of the Committee on Post-offices and Post-roads of the House, has diligently sought to get a day assigned for the consideration of his bill, which proposes contracts by the government for a term of years for telegraphic service; but the obstacles have thus far been insurmountable, and as the time for final adjournment draws nearer the difficulties will increase. As I understand the case, the advocates of a *bona fide* government control of the telegraph are not satisfied with the bill of Mr. Money, and charge that it is inspired by the companies, while the companies do not desire it, but would prefer it to the threatened more radical legislation. They would prefer to be "let alone," and as there is therefore no powerful influence behind this measure it is not likely to make headway. Mr. Anderson, the author of one of the bills for a government telegraph, says the old companies would sooner have the Money bill for ten years than risk the future in Congress. There will be some speeches on the subject even if the bill does not come up. These will probably be made on the post-office appropriation bill when it comes up, or they may go into the *Record* on "leave to print," but there will be no legislation on the telegraph by this Congress.

The United States Electric Light Co. has completed its underground wires for lighting F street from 9th to 14th street, and has supplied the light for the past two or three weeks. The laying of the wires was quite expensive, as the concrete pavement had to be cut up, but the business men on the street generously contributed a sufficient sum to make up the difference, and the street is now beautifully illuminated. The lamps are placed on posts about 10 feet high at short intervals along the curb, the wires running up inside from beneath the ground, and are not visible. A further extension of this mode of street lighting is contemplated by this company. They already have a number of subscription lamps in front of business places on Pennsylvania avenue, which in some localities make this broad avenue quite brilliant. This company has an energetic management, and seems to be doing a good business. A semi-annual dividend of 4 per cent. was made on the 1st of July, and a like dividend has been ordered, payable January 1st. I am assured these are made from the net earnings, and that a handsome surplus remains in the hands of the treasurer. The company is now engaged in putting in 160 incandescent lamps in the printing office attached to the Treasury department and located in the Treasury building. This work is being done under the superintendence of Mr. Charles F. Burns, of the New York office. It will be completed soon after the holidays.

The Chesapeake and Potomac Telephone Co., a consolidation of the Washington, Baltimore and Maryland systems, has declared its usual semi-annual dividend. Under General Manager S. M. Bryan the telephone is regaining the popularity which was so badly shattered under the former management, when a purely local enterprise

W. F. Allen, late local manager of the Postal company, is here to reopen an office, and is looking up the old employés of the office. It will require some time for the two smaller companies to regain the footing they had gained before the attempt at consolidation.

The new railroad and telegraph office of the Baltimore and Ohio company was rapidly run up to the third story, when the cold weather put a stop to the work. The structure when completed will be quite imposing, and have a strong tendency to preserve the popularity of the old telegraph corner, despite the gradual movement of the business centre westward. In this connection it may not be uninteresting to state that 30 years ago all the telegraph offices—Morse, House and Bain—were located (and centrally, too) east of 6th street, with a single branch office in Willard's Hotel.

The war on overhead wires continues. No efforts have been made to compel those up to come down beyond refusing to permit new poles where the old ones are rotting away; but no new lines are permitted. An effort is being made to get the question into the courts, in order that its legal status and the powers of the commissioners and the rights of the corporations under the law may be judicially determined. The last utterances by the authorities were made on Wednesday by Commissioner Edmonds, who said that if citizens would examine the matter they would not complain of poles erected in the alleys. "The commissioners," he said, "have forced the telephone and telegraph companies to begin placing their wire underground in the streets. They leave the streets free, and we let them erect a distributing pole in the alleys. It would be impossible for them to go underground in the alleys, as they would have to dig up the citizens' property in order to furnish each patron in the square. As it is now, they run a distributing wire in the alley, and connect all the patrons, and that is a great deal better than having the streets burdened by the wires.

WASHINGTON, D. C., Dec. 20, 1884.

ELECTRICAL NEWS AND NOTES.

OPINION OF JUDGE WALLACE IN THE TELEPHONE CASE.

DECEMBER 1, 1884.

STATEMENT OF THE CASE.

This suit is brought to enjoin the defendants from using and furnishing to others for use the several inventions described in two patents granted to Alexander Graham Bell, of Salem, Massachusetts, being No. 174,465, bearing date March 7, 1876, for "Improvements in Telegraphy," and No. 186,787, bearing date Jan. 30, 1877, for "Improvements in Electric Telephony." The issues made by the pleadings are practically resolved into the single question, to which the proofs and arguments of counsel are mainly addressed, whether the patentee Bell, or Daniel Drawbaugh, of Milltown, in Cumberland County, Pennsylvania, was the first inventor of the electric speaking telephone.

Concededly Bell was an original inventor of the telephone, the principle of which with the essential means for its application, are described in his first patent, and of the improved apparatus described in his second patent. The fifth claim of the first patent is for "the method of and apparatus for transmitting vocal or other sounds telegraphically, as herein described, by causing electrical undulations, similar in form to the vibrations of the air accompanying the said vocal or other sounds substantially as set forth." This patent has been judicially construed in two cases in the Massachusetts Circuit; and in both cases it was substantially held that Bell was the discoverer of the new art of transmitting speech by electricity, and that the claim should receive the broadest interpretation to secure to the inventor not the abstract right of sending sounds by telegraph without regard to means, but all means and processes described which are essential to the application of the principle. American Bell Telephone Co. *vs.* Spencer, 8 Fed. Rep., 509. Same *v.* Dolbear, 5 Fed. Rep., 448.

In view of the conclusion reached upon the merits of the issue, it is not material whether Bell's inceptive invention did or did not antedate the time of filing his application for the first patent. That application was filed Feb. 14, 1876 It describes apparatus which was an articulating telephone, whether Bell knew it or not. Mr. Cross, an expert, caused apparatus to be made in conformity to the description and to drawings as shown in figure 7 of the patent, which proved itself to be an operative, practical telephone. Probably the date of his inceptive invention might be carried back to July, 1875, but, irrespective of the time of the invention, the justice of his claim to be an original inventor of the telephone must remain unchallenged. It was through him also that the telephone was made known to the scientific public, and thence introduced into commercial use.

THE DEFENDANTS' ANSWER.

The defendants contend that, long before Bell had perfected his invention, and long before its mental conception by him, Drawbaugh had not only made the same invention, but had perfected improvements in organization and detail which Bell never reached, and which were only reached years afterwards by the work of many other inventors in the same field of improvement. Their theory of the facts is stated with substantial accuracy in the answer to the bill of complaint. The answer, among other things, avers that Drawbaugh "was and is the original and first "inventor and discoverer of the art of communicating articulate "speech between distant places by voltaic and magneto electric-"ity, and of the construction and operation of machines and in-"struments for carrying such art into practice; . . that the "said electric speaking telephones so constructed and success-"fully and practically used by him contained all the material "and substantial parts and inventions patented" in the two patents granted to Bell; and also contained other important and valuable inventions in electric and magneto telegraphy; . . "that some of the original machines and instruments invented, "made, used and exhibited to many others long prior to the "alleged inventions of Bell are still in existence, and capable of "successful practical operation and use, and are identified by a "large number of persons who personally tested and used and "know of their practical operation and use in the years 1870, "1871, 1872, 1873, 1874, and both subsequently and prior there-"to; . . that said Drawbaugh for more than ten years prior "to 1880 was miserably poor, in debt, with a large and helpless "family dependent upon his daily labor for support, and was "from such cause alone utterly unable to patent his said inven-"tion or caveat it, or manufacture and introduce it upon the "market; and that said Drawbaugh never abandoned nor "acknowledged the claims of any other person thereto, but al-"ways persisted in his claim to it, and intended to patent it as "soon as he could obtain the necessary pecuniary means there-"for."

DRAWBAUGH'S STORY OF HIS INVENTION.

Drawbaugh, in his testimony, adopts the statements of the answer as true. He also testifies that he commenced his experiments with the electric telephone as early as 1866; that prior to or as early as in 1867 he had made apparatus (in which he employed a teacup as the transmitter) through which speech could be transmitted feebly and incoherently; and that as early as the time of the birth of his son Charles he had so progressed that his wife, who was then confined to her bed, could, by listening with one of his instruments, hear the words spoken by him in the other instrument in a distant part of the house. His son Charles was born in 1870, and, if Drawbaugh's narrative is true, he had succeeded at that time in transmitting speech distinctly through the instruments, although whispered words would not be accurately heard. He describes instruments which, he says, were made by him from time to time, as experiments which led him from one movement to another. He testifies that he thinks he made his first telephone apparatus prior to November, 1866, and is positive he had it before he moved his shop to the "Clover-Mill," in 1867.

As he describes it, the body of the transmitter was a porcelain teacup, the diaphragm was of membrane, the electrodes interposed in the circuit were two copper discs, the upper one of which was connected to the diaphragm by a wire, so as to vary its pressure upon a low conductor of fine earth or pulverized charcoal interposed between the discs through the action of the sound waves upon the diaphragm; and the receiver was a tin can without a top or bottom, having a membrane diaphragm stretched over one end, connected by a tense cord to an armature supported on a spring, and arranged close to the poles of an electro magnet in the electric circuit. He testifies that subsequently he constructed apparatus upon the same general principle, with some change of detail; and he produces Exhibits "F" and "B," —the former a transmitter and the latter a receiver—as the remnants of the original instruments. Exhibit "F" is a glass tumbler; and he states that at first he used a membrane diaphragm over it, and then one of thin metal; and that for the conductor he used pulverized carbon or carbon mixed with bronze powder, and used various tops or mouthpieces to speak into it. The Exhibit "B," he says, was the receiver; and in this he had discarded the string and the spring of his earlier receiver. He says that experiment led him to improve the transmitter "F" by substituting a metal diaphragm in place of membrane, and he produces a sketch. A reproduction of this instrument has been made by him for use in the proofs, which is designated as "Exhibit F reproduced." In this the mouthpiece is modified in size and in distance from the diaphragm.

He made, according to his testimony, a new receiver of more perfect construction, and produces the remnant of the original, which is designated as "Exhibit C." As he describes the instrument, it was a decided advance upon the former receiver. In using this, he says he tested it also as a transmitter with some success, and then improved it by placing a permanent magnet against the heel of the electro magnet, and thus made a magneto telephone. A reproduction of such an instrument as he describes is made and referred to in the proofs as "Exhibit Reproduced C." After Exhibit "C," he produces Exhibits "I," "A," "E" and "D," as likewise original instruments, made respectively in the chronological order of their production as exhibits. He states that "I" was used by him as a companion instrument to "C." Exhibit "A" discloses a modification of form and a higher degree of mechanical adaptation.

The last two, "D" and E," are concededly perfect, practical instruments; and, according to the testimony of Mr. Benjamin, an expert witness for the defendants, would compete successfully for public patronage with any magneto telephone which had been introduced into use in 1882. It is asserted of these instruments by counsel that no higher development of the magneto telephone has been reached at the present time than is indicated by Exhibits "E" and "D." Drawbaugh does not attempt to fix the time at which he made any of these instruments, or even the year. He testifies, however, that he made all of them prior to the time the "Axle Company" commenced business, which was in December, 1874, except "E" and "D," which were made about that time.

THEORY OF THE DEFENCE.

The theory of the defendants is, that Exhibits "F" and "B" were used by Drawbaugh in 1867, 1868 and 1869, Exhibit "C" in 1869 and 1870, Exhibit "I" in 1870 and 1871, Exhibit "A" in 1873 and 1874; and that Exhibits "E" and "D" were made in January or February, 1875, although cruder instruments essentially similar were made somewhat earlier. It is in proof that 33 patents were granted for improvements in telephones in 1878, 64 in 1879, more than 100 in 1880, and 94 in the first 6 months of 1881. According to the theory of the defendants, therefore, as early as February, 1875, Drawbaugh had not only distanced Bell in the race of invention, but also Gray and Edison, and had accomplished practically all that has since been done by a host of other inventors.

Digitized by Google

The case for the defendants must stand or fall by this theory. The proofs leave no room for fair doubt that defendants contention is substantially true, or that the defence has no foundation in fact. It is either true that Drawbaugh had long been treading his solitary path of investigation and experiment in poverty and obscurity, but had perfected his work when the inventions of other explorers were in embryo, or his story is an ingenious fabrication. And, as will hereafter appear, if the defence is a fabrication, many disinterested witnesses have contributed innocently to give it color and strength; but Drawbaugh has deliberately falsified the facts.

POSITION OF THE COMPLAINANT.

The complainant starts with the benefit of the presumption of law that Bell, the patentee, was the inventor of that for which the Letters Patent were granted him. Whoever alleges the contrary must assume the burden of proof. Evidence of doubtful probative force will not overthrow the presumption of novelty and originality arising from the grant of Letters Patent for an invention.

It has been frequently held that the defence of want of novelty or originality must be made out by proof so clear and satisfactory as to remove all reasonable doubt. Washburn *v.* Gould, 3 Story, 227; Smith *v.* Fay, 6 Fish, 446; Hawes *v.* Antisel, 2 B. & A., 10; Patterson *v.* Duffy, 20 Fed. Rep , 641; Wood *v.* Cleveland Rolling Mill Co., 4 Fish, 560; Parham *v.* American Button Hole Co., do., 482. In U. S. Stamping Co. *v.* Jarrett, 18 Blatch., 469; Blatchford, J., said the defendant had not fulfilled "the necessary obligation of showing beyond any reasonable doubt" that Weber (the alleged prior inventor) was prior to Heath (the patentee). In Coffin *v.* Ogden, 18 Wall., 129, Mr. Justice Swayne delivering the opinion of the Court, stated the rule applicable to the defendant as follows: "The burden of proof rests upon him, and every reasonable doubt should be resolved against him."

To overthrow this presumption and disprove that Bell was the first inventor, the defendants introduce the testimony of nearly 200 witnesses tending to prove the priority of invention by Drawbaugh. As the complainant concedes that Exhibits "E" and "D" are highly organized, practical telephone instruments, and fully capable of perfect articulation, the patents are invalidated if these instruments were in existence at the date of Bell's invention; and, as will hereafter appear, either they were in existence as early as in 1875, or it is incredible that they existed at all until long after Bell's first patent had been granted, and his invention had attracted general public attention at the Centennial Exposition and elsewhere.

In the argument for the defendants, great stress is placed upon the evidence of a gradual and natural development of Drawbaugh's invention shown by the original instruments produced, beginning with Exhibit "B," and ending with the perfect magnetos "E" and "D"

It is strenuously urged that these exhibits fortify his testimony describing the instruments no longer extant, and mark the origin and culmination, beginning with the cup machine and Exhibit "F" of two separate lines of invention; one leading to the battery telephone, in which the undulatory vibrations are controlled by variations in the resistance of the circuit; and the other to the magneto telephone, in which the vibrations are created in the act of producing the current itself.

SUMMARY OF DEFENDANTS' TESTIMONY.

The general theory of the defence is substantiated by three classes of witnesses: those who heard of the existence of Drawbaugh's "talking machines" at various times; those who talked through the machines on various occasions, or heard others talk through them; and those who attempt to identify one or more of the exhibits as the instruments they saw used. Only an outline of their testimony will be given.

More than fifty witnesses testify to having heard of the talking machines prior to Feb. 14, 1879.

Of these witnesses, 3 think they heard of them in 1869; 3 in 1870; 2 in 1871; 5 in 1872; 3 in 1873; 3 prior to 1873; 8 in 1874; 2 in 1875; from 1866 to 1876, 1; from 1868 to 1871, 1; from 1868 to 1873, 1; from 1869 to 1870, 1; from 1869 to 1876, 1; from 1871 to 1872, 2; from 1872 to 1873, 1; from 1873 to 1874, 1; from 1873 to 1875, 3; from 1874 to 1875, 1; from 1874 to 1876, 1; from 1872 to 1876, 1; prior to 1869, 1; prior to 1872, 2; prior to 1875, 1.

Sixty witnesses do not attempt to identify any particular instrument, but testify that they saw a talking machine or talked through it, or heard it talked through at Drawbaugh's shop on occasions subsequent to 1867, and most of them fix the occasion as prior to 1876. The substance of the testimony of some of them will be given.

Wilson G. Fox testified that he saw the talking machine at Mr. Drawbaugh's shop about the year 1867 or 1868, when the old Faucet company was in operation there. Prior to March, 1871, the witness was employed in the carding room of the Harrisburg Cotton Mill, and Drawbaugh came there to get material to wrap his wire to use for the talking machine. Henry Bonholtzer testified that he was at Drawbaugh's shop in 1869, and saw talking machines there. Margaret Brenneman testified that she saw the talking machines at Drawbaugh's shop in 1869. Abraham May testified that he did work on Daniel Hart's house at Milltown in August and September, 1870, of which he produces his account books; that he never did any work for Daniel Hart after that; that while doing that work he was at Drawbaugh's shop to get a boring machine mended, which he was using in the work, and Drawbaugh showed him his talking machines, and talked through them from one floor of the shop to another. The witness understood and heard through the machine the words that Mr. Drawbaugh spoke into it. His testimony is corroborated by Jacob H. Kilmore, William H. Martin, and John A. Smith.

Cyrus Orris testified that he saw Drawbaugh's talking machines at different times, from about the 1st of April, 1871, down to 1880, and took his son-in-law, Jacob E. Smith, to Drawbaugh's shop to see the machines about April 1, 1871. Benjamin K. Goodyear testified that in 1871 he seized the personal property of George W. Kissinger, of Milltown, upon an execution issued Nov. 13, 1871; that on Dec. 4, 1871, the attached property was appraised, and on that day witness went to the workshop of Daniel Drawbaugh to find J. B. Drawbaugh, to summon him as an appraiser, and had to wait for him there a short time; that while waiting there Daniel Drawbaugh showed him his talking machines, and talked through them to him, and witness heard him speak, and understood distinctly the words that he spoke through the instrument; and that he was never in Drawbaugh's shop afterwards, so far as he can recollect.

George Natcher testifies that he lived at Milltown in 1871-1872, and never has been in the town since Aug. 9, 1872; that while living there he was at Drawbaugh's shop, and saw and talked through the talking machines on different floors, and listened at the same machine and understood what was said through it. Mrs. B. B. Spangler, a sister of George Natcher, testifies that she moved away from Milltown in 1872, and never has been there since; that she talked into Drawbaugh's talking machines while she lived there; and that she was so small that Harman Drawbaugh had to lift her up to enable her to talk into the machine. Mrs. Mary Free testifies that she was with her sister, Mrs. Lydia Drawbaugh, at Drawbaugh's shop, in September, 1872, when he talked through the machines to them, and she remembers hearing through the machines, "Good afternoon, ladies!" Drawbaugh told them that the machines operated by electricity.

Mrs. Lydia Drawbaugh testifies that she saw the talking machines in September, 1872, her sister, Mrs. George Free, being present. David M. Ditlow testifies that he saw Drawbaugh's talking machines about 1872, when Drawbaugh talked through it, and witness heard and understood through the machine what he said. David K. Ernest testifies that he was at Drawbaugh's shop with John B. Bloser about the middle of June, 1872, and talked with Drawbaugh about the talking machines, and thinks he saw them at that time. This testimony is corroborated by John Bloser. N. W. Kahney testifies that he saw the talking machines about 1872. William H. Martin testified that he was at Milltown with John Keefauver, to get George Hosler to make him a pair of boots. Hosler lived at Milltown only from March, 1872, to March, 1873. At that time witness and Mr. Keefauver went down to Drawbaugh's shop, and talked through the talking machine, from the basement to the attic, and heard and understood what was said through the machines. They talked and listened at the same instrument.

John F Keefauver corroborates Mr. Martin, and also states that he talked through Drawbaugh's talking machine with Jacob M. Sadler, in April, 1873, prior to the death of George B. Hick, and that about two or three years before he saw the talking machines he had heard a good deal about them, and first heard of them at a place seven miles west of Carlisle. Wm. W. Snyder testifies that he was at Drawbaugh's shop on Wednesday, Feb. 5, 1873, and saw the talking machines. He verifies the date by an entry in his diary. Jacob Barber testifies that he was a candidate for the office of County Commissioner of Cumberland County in the summer of 1873, and, in connection with his canvass, went to Drawbaugh's shortly after the death of George B. Hick. While at Drawbaugh's shop he saw the talking machine, and was never in the shop after July or August, 1873.

Ezekiel Worley testifies that about the year 1873 he saw the talking machine at Drawbaugh's shop. His statement is corroborated by John K. Taylor. Abraham Ditlow testifies that he knew of Drawbaugh's talking machine in 1874, and saw it and talked through it at that time. He had forgotten the fact, but was reminded of it by Mr. Alexander Milner, of Porter County, Ind., whom witness told about it in May or June, 1876, in Indiana. William Eppley testifies that he visited Drawbaugh's shop for the last time in May or June, 1875; that he was there several times during the two years preceding that period, and had seen talking machines. Jonathan Fry testifies that he was at Drawbaugh's shop with Mr. Hamme and Mr. Frederick in the winter of 1875-6, and saw the talking machines there. Jacob Evans testifies that he was at Drawbaugh's shop with his wife, his brother Andrew, and his sisters Margaret and Sarah, about Dec. 1, 1875, and saw and talked through the talking machines.

Digitized by Google

Henry L. Hamme testifies that he was at Drawbaugh's shop either in the last of January or the beginning of February, 1876, in company with George Frederick and Jonathan Fry, and saw and talked through the talking machine at the time; that he heard and understood very plainly what was said through the machines, even when Mr. Drawbaugh talked in a whisper. George Frederick testifies that he was at Drawbaugh's shop with Mr. Hamme and Mr. Fry in January or February, 1876, and saw the talking machine. S. S. Rupp testifies that he was at Drawbaugh's shop with Mr. Hammacher and his scholars on Feb. 1,1876, and recollects that Mr. Drawbaugh at that time spoke about a machine that he had which he called a talking machine, but the witness was interested in other things and did not pay much attention to it. George H. Bowman testifies that he saw talking machines in Drawbaugh's shop in February, 1876, at which time somebody was talking to Mr. Drawbaugh through them. Charles L. Drawbaugh testifies that he saw and talked through the talking machines at Drawbaugh's shop a year or more prior to May 1, 1876, and heard and understood what was said.

The third class of witnesses are those who identify more or less positively one or more of the several exhibits as the instruments used by them, or which they saw used by others prior to March 7, 1876. Exhibits "F" and "B" are identified by the following witnesses: Brooks saw them in 1874; Smyser, in 1872; Eberly, before December, 1870; Wagner, in the fall of 1874; Freese, in 1869 or 1870; Yetter, about Christmas, 1875; Fry, spring of 1875; Carl, in 1870; Scherick, in 1869; Balsley, between 1870 and 1874; Good, before 1872; Kahney, in 1871 or 1872; Schettel, about 1872; Nichols, in 1875; Renneher, in May, 1875; Weber, late in 1874; Stephen, before 1875; Shireman, about 1872; Hawn, about 1872; H. B. Eberly, in May, 1873; J. C. Smith, between April, 1872, and April, 1873; Sternberger, in October, 1871; Fettrow, in April, 1876; Halsinger, prior to 1876; Shoop, in 1869; H. F. Drawbaugh, in 1872; Zimmerman, in 1871; Bates, in 1874; Guistweit, in July, 1870; Hale, in fall of 1873; Stone, in June, 1871; Free, in June, 1872; J. A. Oyster, in June, 1875; Harmon K. Drawbaugh, in January, 1871; J. B. Drawbaugh, in 1869; G. W. Drawbaugh, in 1870; Lenseman, in July, 1871; Fisher, in 1868 or 1869; Hubler, in fall of 1873; Updegraff, in 1874; W. H. Decker, in 1873; and a number of other witnesses saw one of these two exhibits.

The identification of Exhibits "C," "I" and "A" is made by a smaller number of witnesses. Some of them think they saw "C" in 1870, and others at various dates after that and as late as March, 1876.

One of the witnesses thinks he saw "I" in 1871, the others locate the occasions in 1873, 1874 and 1875. Some of the witnesses think they saw "A" as early as 1872, one of them in 1870; but most of them saw it, they think, in 1875.

Exhibits "E" and "D" resemble each other very closely in appearance, and most of the witnesses produced to identify them saw both at the same time. They locate the time as follows: Fry, laborer, in May or June, 1875; Fry, farmer, in April, 1875; Bayler, in June, 1873 (Exhibit "D"); Springer, after April, 1876; Shettel, about 1875; Shoop, after February, 1877; Musser, in June, 1876 (Exhibit "D"); Millard, in 1875; Holsinger, in summer of 1875; Shoop, in 1874 or 1875; Bates, between 1874 and 1877; Dellinger, in March, 1876 (Exhibit "E"); Guistweit, between 1870 and 1876; Bowen, in September, 1878; Hale, in fall of 1875 (Exhibit "D"); Michael Dillinger, in November, 1877 (Exhibit D"); Harmon K. Drawbaugh, in January, 1875, and helped put up wire for them; J B. Drawbaugh, prior to Jan. 26, 1875; George W. Drawbaugh identifies all the exhibits as seen by him some time between 1871 and 1878; Updegraff & Musser, in 1876; Smith, in 1872 or 1876 (Exhibit "E"); May, in 1876 (Exhibit "D"); J. H. Smith, in May, 1876 (Exhibit "D"); Decker, in 1874 (Exhibit "D"); Vannasdale, in February, 1875; Evans, in fall of 1875; Mrs. Erb, in fall of 1875; S. E. Evans, in fall of 1875 (Exhibit "D"); M. E. Evans, in fall of 1875 (Exhibit "D").

Some of the witnesses who identify exhibits identify the whole series. Other witnesses besides those named identify one or more of the exhibits as seen by them at times subsequent to the date of Bell's application for his patent. Some of the witnesses who identify one or more of the instruments exhibited to them by Drawbaugh as the Exhibits "F," "B" or "C" saw or used them in 1875 or 1876. Among these are the following, to whose testimony a reference will be made:—

Mr. Springer testifies that he repeatedly talked and listened with Drawbaugh through the instruments after the 1st of April, 1876, using Exhibits "F" and "B" as the instruments. Mr. Musser testifies that he talked through "F" and "B" in June, 1874; but the proofs show that this occasion was as late as in the summer of 1876. Mr. Moore, who is produced to show that Drawbaugh applied to him to acquire an interest in the invention, testifies that the talking machine which Drawbaugh produced was Exhibit "B." This was in May, 1875. Mr. Bayler testifies that he talked through "F" and "B" in 1873; but the proofs show that the occasion was between 1875 and 1877. Mr. Nichols locates the middle of January, 1875, as the time when he saw Exhibit "B" in use.

DRAWBAUGH'S TALKING MACHINES WERE ELECTRIC.

That the talking machines referred to by the witnesses were electric instruments is clearly established. Drawbaugh testifies explicitly that they were always used with a closed circuit, and without breaking the current, some of them being battery telephones and some magneto telephones. He always represented them as actuated by electricity to those to whom he explained or described them, and claimed his invention would supersede the telegraph. His assertions show them to have been electrical instruments.

He stated to the witness Shank "it was the greatest invention ever known. If he had the means to go on with it, they could talk, or rather be a time to come as to talk, to the old country, same as we can talk here." To Zacharias, that "he could run it out for miles, and parties could talk in at one end and be heard at the other end, the same as persons in a room together." To Smith, that "parties between Harrisburg and Philadelphia could communicate as if they were speaking together; there would hardly be any limits;" it was an "instrument to convey the voice, to supply the place of the telegraph;" to Smyser, that it would work "from here to California;" to Fry, that one "can talk as far as the wire goes;" to Carl, that "he could hear a man talk from that place to New Cumberland or Harrisburg, and understand distinctly what he said;" to Sherwick, that it was "better and handier than the telegraph; that you could just talk through it in place of writing;" to Balsley, that "by attaching two wires you can hear it away off; the telegraph is nowhere with it;" to Kahney, that "he could talk the same for miles as he could for a short distance;" to Shettel, that, "if he had a wire from the shop in connection wlth the telegraph wires at White Hill, he could talk to Mechanicsburg by having a machine there or an instrument in the office; that it would be better than telegraphing, and that it would be worth a great deal of money;" to Reneker, that "he thought he could make it that he could talk through to Harrisburg; he thought they would take the place of telegraphing;" to Weber, that "it beats all the others of my inventions; he could carry sound, or rather talk, as far as Shiremanstown;" to Hawn, that "he would be able to operate that a man preaching in New York, that a congregation in Philadelphia would hear the same sermon;" to Kahney, that "he could just as easy speak ten miles as one, or any distance he would choose to;" to Rupp, who was there with Hamacher, that "it was worked by electricity, would take the place of the telegraph, and that he could make it so that he could talk to San Francisco;" to Musser, that "he was going to make a machine to talk from Harrisburg to Philadelphia, and it would be cheaper and quicker way than telegraphing;" to Smith, that "he believed they could talk for a hundred miles;" to Fettrow, that "I could speak ten, fifteen or twenty miles, or even to California, if there was a wire extended;" to Wisler, that "he could attach a wire to it and talk for ten miles, as far as he could have a circuit around;" to H. F. Drawbaugh, that "he could talk across the continent;" to Free, that "the talking machine could be used to talk at a long distance—from Philadelphia to California;" to Landis, "that it could be used a thousand miles; it would take the place of the telegraph;" to Lenig, that "he could talk hundreds of miles through that;" to Updegraff, that, "instead of using the old mode of telegraphing, he could talk directly through the wire; he thought he could talk as far as you could use the ordinary telegraph wire;" to Draper, that "he thought it was, or would be, one of the greatest inventions of the age, and would take the place of telegraphing;" to A. Evans, that "he could take this machine and talk clear out to Europe, cross the ocean;" to Eicholz, that "if he could only get some one to help him once, he would run it to Harrisburg, and convince them, and then he would run it from Harrisburg to Philadelphia."

He stated to the witness Shank that "it works by electricity;" to Smith, "it was by electricity;" to Nichols, that "the sound was conducted by electricity;" to C. Eberly, that the instruments were "to convey sound by electricity;" to Coudry, that "they were operated by electricity;" to Shoop, that "it operated by a battery;" to Shireman, that "they operated by magnetism:" to Hawn, that "they would be operated on by a battery;" to N. W. Kahney, that "the machine was operated by electricity, by a battery;" to Zimmerman, that "it was electricity that would pass it over the wires; that it would carry the sound right along;" to Hale, that "it was driven by a magnet;" to H. K. Drawbaugh, that "the sound could be carried to a distance on a wire by the use of electricity;" to Lenig, that "electricity was used in connection with it;" to Prof. Heiges, that "in connection with a talking machine both magnetism and electricity were applied;" to Goodyear, that "his talking machine was also done by electricity over wires;" to Woods, that "it was to be an electric machine used in place of telegraphing;" to Young, that "it was an electric talking machine, which he had invented."

IS DRAWBAUGH'S STORY CREDIBLE?

Thus Drawbaugh is corroborated by a cloud of witnesses whose testimony tends to substantiate his narrative. Without

Digitized by Google

stopping at this point to consider the credibility and probative force of their testimony, it suffices to state that, although some of the witnesses seem to have been reckless and unscrupulous in their statements, the great body of them are undoubtedly honest witnesses. It is impossible, however, to believe that Drawbaugh can be mistaken in the substance of his testimony, and the conclusion cannot be ignored that either his testimony is true in its essential parts, or his narrative has been manufactured to fit the exigencies of the case. In order to ascertain what effect is to be given to the corroborative proofs, it is important to determine whether Drawbaugh is an honest witness, or whether he has intentionally falsified collateral facts, and is therefore to be deemed discredited.

If the defence is to be believed, he had been experimenting with his talking machine from 1866, and had successfully transmitted speech as early as 1870, if not before that time. He testifies that he had used Exhibits "B" and "F" in transmitting speech for two or three years before he made Exhibit "C." According to the theory of the defendants' Exhibit "C" was made in 1869 or 1870. At that time he had reached a secondary stage in the development of his invention, and certainly as early as in 1872, when Exhibit "C" had received its latest modifications, the invention had passed out of the period of rudimental forms embodying principle merely, into a form embodying nice details of construction, and had reached a perfection not reached by Bell in his earlier patent. Drawbaugh was well aware of the merit and of the great pecuniary value of the invention; he had obtained patents for several inventions of minor value; yet from 1870 until July 1880, he did not apply for a patent for the telephone.

THE STORY OF DRAWBAUGH'S POVERTY DISPROVED.

It was of the first importance to explain the reason of his inaction, because it seems incredible that the inventor of the telephone should not only omit to patent it as soon as he could, but should also remain silent for years after others were winning the fame and profits of the invention. Only one explanation was possible, and that has been attempted. As stated in the answer, and in his testimony, it is that he was unable to do so by reason of his poverty. The answer alleges "that for more than ten years prior to 1880 he was miserably poor, and utterly unable to patent his invention or caveat it. He was asked the question: "Do you mean to have it understood from your last answer that there was any other reason for some period prior to 1870, except your poverty, whether greater or less, which prevented you from patenting your invention, or filing a caveat for it?" His answer was: "If I understood that right there was no other reason that I can think of now." He proceeds to state that Exhibits "F" and "B" exhibited the principle perfectly enough to patent.

In the elaborate efforts of the defendants to substantiate the theory of Drawbaugh's inability from poverty to patent his invention much testimony has been produced to show, and which does show, that he was always more or less in debt, often a borrower of small sums of money, was dilatory in paying his debts, and used to plead his inability when dunned, and was often sued and judgments and executions were obtained against him; but it is clear from a few plain facts that the theory of extreme poverty is unfounded, and that Drawbaugh is dishonest in putting it forward. In 1867 and 1869, besides what he received for his wages, he received $5,000 from the Pump Company for his faucet invention, besides $1,000 in the stock of the concern. On the first day of April, 1869, he received $1,000 from one Gardner, for the sale of a half interest in a faucet invention. He invested $2,000 of the $5,000 in real estate, lost $400 of it in an apple speculation, and used the $1,000 received from Gardner to buy a house and lot for his father Between 1867 and 1873 he paid $1,200 to the Drawbaugh Manufacturing Company for assessments on his stock, besides $870 in labor; and in July, 1873, received from that company $425 cash in settlement of its affairs.

From 1867 to April, 1872, he was the owner of real estate, for which he had paid $2,300 in the fall of 1867, and upon which he expended in improvements, in the spring of 1868, from $300 to $400, and which was encumbered only by a prior lien for $300. In the spring of 1872, he encumbered it for $1,000, not as a principal, but as a surety. He was in receipt of $110 annually, as rent, for a part of this property, occupying the rest himself, until he sold it in 1876, and bought another house in the town of Mechanicsville. He was always in receipt of fair wages for his labor.

From April 1, 1875, to April 1, 1876, he received nearly $450 for wages from the Axle Company, irrespective of his earnings from other sources, and declined steady work at times, because he could make more by job work. Thus it appears, that although at times it was not convenient for him to pay his debts, or he was careless or indifferent, he had not only the means of raising money during all this period, but that on many occasions he had means for investment and for speculation. The pretence that he could not raise the fees to caveat or patent his invention is transparently absurd.

He was accustomed to prepare specifications of patents, and was a maker of models, and advertised himself as an inventor, designer, and solicitor of patents. During the time he was experimenting on his talking machine, and before he applied for a patent, he found time and materials for experimenting with and making the Giffard injector for steam engines, the autograph telegraph, the magneto dial telegraph, the magneto key, the automatic fire alarm, and the electric clock. During this period he was a friend of Mr. Weaver, a patent solicitor, who frequently gave him advice and professional assistance, in return for mechanical services rendered by Drawbaugh, and who drew specifications for him for a measuring faucet and for the magnetic clock. If he was not competent himself to make an application for the patent, it cannot be doubted that, with the assistance of Weaver, he could have made a proper application at a trifling outlay, if any, beyond the fees of the office.

Drawbaugh devoted a good deal of time between 1867 and 1878 to the invention and construction of his electric clock; and the time and money expended by him in experimenting and constructing this clock in its various forms, especially those made in 1877-1878, was much more than would have enabled him to patent his talking machine. These clocks were built by him with his own tools and out of his own money, and to build them economically he made a gear-cutting machine, which must have cost him more than it would to patent his telephone. In April, 1878, he received $500 from the Electric Clock Company for the privilege of using his clock invention.

DEFENDANT'S TESTIMONY ON THIS POINT EXAMINED.

In order to fortify the theory of Drawbaugh's inability from poverty, to patent his invention, the defendants have attempted, by testimony from him and from others, to show that he was extremely solicitous to patent it, and tried to induce others to furnish the means. Mr. Springer testifies that "his (Drawbaugh's) whole mind appeared to be on his talking machine. He told me that many a night he didn't sleep, just studying how to improve it." After May, 1872, according to the testimony of Jacob Hawn, the talking machine superseded the clock in Drawbaugh's interest. According to Mr. Holsinger, from 1873 to 1876 "he appeared to be crazy on it. I often tried to get information from him on other subjects, and about half a minute's talk would turn him right on the talking machine."

Henry F. Drawbaugh, his brother, testifies: "Every time I was down there, from the summer of 1872 to 1879 or 1880, he was working at it, and talking, and wanted me to go in with him and furnish means." Mr. Bates says he "was in Drawbaugh's shop eight or ten times between the summer of 1874 and the fall of 1877, and "his general conversation was about the talking machine; said he would like to get it patented, but had not the means, and could make a fortune out of it." Drawbaugh testifies as follows: "Question. A good many witnesses have testified that you were at various times talking of patenting your electric-speaking telephone invention; what is your recollection about that? Did you intend to patent it or not? Answer. Yes, sir; I intended to patent it. I had spoken to a number of persons to assist me. I would state to them that I would give them an interest in the invention for them to furnish the money to have it patented. Question. Why did you not patent it with your own money? Answer. I didn't have any money. Question. At how early a time did you have the intention of patenting it? Answer. I could hardly say how early. I spoke to persons even at an early time. I spoke to Christian Eberly. It may have been prior to 1870, I spoke to Frank Lee. I spoke to them about taking an interest. They were among the earliest. I can't remember all the persons, as I had spoken to a great many. Lee is not a witness, having died in 1872."

Christian Eberly locates the time as between 1867 and 1870. He had been a partner with Drawbaugh in a number of inventions, and was a capitalist. He was asked, "When Mr. Drawbaugh showed you his talking machine, state whether he proposed to you to go into partnership with him, and furnish the money for that also, as you had before that time on the other inventions?" He answered: "Not altogether; he intimated that he would take me in. I don't recollect as I said anything, or what I said." The witness was often in Drawbaugh's shop subsequently, in 1871, 1872, and 1873, but mentions no other proposition."

The only other persons Drawbaugh specifies as having been applied to by him are Capt. Moore, Henry Bayler, and Simon Oyster. Oyster was not called as a witness. Capt. Moore was examined as a witness for the defendants, and his testimony is significant. He was the principal of the Soldier's Orphan School, an institution in the vicinity of Eberly's Mills, and was the secretary and treasurer of the Axle Company, a concern that in part occupied Drawbaugh's shop in 1875 and 1876. He testifies that about May, 1875, Drawbaugh showed him a talking machine; said he was unable to patent it himself, and desired witness to "go in with him and get a patent." He states that he told Drawbaugh he didn't want to go into any new inventions, but that it would be a fortune to any person bringing it out, if it could be put to practical use. He identifies "Exhibit B" as the only machine shown him at that time by Drawbaugh.

Digitized by Google

Although he and Drawbaugh maintained intimate business relations for a year after that time, the subject seems never to have been referred to again. Mr. Moore was an intelligent capitalist. It is strange that Drawbaugh should have shown him "Exhibit B," one-half of the crude instrument of 1867-1869, if the perfect instruments "E" and "D" were in existence; and more strange that the subject was never mentioned again between them, or that no attempt was made to speak through any machine, if they had any faith in the value of the invention.

Mr. Bayler, the other witness, carried on lumbering and a saw mill from 1873 to 1877, in the vicinity of Milltown, and employed Drawbaugh frequently to repair machinery. He testifies that in June, 1873, Drawbaugh showed him the talking machine, and he said to Drawbaugh, "Why, Dan, that is virtually a talking telegraph," and advised him to take out a patent for it; to which Drawbaugh replied, "If I had the means, I would. If you'll advance me the means to procure a patent, I'll give you a half interest." The witness continues: "Generally on him meeting me he would urge it, urge me to take an interest by furnishing him the means to take out a patent." He also identifies Exhibits "F" and "B" as the instruments shown him by Drawbaugh. But his books show that during all the time from April, 1873, to May, 1876, he owed Drawbaugh more than the fees necessary for procuring a patent.

The defendants produce other witnesses to prove that from 1870 to 1879 Drawbaugh was showing his telephone, adverting to his property, and trying to induce somebody to assist him. Mr. Herr may be cited as an illustration. He testified that in 1870 or 1871 Drawbaugh wanted money to get a caveat to secure his invention, and told the witness if he would help him, or procure any person to assist him, he would give him a half interest. Without adverting further to the testimony on this subject, it is sufficient to say, in view of the fact that there never was a time from 1867 to 1880 when Drawbaugh did not have the money to caveat and patent his invention or the means of borrowing it, that the only legitimate effect of such testimony is to discredit the whole defence by exciting the suspicion that it is bolstered up by exaggerated and unreliable testimony.

It will hereafter be shown that among the men with whom Drawbaugh maintained business and friendly relations during this period, there were many of intelligence and means. Some of them may have distrusted his judgment, and regarded him as a visionary. Some of them may have been indifferent or timid. But it is incredible that when only a trifling sum was required for a half interest in the invention, none of them could be sufficiently impressed with its merit or financial value, to investigate it seriously as a speculation or an investment. He induced persons to invest in faucet inventions, and in his magnetic clock; and it cannot be true that he could find no one to entertain the talking machine, which, according to the common rumor of the neighborhood, was to supersede the telegraph, and, in the words of one of the witnesses, "make Drawbaugh the richest man in the Cumberland Valley."

It was very natural that a hard-headed old farmer like William Darr, on being told by Drawbaugh that he had a machine by which he could talk across the Atlantic Ocean, should advise him to "try it first in talking across the Yellow Breeches Creek," but it is beyond comprehension or belief that none of the capitalists or speculators about him could be induced to seriously consider it, if it was an operative device.

DRAWBAUGH'S VERACITY IMPEACHED.

Where a witness falsifies a fact in respect to which he cannot be presumed liable to mistake, Courts are bound "upon principles of law, morality, and justice to apply the maxim *falsus in uno falsus in omnibus*." (The Trindad, 7 Wheat. 283.) Drawbaugh could not be mistaken in asserting that it was his poverty which prevented him from caveating or patenting his invention. He was not led to the assertion inadvertently. Those with whom he is associated in the defence understood fully, and so did he, that the fact that a professional inventor and patentee did not go to the Patent Office to secure an invention like the telephone for ten years after it had been completed and demonstrated, was almost conclusive against the theory that he had made the invention; and that unless this presumption could be parried, no Court would credit his story. The theory of constraining poverty was therefore formulated in the answer, elaborately fortified by witnesses, and testified to by Drawbaugh. It is overthrown by a few plain, indisputable facts, and Drawbaugh's veracity falls with it.

TESTIMONY OF CORROBORATIVE WITNESSES CONSIDERED.

The defence must rest upon the testimony of the witnesses who corroborate Drawbaugh. The case made by these witnesses is sufficiently formidable to overcome the legal presumption of the validity of the complainants' patents. It is met by the complainant with rebutting evidence direct and circumstantial, showing the intrinsic improbability of the theory that Drawbaugh was the inventor of the telephone, and showing his conduct or declarations inconsistent with any hypothesis that he was more than an unsuccessful experimenter with the invention. Many witnesses have also been produced by the complainant to attack the credibility and reliability of the testimony of the defendants' witnesses. Of necessity the testimony of most of the defendants' witnesses can only be attacked by showing that the witnesses are mistaken as to the time when they saw Drawbaugh's talking machine, or as to what they really saw on the occasions they refer to.

The way in which the testimony of Uriah P. Nichols is met will illustrate the general tenor of such testimony. Mr. Nichols was one of the most intelligent and trustworthy of the defendants' witnesses, a farmer and machinist, who testified that on the 18th day of January, 1875, he visited Drawbaugh's shop on business, saw two instruments, which he identified as Exhibits "B" and "A," and he described their mode of operation as stated to him by Drawbaugh at the time. He says he listened at one instrument while a boy spoke into another 200 feet away, connected by wires, and heard the boy say: "Is it you, father, speaking?" The complainant produces nine witnesses to show that the occasion could not have been prior to February, 1878. The witness fixes the date by a purchase of lime made by him on the visit, and states that he went to Drawbaugh's to see an electric clock of which he had recently read a description in a newspaper, and soon after the visit told Mr. Maish and others about the telephone he had seen at Drawbaugh's.

The complainant proves that the newspaper article was not published until February, 1878; that when the witness told Mr. Maish of the telephone at Drawbaugh's, the latter, who was then a member of Congress, remembered the occasion, knew all about Bell's telephone at the time, and had used it in Washington. Mr. Maish states that, as Drawbaugh was one of his constituents, he would have been deeply impressed by the conversation if he had understood Drawbaugh claimed to be the inventor. Without attempting to particularize the rest of the testimony for the complainant upon this issue, it suffices to say that several other witnesses were introduced to show that the lime was not purchased by Nichols before 1876. Much testimony is given by complainant upon collateral issues of a similar character.

One of these issues relates to the time when Thomas Draper ordered a hydraulic ram of Drawbaugh. Mr. Draper was an important witness for the defendants. He testified that he went with Mr. Kissinger, a tenant of his, to Drawbaugh's shop in May or the early summer of 1874, for the purpose of ordering of Drawbaugh a hydraulic ram to be used upon the farm Kissinger had leased of him in April, and that he was never at Drawbaugh's on any other occasion. He identified Exhibit "C" positively, and Exhibit "I" less positively, as the instruments used and through which he listened while Drawbaugh talked.

The complainant proved that the hydraulic ram was not put to use until the fall of 1878, and undertook to locate the date of Draper's visit approximately by that fact. Seventy-five witnesses were introduced by the respective parties upon this collateral issue. These illustrations show how hopeless a task it would be to review the testimony satisfactorily or analyze it minutely. Five hundred witnesses have been examined by the parties upon the main question and the collateral issues, and their testimony is in a printed record of over six thousand pages. If it were practicable to do so, it would not be profitable, because a microscopic view of the controversy would be inadequate and misleading.

LEADING FACTS IN THE CASE MUST GOVERN.

In cases where such a chaos of oral testimony exists, it is usually found that the judgment is convinced by a few leading facts and *indicia*, outlined so clearly that they cannot be obscured by prevarication or the aberrations of memory. Such facts and *indicia* are found here, and they are so persuasive and cogent that the testimony of a myriad of witnesses cannot prevail against them.

The first group of facts of this nature are those which bear upon the capacity and character of Drawbaugh as an inventor, and tend to show that it is not only highly improbable, but almost impossible, that he could have been the author of the telephone.

AUTOBIOGRAPHY OF DRAWBAUGH.

In the summer of 1878 he composed a biography of himself for publication in the history of Cumberland County, which presents a graphic picture of the inventor and of the man. He commences by describing himself as "born in the quiet, secluded village of Milltown, three miles from Harrisburg," and as "one of the greatest inventive geniuses of this age, who has spent the greater part of an active life conceiving and producing, as the result of the conceptions of an unusually fertile brain, a score of useful, ingenious machines and devices. It appears," he says, "by examining a list of his inventions, that the manufacturing interests of the place in his boyhood days gave direction to his thoughts and incentive to his actions." He proceeds to enumerate a list of his inventions as follows: "His first invention was

Digitized by Google

an automatic sawing machine; then a number of machines used in wagon making; then a machine for boring spoke tenets; then a machine for sawing tenets; a barrel stave jointing machine, patented in 1851 This machine was pretty generally introduced, and its merits appreciated; an automatic grinding machine was next invented to meet a demand created by the introduction of the jointer; then followed several machines for making stave headings and shingles, all of which were patented in 1855; after which, machines for rounding, heading, crozing, dressing and finishing outside of barrels were invented; these were again followed by device for running mill-stones; one for dressing mill-stones; a device for elevating grain in mills. He then invented and had patented four improvements in nail plate feeding; next a tack machine, and a new design in tacks. Photography next engaged his attention. He fitted himself for action in this field by manufacturing his own camera, ground and fitted acromatic lenses for camera, prepared the necessary chemicals, and improved the process for enlarging pictures. Next electricity and electrical machinery attracted his attention, and an electric machine was produced throwing out of consideration the galvanic battery and electric pile; then a machine for alphabetical telegraphing; then the justly celebrated electric clock, and the machinery necessary for its construction; and several kinds of telephones, one of which is operated by battery, and another by induction." He concludes as follows: "It will be seen from the foregoing that Mr. Drawbaugh has penetrated vast fields in search of information, and with what success we leave it to the readers to determine. We are proud to own Mr. D. as a citizen of our township, and deem him worthy of a position at the head of the list of our prominent men, and are happy to accord him that position." This portrait, drawn by himself, depicts without the aid of extrinsic evidence, the ignorance and vanity of the man, and incongruous and fantastic assortment of his inventive projects. It suggests, also, the character of a charlatan.

DRAWBAUGH NOT AN INVENTOR IN THE LARGE SENSE.

That he was a skilful and ingenious mechanic is undoubtedly true. Invention was his hobby and his vocation, but that he was an inventor in the large sense is disproved by the nature and results of his work. Every patent that he obtained was for some improvement on existing devices which involved mechanical skill rather than any high degree of inventive faculty. This is shown to some extent on the face of his patents, the list of which is as follows:

Nov. 11, 1851, "for improvement in stave jointing machines;" May 22, 1855, "for stave machines;" April 28, 1864, "for improvement in mill stones;" May 12, 1863, "for improved machine for leveling the faces of mill stones;" Dec. 12, 1865, "for improvement in nail plate feeders;" Nov. 20, 1866, "for improvement in faucets;" Nov. 19, 1867, "for improvement in nail feeding device."

His own testimony, given in an interference proceeding in the Patent Office in 1879, shows that none of his inventions were sufficiently meritorious to prosper vigorously. That proceeding involved a question of priority of invention between himself and one Hauck, respecting an improvement in a faucet. He had filed his application for a patent in January, 1879, and undertook to carry back the date of his invention to 1869. The scope and range of his inventive faculty became a subject of inquiry. He there testified that he had made "he might say fifty inventions, and had patented over a dozen." He was cross-examined respecting certain inventions to show that they did not work satisfactorily. He was then asked: "Since 1866 what machines have you conceived and perfected that have worked satisfactorily?" He answered: "To the best of my knowledge, I think they all have. The nail machine gave satisfaction. I had it running in the works, but the nailers drove it out. The tram and red staff was a good machine, and adopted by a number of millers. The magnetic clock I consider a good thing, but I am not through with experiments on it yet. I believe this last faucet to be a good thing."

If his nail machine had induced the workmen to drive it out of the shop, it ought to have commended itself to the capitalist. His magnetic clock had not been patented at this time, though it had been for a time the wonder and admiration of the community in which he lived; but when it was patented, in 1879, it was as a "new article of manufacture," consisting of a galvanic battery for electrical clocks, which had two old elements united instead of being disconnected as in former devices. The history of this clock shows clearly that it was of no practical merit; and the clock had been substantially described in Tomlinson's Encyclopedia, and he had the book before he made his alleged invention. His other electrical devices he never patented, and in his testimony in the interference proceedings he did not refer to them as among his perfected and successful inventions. One of these was his magneto-electric machine for short line telegraphing and fire alarms, sometimes mentioned as his "magneto key." It was not a new device, and the proofs show that it was a failure.

CHARACTER OF THE TELEPHONE INVENTION.

When the speaking telephone was first introduced to the attention of the scientific public, it was pronounced by one of the most eminent electricians of the day "a result of transcendant scientific interest,' and "the greatest by far of all the marvels of the electric telegraph." The inventions attributed to Drawbaugh include not only the conception of the principle of the unbroken, undulatory electric current, and of the delicate and complex instrumentalities essential to its efficient application in transmitting and reproducing articulate speech, but also of many other devices involving a nice adjustment of forces, and requiring sensitive mechanism. These were inventions of a peculiarly scientific order, which would seem to demand a special conversance with the principles of acoustics and electricity. Besides making the cardinal discovery of the theory of the unbroken, undulatory current, Drawbaugh is assumed to have perfected a brilliant and extraordinary series of original discoveries, for which, to use the words of Mr. Benjamin, "there is no parallel instance in the whole history of invention." Mr. Benjamin, referri g to the microphone, which was introduced to the public in 1878 by Mr. Blake, but which is one of the instruments asserted to have been invented by Drawbaugh at an earlier date, says: "It was looked upon as a great and original discovery."

THE LABORS OF BELL AND DRAWBAUGH CONTRASTED.

It was said by Chief Justice Taney (O'Reilly v. Morse, 15 How., 111), speaking of the invention of the telegraph: "No invention can possibly be made consisting of a combination of different elements of power without a thorough knowledge of the property of each, and the mode in which they operate on each other. For no man ever made such an invention without having first obtained this information, unless it was discovered by some fortunate accident." None of Drawbaugh's alleged discoveries were made by accident His statement is that starting with the belief that speech could be transmitted by electricity, he made first one contrivance and then another, gradually obviating difficulties and making advances experimentally, until he finally perfected the several inventions.

In view of Bell's special equipment for investigation and experiment in electrical and acoustic science, it would not seem strange that his persistent efforts to effect the electrical transmission of speech were eventually successful, were it not that others as intelligent, as well equipped, as ingenious, and as persevering as he, had devoted years to the same object in vain. He had the assistance of Mr. Watson, an expert in electricity and a skilled workman in electrical mechanism, in constructing the apparatus employed in his experiments, and who also aided him in his experiments. He had demonstrated his inventive proficiency by inventions in telegraphy, for which patents were granted to him. And yet, had it not been for an accidental discovery made by him in June, 1875, and which would probably have escaped one whose trained faculties were not centered on a careful study of the phenomena, he might have failed.

Drawbaugh, on the other hand, was not only untutored, but he was isolated by his associations and occupations from contact with men of advanced science; he had narrow opportunities for instruction, and few incentives for profound research. Among the multitude of his inventive conceptions was one that a talking machine was a possibility. According to the testimony of Lory, a witness for defendants, before Drawbaugh began his practical experiments, he exhibited a sketch of a machine that he was about to make that would talk a distance of twenty miles, and work something like a telegraph. If this is true, he commenced on his telephone as the architect plans a building, or the engineer makes a draught of his structure. His own testimony shows that he did not attempt to qualify himself for electrical inventions by any systematic study after he began experimenting with his talking machine. Although he had undoubtedly acquired considerable desultory information about electricity, and especially about the mode of operation and detail of construction of electrical mechanism, it is obvious that when he commenced with his talking machine he was a tyro in electrical science, essaying the most difficult work of the electrician. It is almost incredible that the subtle intellectual discoveries, which were a closed book to the ablest electrician, could have been reached by a smatterer in science, or by any series of empirical experiments.

MENTAL DEVELOPMENT OF INVENTION UNACCOUNTED FOR.

As has been remarked, he seems to have discovered nothing accidentally; yet, from the beginning to the end of his narrative, there is nothing to indicate the conceptive origin or the mental growth of the alleged invention. He presents a number of devices in the chronological order of their production, and testifies that he made one and then another and another, as experiments led him to modifications and improvements. He cannot describe what receiver or other apparatus he used with his first transmitter, and testifies: "I had a number of crude apparatuses,

Digitized by Google

but can't remember exactly the shape of any of them. I had membranes stretched over hoops—over a hoop—I remember that; and I had electro magnets, and the arrangement was varied; I don't remember exactly the arrangement."

He testifies that when he used the cup machine he used it in a continuous electric circuit, and thinks he used it as a receiver with Exhibit "B" as a transmitter. He states that he succeeded in transmitting speech with these two instruments, and, of course, he could only have done this by employing the unbroken undulatory current of electricity. He cannot state how he conceived the initial idea of the undulatory current and the continuous circuit, or subsequently the theory of any of the remarkable devices which he produces. His answers to questions intended to elicit such information may be illustrated by giving one of them: "I don't remember how I came to it; I had been experimenting in that direction; I don't remember of getting at it by accident either; I don't remember of any one telling me of it; I don't suppose any one told me.' He produces sketches, or models, or originals of instruments, which he says he made from time to time; he states that they were used to talk through on various occasions; and from these outlines of accomplished facts, leaves the history of his inventions to be filled out by inference and conjecture. An inventor can hardly forget the process of thought by which a great intellectual conception germinates and matures into the consummate achievement; but Drawbaugh's memory is a blank. If the untutored mechanic educated himself into an accomplished electrician by his own experiments and observations, the incidents and phenomena which revealed new discoveries and illumined the way for new advances would be indelibly impressed upon his mind. It seems a little short of the miraculous that a man of his capacity and equipment should have produced these inventions at all; more marvelous still that he should have produced them without any intellectual perception of his discoveries.

DRAWBAUGH'S STORY DISPROVED BY HIS OWN CONDUCT.

Another group of important facts, which are satisfactorily shown by the proofs, are those which indicate Drawbaugh's own knowledge that he was not an original inventor of the telephone. Reference has been made to some of the evidence bearing upon his neglect to patent or caveat his invention, in discussing the question of his credibility as a witness.

If no honest and reasonable explanation can be given for his conduct, the inference is very strong that he knew he did not have a practical telephone to patent. He may have had a talking machine, which was well calculated to excite the curiosity of the community in which he lived; he may have indulged in expectations that in time he could succeed in making a practical speaking telephone and reap fame and profit from it; but his conduct is almost decisive against the supposition that he had even deluded himself with the belief that he had produced anything sufficiently practical and valuable to patent. He never attempted to exhibit it outside of his own shop to prove that it would transmit speech at a distance of even a quarter of a mile. The proofs show that during all the years, from 1867 to 1878, he did not attempt to avail himself of opportunities for demonstrating his invention and bringing it to the notice of friends who were peculiarly qualified to appreciate, and were favorably circumstanced to assist him. One of these persons was a Mr. Kiefer, who resided at Harrisburg, from 1863 to 1881, and during that period had charge of the telegraphs of the Pennsylvania Railroad Company, and was a member of a firm whose business was the manufacturing of fine electrical machinery.

In 1873 he put up a fire-alarm system for that city. Drawbaugh made his acquaintance in 1874 or 1875, and brought his magnetic fire alarm to Mr. Kiefer for examination. At another time, he brought the works of his electric clock. He visited Mr. Kiefer on various occasions, obtained small supplies from him, and habitually conversed with him upon the subject of his electrical contrivances. The period of these visits begins just about the time when, according to the theory of the defendants, Drawbaugh had constructed Exhibits "E" and "D," and the invention was complete. He never mentioned to Mr. Kiefer the fact that he had experimented with a telephone. Mr. Wilson was superintendent of telegraphs for the Northern Central Railway Company, at Harrisburg, from 1864 to 1875. He was also mayor of Harrisburg. The company had an electrical workshop and supply establishment there for Mr. Wilson's department between 1871 and 1875. During this time Drawbaugh often came to the supply shop, and talked with Mr. Wilson about electrical experiments, and obtained parts of batteries, coils, magnets and other electrical material which the company had cast aside. He brought Mr. Wilson his electric clock and his magneto-electric key, and tried his machine for short line telegraphing at Mr. Wilson's office. He talked with him frequently about his inventions; but he never mentioned the telephone. His relations with David A. Houck were such that the latter procured him an opportunity to test his magneto key at the telegraph office of the railroad company at Mechanicsburg. Mr. Stees was the superintendent of a car company at Harrisburg, having shops in different parts of the city connected by telegraph lines. He was the first person to employ Bell's telephone on these lines, when they were introduced into Harrisburg late in 1877 or early in 1878. He was a friend of Drawbaugh, and Drawbaugh would naturally have applied to him if he wanted to test his telephone publicly and practically.

Isaac Lloyd was a school teacher and an alderman at Harrisburg; had known Drawbaugh long; was accustomed to visit his shop from time to time; saw many of Drawbaugh's inventions; was present on one occasion when Drawbaugh experimented with his magneto device for telegraphing at Mr. Wilson's telegraph office. Drawbaugh visited him frequently, and they were accustomed to converse about Drawbaugh's inventions. Drawbaugh showed him his dial telegraph, his electric fire alarm apparatus, and numerous other inventions. Witness assisted him about the electric clock. He was an owner of patents and a friend to whom Drawbaugh applied for loans, and was interested in mechanical subjects generally. The only mention ever made to him by Drawbaugh about a telephone was in 1878, when Drawbaugh told him he was experimenting with a telephone. From 1867, to July 1873, Drawbaugh was intimately connected with the persons composing the Drawbaugh Manufacturing Company, which was engaged in manufacturing devices under Drawbaugh's patents. He was a stockholder and the master mechanic of this company. Among the officers and stockholders were many men of capital and enterprise. There came a time when the managers of this company wanted Drawbaugh to suggest new devices for the company to manufacture. He never suggested the telephone nor attempted to induce the managers of that company to investigate or exhibit his talking machine. A number of the managers and employees of this concern testify that they never heard of the existence of the talking machine during the life of the company. Without attempting to refer to other testimony to the same general effect, what has already been referred to, shows that if Drawbaugh had seriously desired to bring his talking machine into public notice and secure the fruits of his invention, he had ample opportunity to do so. Who can doubt that if he had a practical telephone to exhibit, he would have selected just such men as Kiefer, Wilson, and the others to demonstrate it to them, and enlist them to demonstrate its utility and value to the public?

Such an invention was of a kind well calculated to excite public interest and to impress practical men with a quick appreciation of its commercial importance and its pecuniary value. It was so sufficiently perfected, according to the theory of the defence, that a patent could have been obtained prior to 1870, to secure the application of the principle and to compel every subsequent inventor to pay tribute to the discoverer of a new art. For years it was mechanically perfect, and its efficiency and importance as a great factor in human intercourse could have been demonstrated to the public without appreciable inconvenience or expense. Drawbaugh fully appreciated its importance and value. He had the means to patent it himself, and friends to assist him in introducing it into public use. He had the talent to induce others to invest in his inventions. No explanation is possible why, under such circumstances, his efforts should have left no mark upon the annals of inventive progress, and given no evidence of life beyond the idle curiosity his talking machine excited in the circle of his admirers during all these years. His conduct is more persuasive to show that he did not have a practical, operative telephone, than the testimony of a multitude of witnesses who may have seen and heard talking machines at his shop during this period. But the complainant has given evidence of his declarations, made by him, before he had any interest to pervert the truth, which afford a reasonable explanation of his conduct, and go far to explain how the testimony of the corroborative witnesses may be reconciled with the truth.

In 1874-6 Drawbaugh issued a business card, advertising himself as "Inventor, designer, and solicitor of patents." On the back of this card is printed a list of his inventions, as follows: "Stave heading and shingle cutter; barrel machinery; stave "jointing machine; tram and red staff for levelling face of mill "stones; rine and driver for running mill stone; nail machinery "for feeding nail plates; pumps, rotary and others; hydraulic "ram; the Drawbaugh rotary measuring faucet; carpet rag "looper; electric clock and magneto-electric machine for short- "line telegraphing and fire alarm, and propelling electric clocks." He takes pains to say of this magneto machine on his card that it "can be applied to any form of electric movement, and dispenses with a galvanic battery." He had obtained patents for some of these inventions, but had not for others. He was then experimenting with his electric clock, and with his magneto-machine for short-line telegraphing, fire alarms, etc., and included them in the list of his inventions. The omission to mention the most important one of all his inventions, one respecting whiich, according to his present testimony, there had not been a week from the time he made his first cup machine that he had not been engaged with it, one which was complete before his electric clock was complete, is a significant statement by implication that he had no such invention to advertise.

Digitized by Google

It is to be remembered that when he chronicled his achievements in the autobiographical sketch of 1878, the Bell telephone had been introduced into commercial use at Harrisburg, three miles from Drawbaugh's shop and the local newspapers had been full of the subject. The cursory allusion in that autobiography to "several kinds of telephones," is in striking contrast with the elaborate description of the electric clock, and wholly inconsistent with the theory that he deemed himself to be the originator of the telephone which, at that particular time, was a topic of universal interest.

In his testimony given in 1879, in the interference proceeding with Hauck, although he did not include the talking machine in the category of his successful inventions in the course of his testimony, he produced a sketch of his faucet, and stated that he made it "about 1874 to 1876, when I was experimenting on telephones or phonographs." He represented himself not as an inventor of that which he is now claimed to have perfected, but as an experimenter with a "telephone or phonograph." It is instructive to read this statement in juxtaposition with a statement made by him to Mr. Matthews in the preceding year. Mr. Matthews was the managing editor of the *Baltimore American*, and in April, 1878, made a visit to Drawbaugh at his shop to see Drawbaugh's magnetic clock, in consequence of information received from a correspondent. He was a careful observer, who went there obviously for the purpose of writing an article for his paper. That his memory is unusually retentive and accurate, and that he is a careful and conscientious man, is apparent from a letter written by him in December, 1883, after the proofs in the case had been closed, and in which he manifests a desire to correct certain errors of detail in his deposition. Upon that visit his attention was chiefly directed to the clock, but he examined Drawbaugh's other inventions, and conversed with him about them; and, among other things, conversed about the telephone. Drawbaugh's statement to him on that occasion was, that he had invented apparatus to send messages by means of an alphabet founded upon difference of sounds. He did not profess to be the inventor of the speaking telephone, or assert that he had ever transmitted speech successfully with his apparatus. He said that the idea of transmitting sounds in this manner was not new, and that he had read of it some years before in a publication translated from the French; and he denied Bell's right to claim the invention of the telephone, because of that publication.

In the article founded on that interview which Mr. Matthews subsequently wrote for publication in the *Baltimore American*, he adverts to the several useful agricultural, and mechanical devices patented by Drawbaugh, and adds: "It may be mentioned that Mr. Drawbaugh constructed a rude telephone long before Mr. Edison loomed up as the 'boss' inventor. He never expected to send articulate sounds over a magnetized wire, but he believed that an alphabet could be arranged after the manner of the musical scale, and that messages could be transmitted and understood by the variations of tone and pitch. This unlettered mechanic came very near anticipating Edison and Bell in the invention of the telephone, and nothing but his poverty prevented him from conducting his experiments to a successful issue."

His advertising card, his testimony before the Patent Office, his autobiography, and his statement to Matthews, authenticated in writing, were all made when he had no pecuniary interest to color the facts, and upon occasions when he was anxious to present himself in the most favorable light as an inventor; and they were all made after his talking machine, according to the theory of the defendants, was a perfect invention and known to be such by many of his friends and neighbors.

These are declarations evidenced in writing, and one of them made under oath, which point in but one direction. They are consistent with his conduct. They show that he understood himself to be an experimenter with telephones or phonographs, but not the inventor of the speaking telephone.

EVIDENCE OF COMPLAINANT'S WITNESSES CONSIDERED.

The complainant has supplemented this evidence by the testimony of other substantial witnesses who had favorable opportunities to know what Drawbaugh had invented, and who describe what they saw and did not see at his shop, and narrate what he said about his talking machines on various occasions. This testimony indicates that, at as late a period as in 1878-9, Drawbaugh was an experimenter, but not the author of the parent invention, nor one who had perfected any valuable improvement upon it; and is in substantial accord with his statement to Mr. Matthews and his testimony in the interference proceedings. What gives point and force to this testimony and parries the ordinary objections to the reliability of verbal declarations, is that these witnesses are persons who would have been forcibly impressed, because of their interest in the particular subject, by any assertion by Drawbaugh that he was an inventor of the telephone. During the time in question Drawbaugh had friendly relations with the newspapers of the vicinity; his friends were frequently communicating laudatory notices of his mechanical and inventive efforts to the press; and he himself visited one of the newspaper offices in the spring of 1878, to show a telephone he had made. These newspapers had published articles about the Bell telephone; but up to the spring of 1878. while many notices had been published in them about his electric clock and other inventions, describing him as a man of extraordinary genius, there had been no mention of the telephone; and when, in the spring of 1878, the subject was mentioned, he was referred to as one who was "inventing a telephone on a different plan from that now occupying the attention of the scientists," and as about completing "the new telephone he is now constructing."

In this connection it is to be noted that soon after telephones were introduced in Harrisburg, late in 1877, or early in 1878, Drawbaugh visited the offices where they were used, examined the inside of the instruments, and borrowed one to take home, which he kept for several days; and the instrument which he borrowed bears a close resemblance in appearance to Exhibit "A," which it is asserted he had made in 1873 or 1874.

No extended reference will be made to the testimony of other witnesses, such as Mr. Weaver and Mr. Grissinger, showing declarations of Drawbaugh made after the Bell Telephone was in commercial use to the effect that, although he had experimented on the telephone years before Bell, he had obtained no satisfactory results.

EFFECT OF TESTIMONY FOR DEFENCE DISCUSSED.

It remains to consider what effect is to be given to the testimony of the multitude of witnesses who have been produced to substantiate the defense. Disregarding the testimony which is merely hearsay, and therefore incompetent as evidence of the main fact, the testimony of many other witnesses is overthrown by the palpable improbability of their statements, or by the contradictions between their statements and those of other witnesses for the defendants upon substantiative points, or by successful attacks upon their accuracy in the rebutting testimony of the complainant.

There still remains a formidable number of witnesses who testify to seeing or using Drawbaugh's talking machine, and some of whom identify particular exhibits as the instruments which they saw or tried.

No doubt is entertained that Drawbaugh was experimenting at an early period with telephones or phonographs. He knew about the phonographs or phonautograph of Scott as early as in 1863. The membrane diaphragm excited by sonorous waves, and the mechanism of the phonograph were not novelties, and, among the diversity of inventive possibilities had probably attracted his interest. Prior to the issue of Bell's patent, Dr. Van DeWeyde had made public experiments with the Reis telephone at the City of New York, and others had made like experiments elsewhere. In May, 1869, a full description of the instrument and of the experiments was published in the newspaper, "*The Manufacturer and Builder*," treating it as a highly interesting curiosity, which contained the germ of great practical purposes. Whether other newspapers noticed the experiments or not is not shown, nor is it shown that Drawbaugh saw the article in "*The Manufacturer and Builder*." It would be difficult to prove the circumstances if he did see it. Some such publication probably stimulated him to experiment. If he made a sketch of the mechanism at the start the material for it was at hand. As is stated by Mr. Benjamin, it has been asserted of the Reis instrument, that certain sounds of the human voice can be transmitted by it, but in truth these are merely fragmentary reproductions of vocal sounds, and the transmission of articulate speech could not be effected because it was constructed on the make and break principle, instead of on that of the undulatory unbroken current.

It is not strange to any reader of the autobiography that Drawbaugh should have taken up the telephone. That he and those about him should have treated it as a talking machine is entirely natural. That his talking machine as late as in 1876 bore a striking resemblance to the Reis telephone is shown by Mr. Shapley's testimony, a witness who noticed the resemblance and loaned Drawbaugh a copy of the *Scientific American* describing it.

There is enough here to explain Drawbaugh's declarations to his neighbors about the talking machine he was inventing, and to excite the curiosity of the community. A careful reading of the proofs renders it easy of belief that the witnesses who testify about casual visits to his shop, which occurred many years before their testimony was delivered, and to cursory tests of his instruments on those occasions, have confused the fragmentary and incoherent articulation of such an apparatus with the hearing of distinct words and sentences. When witnesses undertake (as many of them do), to give the exact words or sentence heard in the instrument five or ten years before, when their attention was not called to the subject afterwards, no hesitation is felt in rejecting such statements as utterly incredible. It may be charitably inferred that such a witness has confused his recollection with more recent impressions. As will hereafter be shown, the proofs demonstrate that most of the witnesses who testify to having heard distinctly and coherently through the talking machine, all those who indicate the Exhibits "B." "F," and "C" as the instruments, are mistaken if they are truthful. If Draw-

Digitized by Google

baugh was a charlatan, he may have assisted in deluding them; and the proofs show, that between 1872 and 1874, a string telephone was in his brother's shop, in the village. The fact that he never attempted to exhibit his machine outside of his shop where it could be used between points some considerable distance apart, and where its real capacity could be readily observed, is significant in this connection.

The more important testimony is that by which it is sought to identify the several exhibits, and show their existence at times consistent with the theory of the natural evolution of the invention. The identification of particular exhibits as seen by the witnesses among the various objects of curiosity at Drawbaugh's shop several years before they testify, is necessarily unreliable when it is attempted by observers who had no knowledge of the mode of operation or of the internal organization of the instruments. Such witnesses could not appreciate what they saw even if they examined the instruments. Most of the witnesses belong to this class. Indeed, the greater proportion of them do not profess to identify the exhibits positively. Some are more certain than others that particular exhibits are the instruments they saw. Exhibits "F," "B," and "C," are fragmentary remains of instruments, and their value depends upon Drawbaugh's description of the operative parts that no longer exist. Scores of witnesses testify to seeing the tumbler device resembling Exhibit "F," and the tin can device resembling Exhibit "B," but the identification of the other exhibits prior to the date of Bell's patent is comparatively feeble.

The appearance of Exhibits "F," "B," and "C" is sufficiently peculiar and distinctive to impress the memory of those who saw them. On the other hand, the other exhibits are not of this character, and all that ordinarily the witnesses can safely say of them is, that five years or more before testifying they think they saw or used a small walnut box externally resembling "I," or "A," or "E," or "D."

It may be said generally of all the testimony of the witnesses who attempt to identify exhibits, that it is mainly valuable when it proceeds from those who used the instruments which they think they remember and obtained results. They must remember the results obtained much better than the minor differences of appearance presented by the instruments Granting that Exhibits "F," "B" and "C" would be likely to be remembered, what shall be said of the value of the testimony of scores of witnesses who state that they tested these instruments, or saw others test them, and they articulated perfectly, when it appears by the most authentic test that these instruments were incapable of such articulation?

RESULTS OF TESTS OF DRAWBAUGH'S APPARATUS.

In March, 1882, after most of the proofs in the case had been taken, a test was made of the capacity of the exhibits to transmit speech in the presence of the counsel and the experts for the respective parties. It is not accurate to say a test was made of the exhibits; but reproductions of "F," "B," and "C," were made by Drawbaugh and as rehabilitated by him, were used for the test. Whether these were honest reproductions, no one can tell; but such as they were, they were experimented with by Drawbaugh before they were subjected to the test. Whatever else that test demonstrated, it proved that articulate speech could not have been practically communicated through Exhibits "F," "B," and "C," at Drawbaugh's shop under similar conditions; and that only fragmentary or incoherent speech could be occasionally and exceptionally rendered by the reproduced instruments which had been experimented with privately before the public test. The proofs show that all along to 1878 Drawbaugh exhibited his earlier instruments, "F" and "B," to spectators and used them as his talking machine, sometimes showing or using both together, and sometimes one of them. The testimony of the defendant's witnesses,—Springer, Moore, Musser, and Bayler, is pertinent upon this point, and has been referred to. How is it to be explained that he used these crude instruments in 1875 and 1876, as his talking machine, if he had the better instruments, especially such instruments as "E" and "D"? But in view of the fact now shown that these earlier exhibits are incapable of satisfactory articulation, what confidence can be placed in the rest of the testimony produced to identify exhibits? If the witnesses are mistaken in identifying these very characteristic instruments, and in recalling the results obtained through them, little reliance can be placed upon the identification of the other instruments, or upon the statement of the results which the witnesses think were obtained through them. If these witnesses are mistaken in the dates which they fix for the occasions they speak of, their testimony can be reconciled with all the probabilities of the case. And the reasonable explanation of their testimony is, that those witnesses who really saw or used the later exhibits, did so in 1876, 1877, 1878, and later, instead of on earlier occasions.

DRAWBAUGH AN EXPERIMENTER, NOT AN ORIGINAL INVENTOR.

The proofs on both sides lead to the general conclusion that Drawbaugh was not an original inventor of the speaking telephone, but had been an experimenter without obtaining practical results until the introduction of the instruments into Harrisburg. It is very probable that after reading in the *Scientific American*, loaned to him by Mr. Shapley in October, 1876, the article purporting to describe Bell's telephone, but which really describes better the Reis apparatus, he undertook to improve his old devices. At that time, or after he had examined the telephone instruments at Harrisburg, and carried one of them home to study, he may have altered the organization of his instrument, and made the intermediate exhibits between "F" and "D." If he exhibited them at his shop, and was able to transmit speech through them, this fact will account for the testimony of the witnesses who identify these exhibits, and may be mistaken as to the time they saw them. The real history of his talking machine is known only to himself, and it will not be profitable to conjecture when he made the advanced instruments which he claims to have made in February, 1875, and the later instruments.

It may be, that in discrediting his narrative, and rejecting the theory of the facts which rest upon it, the value of the corroborative testimony has been underestimated. However this may be, no doubt is entertained as to the conclusion which should be reached upon the proofs.

SUMMARY OF DEFENDANT'S CASE.

Succinctly stated, most favorably for the defendants, the case is this: One hundred witnesses, more or less, testify that on one or more occasions, which took place from five to ten years before, they think they saw this or that device used as a talking machine; they are ignorant of the principle and of the mechanical construction of the instruments, but they heard speech through them perfectly well, and through one set of instruments as well as the other. This case is met on the part of the complainants by proof that the instruments, which most of the witnesses think they saw and heard through, were incapable of being heard through in the manner described by them, and further that the man who knew all about the capacity of his instruments never attempted to use them in a manner which would demonstrate their efficiency and commercial value, but on the contrary for ten years after he could have patented them, and for five years after they were mechanically perfect, knowing all the time that a fortune awaited the patentee, and with no obstacles in his way, did not move, but calmly saw another obtain a patent and reap the fame and profit of the invention.

TRUTH OF THE DEFENCE OPEN TO FATAL DOUBT.

Without regard to other features of the case, it is sufficient to say that the defence is not established so as to remove a fair doubt of its truth, and such doubt is fatal.

The observation of an eminent commentator may be quoted as apposite to the case: "No form of judicial evidence is infallible, however strong in itself; the degree of assurance resulting from it amounts only to an indefinitely high degree of probability; and, perhaps, as many erroneous judgments have taken place on false or mistaken direct testimony, as on presumptive proof." Best's Ev. Sec. 468.

A decree is ordered for complainant.

REVERBERATIONS FROM THE TELEPHONE DECISION.

The motion for an injunction made by the Bell Telephone Co., against the People's Telephone Co., was renewed in the United States Circuit Court at Trenton, N. J., Dec. 15. When it was originally made several months ago, the court refused it, but gave permission for it to be renewed at any future time. It was urged that the recent decision of the main question justified the granting of the desired injunction. The counsel for the opposing company declared that this was not a final decision of the matter. This is a distinct company from the one which has been engaged in exploiting Drawbaugh, and employs the Hopkins telephone. Judge Nixon reserved his decision.

The United States Telephone Manufacturing company, of New York, and the McDonough Telephone and Telegraph company, of New Jersey, filed a bill in the United States Circuit court at Trenton, Dec. 22, asking for an injunction against the American Bell Telephone company, of Boston, and the Domestic Telegraph and Telephone company, of Newark, for an infringement of certain patents of James W. McDonough of Chicago, Ill., for electric speaking telephones.

THE ELECTRIC RAILWAY SYNDICATE.

The fifth of the series of meetings for the purpose of uniting the different electric railway interests was held in this city December 16. It was decided that all the parties who are to come into the American Electric Railway Co., must agree to transfer to that company all their patents and inventions for electrical propulsion on railways in the United States, as a condition precedent to participating in the advantages of this arrangement, they to be compensated by participation in the stock reserved for patents and inventions, in the proportion fixed by the arbitrators.

Digitized by Google

Sir William Thomson, of Glasgow University; Prof. Charles R. Cross, of the Massachusetts Institute of Technology, and President Harris, of the Northern Pacific Railway, have accepted invitations to be members of the Expert Commission to test the rival electric motors on the Second avenue elevated railway, and apportion the stock of the new company among the companies consolidating, according to the value of their respective motor patents; and it is believed that President Roberts, of the Pennsylvania Railway, and President Rutter, of the New York Central Railway, will also accept. It is understood that the commission will be empowered to employ expert electricians and practical mechanical engineers to conduct the test, under its direction, and its members will render a verdict upon the results of the experiments.

At a subsequent meeting held Dec. 22, it was decided to issue an invitation to all reputable holders of patents relating to the subject of electric railroad propulsion, to assign the exclusive rights under their several patents for electric railroad purposes to the new company, and to receive from the board of arbitration their proportionate share of the stock according to the value of such patents. Those who do not avail themselves of the offer before December 31 are to be excluded from the advantages of the arrangement.

STATE TAXATION OF TELEGRAPH COMPANIES.

Under the corporation law of New York state passed in 1881, the Controller desires to levy a tax on the entire capital stock of the Western Union, the Gold and Stock, and other telegraph companies. The companies are resisting the payment of the tax, arguing that only that proportion of their property represented by stock in this state should be taxed. The Gold and Stock Telegraph Co., makes the point that the State has no right to tax property not within its limits, as it would do if it taxed the entire capital stock of the company. In the lower courts the judges have decided against the companies. Nearly $500,000 is involved in the two cases.

General Wager Swayne and Matthew Hale appeared for the telegraph companies and Attorney-General O'Brien for the people. General Swayne claimed that by a law passed in 1853 telegraph companies should be taxed only on that part of their capital covering property in this state. This law was not repealed by the corporation tax law of 1881. In his brief he quoted from many authorities. The Attorney General in his reply argued that the law of 1881 already gave the State the right to tax all the capital stock and that the act of 1853 was repealed by that of 1881. The judges, as usual, took the briefs and reserved their decision.

DISSOLUTION OF THE TELEGRAPH POOL.

The pooling arrangement under which the Bankers and Merchants' and the Postal Telegraph companies have been doing business since the retirement of the Baltimore and Ohio Telegraph Co. from the celebrated tripartite agreement, was dissolved December 11 by mutual consent as well as by necessity. The Bankers and Merchants', although in a receiver's hands, has been in great financial distress. It is stated that a complete separation of business interests at stations where the offices of the two companies have been mutually conducted will be arranged within a few days.

The receipts of the Bankers and Merchants' Co. have not been sufficient to enable the receivers to meet the interest due on the large bonded debt. While the employés have waited months for their pay, business has been falling off, until the hopelessness of struggling to maintain the united lines was apparent.

PRINTING TELEGRAPH PATENT SUIT.

Before the U. S. Circuit Court at Hartford, Dec. 23, Judge Shipman on the bench, a hearing was had on a motion for a preliminary injunction in the case of the Gold and Stock Telegraph Co. against the Commercial Telegram Co., in a suit concerning the right to use the Field printing instrument, it being claimed that this is an infringement upon the patents of E. A. Calahan, owned by the complainant company. Dickerson, Thurston and Dickerson appear for the plaintiff, and Roscoe Conkling and General S. A. Duncan for the defendant.

AUTHORIZED TO ISSUE RECEIVERS' CERTIFICATES.

Counsel for the Receivers of the Bankers and Merchants' Telegraph Co., made application to the United States Circuit Court to have confirmed an order made by the Supreme Court of New York permitting the Receivers of that company to make a settlement with the Receivers of a construction company which had constructed property for the telegraph company. Under the arrangement the Bankers and Merchants will receive the property so constructed, and issue Receivers' certificates in payment therefor, which will be secured by a lien on the property in question. Judge Butler confirmed the order on Dec. 9th, so far as issuing Receivers' certificates to the amount of $130,000, but refused permission for the issuance of $20,000 worth additional which had been asked for.

ELECTRIC LIGHT AND POWER.

Domestic.

Easton, Penn., is lighting its streets with electricity.

At a recent public meeting at Toronto, Mr. James French said that "the electric light which we were promised would be cheaper than gas, was about three times as expensive."

For some weeks Delaware avenue, between Market and Vine streets, Philadelphia, was in almost total darkness, as the electric lights were not lighted. The cable is laid underground, and it is said the insulation was burned off in places. Finally Mayor Smith instructed the police to light the gas lamps, which was done, and it is said will be continued until further orders.

The electric lighting apparatus on the dome of the court house, at Wabash, Indiana, was wrecked on the night of October 22d, by a flock of wild geese.

The prospects are that Laconia, N. H., will soon be furnished with electric lights. A preliminary meeting has been held and $1,500 in stock subscribed, and upwards of 100 lights engaged by merchants and others. Local parties are interested in the enterprise. They have secured excellent power and expected to have the lights in operation December 20.

The managers of the New Orleans Exposition have awarded the following contracts for lighting the buildings and grounds: The Leavitt-Mueller electric light, 800 arc lamps for the main buildings; the Brush electric light, 300 lamps for the Government and State exhibit building; the Jenney arc light, 100 lamps, with five iron towers for the grounds and the live stock department; Thomson-Houston, 100 arc lights for the machinery, extension and saw mill; Edison incandescent light, 4,800 lights for the Music Hall, Horticultural Hall, the Art Gallery, State head-quarters, and offices. Each principal entrance and wharf will be lighted by six Leavitt-Mueller lamps; altogether 1,500 h. p. is required for the electric lights which cost the Exposition over $100,000.

A corporation has been formed under the laws of Massachusetts, entitled the Holyoke Electric Light and Power Co., Wm. A. Chase, Pres., R. C. Winchester, Treas. Capital $10,000.

A company has been formed in Bangor, Maine, with a capital of $50,000 for establishing a central lighting station to supply the city and people there with arc and incandescent electric lights, as well as electric motors for transmission of power.

The Brush Electric Light works, at Toledo, O., were damaged by fire on November 19th to the extent of $10,000.

Foreign.

An Electric Lighting company has lately been formed in Madrid, with a capital of £102,000, for the purpose of establishing in that city a central station, from which 12,000 incandescent lamps may be supplied. The works, to be erected near the Puerta de Salamanca, will comprise 15 Belleville or de Naeyer 100 h. p. steam-boilers, and two Sulzer or Corliss engines of 1,000 h. p. The electric machines to be erected are two Gordon dynamos, which will supply 10,000 ampères with an electromotive power of 120 volts. The current is to be distributed by means of underground cables in accordance with Edison's system.

The British Gaslight Co. has given the Town Council notice of its intention to raise the price of gas in its Hull district on and after the 1st of January. This step, attributed to the discontinuance of the electric lighting, has given much dissatisfaction. A special committee has been appointed to consider it.

A meeting of the Edison and Swan United Electric Light Co. (Limited) was held, November 11, in London. Mr. J. S. Forbes presided, and in the course of his remarks said that, including the item of depreciation, £2,310, the loss on the year's operations had been £28,214. They had had, roughly, £300,000 locked up, to represent which they had their patents, a first-rate manufactory, and a trained establishment. For the first three months of the current year's operations there had been a balance of profit of £752, or at the rate of £3,000 a year. It was their intention to do no more speculative business, either street, house to house, or any other lighting, but only that which paid.

The status of electric lighting in Australia, is given by Mr. McLean of Melbourne as follows:

Of the electric light there is very little to be said. Some efforts have been made, especially in Elizabeth street, Melbourne, one of our principal streets, but it was not a success, and all efforts on a large scale have been abandoned. There are a few lights kept

Digitized by Google

going in some of the theatres, but what it costs I cannot say, except that I believe that the managers will not pay more for it than they have to pay for gas, and so I presume it is kept on there as a kind of standing advertisement. The belief in the colony is the same as that in England, viz., that electricity as a light is only yet in its infancy, and with this conviction there does not seem a disposition to help the problem forward

The Great Eastern before leaving England for the New Orleans Exposition, is to be fitted up throughout with incandescent lamps.

MANUFACTURING AND TRADE NOTES.

The Westinghouse Machine Co., of Pittsburg, has received an order from Scotland for a steam-engine for use in one of the ironclads of the British Navy. It will operate the electro-dynamo on each ship from which light is obtained for incandescent lamps throughout the vessel, arc lights for signal or danger lights, and the enormous search light at the masthead.

The Electrical Supply Co., of Ansonia, Conn., has opened an office and wareroom at 175 Lake street, Chicago. A full line of electrical goods, such as electrical wire, carbons and general supplies, will be kept in stock.

MISCELLANEOUS.

The Underground Electric Co., with a capital of $25,000, has been incorporated in New York by Joseph B. White and Henry Franz.

The Sims Electric Torpedo Co. has been incorporated in New York with a capital of $1,000,000. The corporators are Oscar Marshall, Henry P. Butler and Richard C. McCormick. Their purpose is to manufacture torpedoes, torpedo boats, submarine vessels, war ships and other materials of war.

The following electrical companies have been incorporated in Illinois: The Illinois Pan-Electric Co., capital stock, $1,000,000; incorporators, Porter White, John Boyle, and L. M. Chipley. The Globe Electric Engineering Co., capital $200,000; incorporators, Herbert A. Streeter, proprietor of the Globe Iron Works; Henry Burkholder and George W. Wilbur.

The American representative of Marcus Ward & Co., British paper manufacturers says: "An experience of twenty-five years in the manufacture of paper has convinced me that climate has much to do with the quality of fine writing papers. You may have as good mills and workmen as England, but your climate changes so suddenly and violently that the greatest care in the process cannot provide, say, for the different amount of sizing that must be put in the pulp, and that varies with the weather. Every English workman in an American paper or cotton mill will tell you that the electricity in the air in this country is much more intense than it is over the water. So much so, indeed, that special apparatus is made to correct its influence about a machine. English writing paper is largely used in the United States. In Washington I supply the various departments and the White House with our paper."

PERSONAL MENTION.

Hon. George Walker, who was appointed Consul General to France under the Hayes administration, is now in this country. He was formerly a vice-president of the Western Union and more recently of the Gold and Stock Telegraph Co.

A press despatch from Washington says that "It is probable that Mr. H. D. Lyman, Second Assistant Postmaster General, will resign his office within a short time to accept a position with the Bell Telephone Co."

THE TELEGRAPH.

The war of rates was inaugurated in the interior of New York state last month by the Baltimore and Ohio company reducing from 25 to 20 cents to points within the state.

Minneapolis has a district telegraph system which has some peculiar features. It does a general parcel, package and trunk delivery business, keeping several wagons constantly employed. This began in a small way by employing boys to carry bundles. The business men in the retail line found them very useful in the delivery of purchases to customers, and at length the work became so large in volume that the use of teams was necessary.

A larger business is done by telegraph companies in the United States than in any other country in the world. Over 40,000,000 messages were sent last year. Great Britain sent nearly 33,000,000, France 26,000,000, and Germany 18,000,000. The total for the world was 153,000,000, fully one-half being sent in English-speaking countries. Germany has nearly as many telegraph offices as the United States, although so much smaller in area, and doing less than half the business. Great Britain, on the contrary, does a large business with comparatively few offices.

The Houston and Texas Central Railway Co., applied to Judge Hartley, of the Texas State Court, for an injunction against the Baltimore and Ohio Telegraph Co., to restrain that company from constructing its lines on the right of way of the railway company in Collin County. Judge Hartley refused the injunction, and the telegraph line upon the right of way of the railway company is completed.

The local telegraph service within the Paris fortifications was to be performed entirely by pneumatic tubes after December 15th.

In the United States Circuit Court at Norfolk, Va., Dec. 5th, Judge R. W. Hughes presiding, a bill was filed by William Mahone, suing for himself, and others similarly situated, as a bondholder and stockholder of the Southern Telegraph Co., charging fraud, waste, mismanagement, and insolvency on the part of the officers of said company, and praying for an injunction, the appointment of a receiver, and the winding up of the company. The litigation involves bonds amounting to $2,500,000. A temporary restraining order was granted by the court, the Marshal was ordered to take custody of the affairs of the company, and the case was set for further proceedings on Dec. 19. It is stated that the franchise of the company is a valuable one, and under proper management it could be made not only solvent but profitable. The company is in default for interest, and, it is said, in danger of irreparable bankruptcy.

FINANCIAL.

Sheriff Johnson sold at public auction, at Petersburg, Va., Dec. 19, $19,500 of the Southern Telegraph Company's bonds, of the denominations of $1,000, $500 and $250, at the rate of $17 per $100.

The Western Union directors met December 10 and adopted the following report of the Executive Committee:

The following statement will show the condition of the company at the close of the quarter ended September 30, 1884:

Surplus July 1, 1884, as per last quarterly report		$4,157,468 89
Net revenues quarter ended September 30, 1884		1,545,529 17
		$5,702,998 06
From which, deducting appropriations for—		
Dividend of 1¼ per cent., paid October 15	$1,399,807 49	
Interest on bonded debt	124,000 00	
Sinking fund	20,000 00	
		1,543,807 49
Leaves a surplus, October 1, of		$4,159,190 57
The net revenues of the quarter ending December 31, instant, based upon nearly completed returns for October, partial returns for November, and estimating the business for December, will be about		$1,500,000 00
Add surplus October 1, as above		4,159,190 57
		$5,659,190 57
From which, appropriating for—		
Interest on bonded debt	$124,000 00	
Sinking fund	20,000 00	
		$144,000 00
Leaves a balance of		$5,515,190 57
It requires for a dividend of 1¼ per cent. on the capital stock		1,199,837 00
Deducting which leaves a surplus, after paying dividend, of		$4,315,353 57

In view of the preceding statements, the committee recommend the adoption by the board of the following:

Resolved, That a dividend of 1¼ per cent. on the capital stock of this company be hereby declared, payable on and after the 15th of January next, to stockholders of record at the close of the transfer books on the 20th of December, instant.

Resolved, That for the purpose of the dividend hereby declared, the stock books of the company in New York and London be closed at 3 o'clock on the afternoon of the 20th of December, instant, and be reopened on the morning of the 2d of January next. NORVIN GREEN, President.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER *by* Pope & Edgecomb, *Solicitors of Patents for Electrical Inventions*, 59 *Wall Street, New York city.*

LEGAL NOTES.

Supreme Court of the United States.—The case of *Butterworth*, Commissioner of Patents *v. The United States ex rel. Hoe et al.*, decided November 3rd, 1884, involves important questions as to the right of appeal from the decision of the Commissioner of Patents to the Secretary of the Interior. The history of this case is briefly as follows:—A patent was granted to one Scott,

Digitized by Google

March 18th, 1881, for a printing machine. An application was filed by one Gill, March 12th, 1881, for a similar invention. An interference was declared between Gill and Scott, which was heard by the Examiner of Interferences and decided by him in favor of Scott, and on appeal to the Examiners in Chief, the decision was affirmed. An appeal was taken to the then Commissioner, Marble, who, after argument, decided the case in favor of Gill. No motion either for a new trial or a rehearing was made before the Commissioner, but an appeal was taken by Scott to the Secretary of the Interior. While the case was pending before the Secretary, counsel for Gill made a demand upon the present Commissioner, Butterworth, for a patent to issue, based upon the decision of Commissioner Marble that Gill was the first and sole inventor. Commissioner Butterworth refused so to issue the patent, whereupon Gill, through his counsel, filed a petition for a writ of mandamus against the Commissioner to compel him to issue a patent to Gill in accordance with the judgment of his predecessor.

A rule was made requiring the Commissioner to show cause why the writ should not issue against him as prayed for. In answer to the rule, the Commissioner reviewed the history of the case, admitted that a judgment in favor of Gill had been entered in the interference between him and Scott, which was unreversed, and that no motion or other proceeding was pending in the office to review or modify that finding. The Commissioner further stated that he did not desire to hear further argument in the case, nor to make any other or additional inquiry or investigation in that behalf; that he refused to issue the patent on the sole ground and for no other reason than that the case had been appealed to the Secretary of the Interior; that if the honorable Secretary had jurisdiction to hear and determine the case on appeal, refusing to issue the patent as demanded by Gill was proper, otherwise it was not, and Gill was entitled to have his patent issue to him as prayed. Upon this return issue was joined. The case was heard by the Supreme Court of the District of Columbia, and a writ of mandamus against the Commissioner awarded. The case was then taken on appeal to the Supreme Court of the United States. The Supreme Court held that mandamus will not lie to compel a public officer to do a particular thing which his superior in authority has lawfully ordered him not to do. The court also held that in all matters in which the action of the Commissioner is judicial or quasi-judicial, the fact that no appeal is expressly given to the Secretary is conclusive that none is to be implied, and this is equally true whether or not an appeal is allowed to the courts; that the supervision conferred upon the Secretary by the statute does not authorize him to substitute his discretion and judgment for that of the Commissioner when by law the latter is required to exercise his own, and when that judgment, unless reversed in the special mode pointed out by judicial process, is by law the condition on which the right of the claimant is declared to depend. *Morris et al.* v. *McMillin.* This was an appeal from the Circuit Court of the Western District of Pennsylvania. The original bill was filed to restrain appellants from infringement of patent dated April 16th, 1867, for an improvement in applying steam-power to the capstans of steamboats. The Supreme Court reversed the decree of the Circuit and remanded the case with directions to dismiss the bill, on the ground that the patent was void for want of patentable invention, the only field of invention left for the patent to cover being the application by the old and familiar arrangement of shafts and cog-wheels of the power of an auxiliary engine to a capstan instead of a windlass.

United States Circuit Courts.—*Odell et al.* v. *Stout et al.* Suit for infringement brought in the Southern District of Ohio, alleging infringement of reissued patent for roller-mills. SAGE, J., held, MATTHEWS, J., concurring, that the grant of a reissue is *prima facie*, but not conclusive evidence of inadvertence, accident or mistake. Claims in the reissue for patentable parts of the combination in the original, do not invalidate the reissue if the patentee is first inventor of the patentable parts claimed, although the original was for the combination alone; therefore a patentee may under proper circumstances extend his claims by reissue to the limits of his invention, but he may not enlarge the invention. Upon the authority of *James* v. *Campbell*, and other decisions of the Supreme Court, it is clear that the claim may be enlarged by reissue if the patentee moves promptly and no rights of others have intervened. What constitutes a reasonable time must be decided by the Court upon the case presented. The rule is equitable and therefore flexible and to be applied according to equity. The rule that an invention may be exhibited either in a drawing or model so as to lay the foundation of a claim for priority, is to be taken with the qualification that it must be followed up with reasonable diligence. Patents granted between the making of a drawing by complainant and his filing an application a year afterward, are not anticipated by such drawing. One claim in a reissue may be void without necessarily invalidating other claims, provided the latter were made in good faith. Where it appears that reissued claims were intended to broaden the invention and thereby cover intermediate inventions, the fraud may be sufficient to vitiate all the claims. *Hatch* v. *Adams.* This was a case in the Eastern District of Pennsylvania, involving a single question, viz.: Has a purchaser of patented articles from a grantee that has an exclusive right to manufacture and sell under the patent in a specified part of the United States, the right to sell the articles in the course of trade outside the designated limits of the grant? MCKENNAN, J., decides this question in the negative.

United States Patent Office.—In *Gill* v. *Scott*, a rehearing was asked for by counsel for Scott. The state of facts in this case is set forth in the report of the decision of the U. S. Supreme Court given above. After the rendition of the judgment of the Supreme Court of the District of Columbia, but possibly before the opinion of the Supreme Court of the United States was announced, counsel for Scott moved for a rehearing on the record. BUTTERWORTH, Commissioner, says that after a case has been heard and decided by the Commissioner it is competent for either party to move for a rehearing on the record. When, however, instead of making such motion the party prosecutes an appeal; Held, that the prosecution of such an appeal operates as a waiver of the right to subsequently make such motion. Also, the case having been decided by a former commissioner, it would be obnoxious to rule 139 for the present Commissioner to rehear it, no new facts having been presented to him. The motion was accordingly overruled. In *ex parte Wilkin*, which was an appeal from the primary examiner, who objected to the language of applicant's claim on the ground that it was vague and did not identify the construction which performed the result desired, referring to *ex parte Deming* (26 O. G., 1,207), and *ex parte Holt* (29 O. G., 171), Acting Commissioner DYRENFORTH held that a claim which mainly depends upon such language as "mechanism, substantially as described" to define the invention sought to be patented, is vague and indefinite and does not comply with the statute. In *ex parte Chapman*, it appeared that the last action of the Patent Office in applicant's case was made August 28th, 1882, which therefore became abandoned on August 28th, 1884. The applicant now petitions to be allowed to renew the application under the provisions of section 4,894 R. S. It appeared that applicant's attorneys, who reside in Chicago, put the case into the hands of their Washington associate on August 18th, and that an amendment was prepared by him before the two years expired, but was not filed in time because of his absence from the city. BUTTERWORTH, Commissioner, denied the petition, on the ground that the discretion vested in the Commissioner by the statute is judicial discretion and not mere complaisance, and hence satisfactory evidence must be adduced that the delay could not have been avoided, which in this case did not appear. *Ex parte Lassells.* This was an appeal from the action of an Examiner who refused to accept an amendment cancelling all the claims of an applicant without substituting others. The Examiner held that the cancellation of all the claims, being in effect an abandonment, should be framed in such manner as to make that intent clear. BUTTERWORTH, Commissioner, held that while the question is not free from doubt, claims would seem to be indispensable to the life of the application. The cancellat on of all claims signifies intent to abandon. Whether the applicant shall be required to put that abandonment in set words is a matter within the discretion of the office. The Examiner's action was approved. *Ex parte Witty* and *Caffrey.* Appeal from the action of the Examiner, who required an applicant to amend his drawings so as to show a modification of the invention referred to as a mechanical equivalent. BUTTERWORTH, Commissioner, held that the requirement of the Examiner came within the rule of *ex parte Howe* (25 O. G., 1,189) and it was therefore approved.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From November 25 to December 16, 1884 (inclusive).

Alarms and Signals:—*Time Detector*, A. Lasmoles, 308,416, Nov. 25. *Signaling Apparatus*, M. Toulmin, 308,533. *Call box*, C. Herrmann, 308,897, Dec. 9; W. B. Palmer, 308,922. *Low-water Detector*, J. M. Palmatier, 308,979; C. H. Wickersham, 309,425, Dec. 16.

Clocks:—C. H. Pond, 308,521, Nov. 25; same, 308,793, Dec. 2. *Synchronizing Device*, H. L. Bailey, 308,731; W. F. Weisgerber, 309,269, Dec. 16. *Apparatus for Setting Clocks Synchronously*, J. E. Smith, 309,000. Dec. 9, same, *Circuit Controller for Clocks*, 309,001.

Conductors, Insulators, Supports and Systems:—*Underground Conduit*, E. J. Houston, 308,612, Dec. 2. *Electric Light Conductor for Structures*, J. H. Vail, 308,713. *Brace for Telegraph and Telephone Lines*, A. H. Arnold, 308,818. *Insulating Compound and Application*, W. D. Grimshaw, 308,890, Dec. 9. *Wire Supporter*, O. M. Draper, 308,954; A. S. Weaver, 309,267, Dec. 16. *Accessible Underground Conduit*, W. K. Platt and G. A. Aldrich, 309,091. *Adjustable Resistance for Circuits*, F. J. Sprague, 309,167. *Method of Making Cables*, W. R. Patterson, 309,244, Dec. 16. *Ventilating Underground Test Stations*, same, 309,245. *Electric Light Conductor*, same, 309,246. *Joint for Lead Pipes*, same, 309,247. *Apparatus for Maintaining Connection with a Moving Instrument*, C. W. Williams, G. S. Barnum and E. B. Ives, 309,274. *Compound Wire*, F. Chillingworth, 309,439; W. Paul and T. J. Wood, 309,509. *Manufacture of*, I. A. Kilmer, 309,468. *Insulating Wires*, M. D. Fenner, 309,450.

Dynamo Machines and Motors:—*Motor*, G. Trouve, 308,534, Nov. 25; A. D. Blodgett and J. P. Tirrell, 308,548. *Armature Core for Dynamo*, F. K. Fitch, 308,601, Dec. 2. *Dynamo*, E. B. Cutten, 308,832. *Armature for*, B. F. Orton, 308,851.

Galvanic Batteries:—I. L. Roberts, 308,992, Dec. 9.

Ignition:—*Fire Arm*, R. S. H. Thompson, 309,262, Dec. 16.

Lamps and Appurtenances:—*Double Carbon Lamp*, J. A. Dalzell, 308,595, Dec. 2. *Electric Light Fixture*, J. H. Vail, 308,712. *Arc Lamp*, N. McCarty, 308,620; S. F. Van Choate, 309,012, Dec. 9; T. L. Kay, 309,392, Dec. 16; H. A. Gorn, 309,454.

Measurement:—*Gage*, J. and H. M. Goodman, 308,487, Nov. 25; C. D. Warner, 309,114, Dec. 9.

Miscellaneous:—*Means for Locating Mineral Veins*, A. P. Lighthill, 308,908, Dec. 9. *Movement Cure Apparatus*, M. G. Farmer, 309,036. *Educational Apparatus*, I. S. Kinch, 309,064.

Railway Appliances:—*Car Uncoupler*, J. D. Reed, 308,432, Nov. 25. *Apparatus for Controlling Railway Signals*, J. T. Hambay, 308,492. *Circuit Closer for Railway Switches*, same, 308,493. *Apparatus for Controlling Railway Appliances*, same, 308,494. *Railway Signal*, J. L. V. Tepes, 308,845, Dec. 2.

Storage Batteries:—*Making Electrodes for*, W. E. Case, 309,293, Dec. 16.

Telephone Systems and Apparatus:—*Combined Telephone and Automatic Fire Alarm System*, T. D. Lockwood, 308,566, Nov. 25. *Mechanical Telephone*, I. F. Tucker, 308,582. *Arm Rest for Telephone Users*, J. M. Fitch, 308,660, Dec. 2. *Transmitter*, W. H. Eckert, 308,956, Dec. 9; G. T. Woods, 308,817, Dec. 2. *Spring-jack Switch*, R. V. Freeman, 309,218, Dec. 16. *Telephone Apparatus*, T. J. Perrin, 309,357. *Telephone*, J. Lowth, 309,474, 309,475, 309,476.

Telegraphs:—*Polarized Relay*, W. B. Harvey, 308,610, Dec. 2. *Reed for Harmonic*, F. W. Cushing, 308,751. *Dynamo Multiplex*, S. D. Field, 308,835. *Telegraphy*, R. K. Boyle, 309,126, Dec. 9. *Winding Telegraph Paper*, H. F. Clarke, 309,332. *Printing Telegraph*, F. L. Pope and T. A. Edison, 10,542, reissue, Dec. 9.

Expired Patents:—A list of the more important electrical patents which expire during the current month is subjoined:—J. L. Arman, *Submarine Cable*, 73,847, Jan. 21. J. H. Bunnell, *Telegraph Repeater*, 73,774, Jan. 28. F. Bean, *Electric Gas-Lighting Apparatus*, 73,868, Jan. 28. S. G. Cabell, *Preventing Incrustation of Steam Boilers*, 73,872, Jan. 28.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

NEW YORK, FEBRUARY, 1885.

RUINOUS TELEGRAPHIC COMPETITION.

THE country is now passing through an era of excessive competition in various branches of industry. Within reasonable limits this heroic process of reaching a lower strata of prices might be considered a healthy indication, but pursued as it now is in many instances, to a point far below the actual cost of service or production, this course, if persevered in, means that the weakest must surrender, and that by devices familiar to the managers of great corporations, the employees must be taxed at present, and the public in the future, to pay for the follies of the management in the past. Those who have watched the coming in and going out of various electrical enterprises, are well aware that competition in this field has, in repeated instances, produced hardship and bankruptcy, leading, in some individual cases, to financial ruin, insanity and death. Even in the hey-day of apparent prosperity the managers of these various rival institutions are harassed by the continually increasing burden of their responsibilities, yet they toil on and on unremittingly, until the bubble inflated to its last extremity finally bursts, leaving behind it a trail of wreckage, which is scarcely removed from view before the vacancy caused by its disappearance is filled by a new aspirant for—what? It is barely possible that certain promoters are sometimes individually benefited. Years ago, one of the builders of the old Bankers and Brokers' line was heard to say that he had made $250,000 out of his contract, which was all the money he wanted, and he had decided to retire. A quarter of a century has elapsed and he has not since appeared in the arena, but he at least attained the unusual notoriety of having been satisfied with his accumulations, and if the world owed him a living the account has been settled.

By the business system and tariff now prevailing, the patron of a telegraph company may have a district call-box placed in his office free of charge, a book of blanks furnished, a messenger sent to his office for a telegram as required, which will be delivered to his correspondent in Chicago, a distance of 1,000 miles, for *fifteen* cents.

Contrary to the popular supposition, there are no improved methods of telegraphing in use which warrant so low a rate. To assert that the business public demands or even expects such a concession in prices is an absurdity. A really good telegraph service is certainly deserving of a fair profit; a profit which should cover the cost of substantial lines and of fairly paid, intelligent and contented employees. There is a certain class of messages which are promptly transmitted and delivered, but the general service is, as everyone knows, by no means perfect in all its branches. Within a few days we have seen the complaint that a telegram was handed in at the Broad street, Philadelphia station, for transmission to Harlem in this city, at 4.30 P. M. The sender started home by the 5 o'clock train, and reached the destination of his despatch half an hour before its arrival. While this delay may not have been caused by cheap rates, such examples, which are by no means infrequent, have led us to believe that the public has really needed a better service at the old rates, far more than it has a non-remunerative tariff, which tends to superinduce economical measures, really detrimental to what should be a business demanding the highest degree of efficiency in every department.

The words of William M. Swain, a pioneer in the telegraph business, are as true to-day as when they were spoken at a convention in 1853:

"There is too much cheapness and looseness in all departments of the telegraph service. Why don't your lines pay? Why is it that we hear of companies going into debt and pleading poverty? Why are there, on some lines, a set of boys, without a thought of responsibility resting upon them, intrusted with and undertaking to do a business of vast consequence, and often involving so fearful results to individuals? It is because you have *belittled* your business. . . . You take a message involving thousands of dollars, transmit it for *ten cents* (uttered disgustedly), and deliver it free, and think you have done a meritorious public act! And then, having no profits, you come with long faces, and want help, instead of doing business at living rates like sensible men."

ISOLATED ELECTRIC LIGHTING PLANTS.

THE London *Engineer* notes that about 1 per cent. of all the gas used in New York, or about 55 million feet annually, is used in 30 (?) of the largest theatres. This, it adds, at 8s. per M., ought to offer electricity a fine field. Although the price of gas in New York city has been reduced from $2.25 to $1.75 per 1,000 feet, the complaint is quite general that gas bills average higher than before. Whatever basis there may be for such assertions, it certainly appears as if there was an extensive field in this city for private incandescent lighting, which might be profitably developed by such companies as make a business of selling or leasing isolated plants. No building of any pretensions is now constructed which does not require the services of an engineer who has charge of the elevators and steam-heating service. No man should be employed for such work who is not competent to take charge of the necessary dynamo machines for a small electric light plant

Digitized by Google

especially in a city where a competent expert may be had at short notice in case of any unusual difficulty.

So many large office buildings are being placed in the market, that the competition for desirable tenants is likely to be quite active, and as steam heat is already provided, nothing more attractive could be added to promote the comfort of the occupants than an outfit of first-class incandescent electric lights. In many cases, no doubt, such a system might be extended to adjacent buildings on the same block not provided with the requisite steam appliances. This would so localize the service as to avoid the use of long, and consequently expensive underground conductors. Without denying the ultimate commercial practicability of a centralized system, it is obvious that, in order to supply a district radiating even half a mile in each direction, there must be a very large sum of money invested to provide conductors of the requisite capacity, while every foot used in carrying it past the property of non-consumers must bring an additional tax upon regular customers, making the total cost of the service more than it really should be. Given, a building where a steam plant already exists; or better still, where the original steam plant is planned with a view to running a local electric lighting system, it appears feasible to compete commercially with gas on any basis which the venders of that illuminant are likely to establish. Indeed, the comparative safety of the incandescent system is now so generally acknowledged, that its adoption for the lighting of theatres, hotels, asylums, and, in fact, all buildings where large numbers of people are congregated, might be a very proper provision for legislative enactment. While such action might be questionable, however, as being in the interest of certain corporations, there can be no objection whatever to a rebate by insurance companies in favor of buildings lighted in this manner, especially where fitted up in accordance with the regulations of the Board of Underwriters.

DEATH-IN-THE-AIR LEGISLATION.

The impending experimental trial of electric motors with a view to the displacement of the objectionable steam locomotives on the elevated railways has led us to the conclusion that upon the definite adoption of electricity for this purpose by the Manhattan Railway Company, a movement should be immediately made in the interests of the public toward placing these lines of transportation underground, where they ought originally to have been constructed. The conditions under which the elevated railway corporations were granted the privilege of occupying our principal thoroughfares have undergone material change. It is extremely problematical whether the nuisances which have been endured by property owners and by the public generally could have been foreseen or predicted by the most violent opponents of these schemes. To avoid the expense of purchasing or leasing adjacent property for station purposes, they have built their straggling structures—many of them painted green—at important street corners, thus depriving valuable business property of the light and air to which all persons are justly entitled under the common law.

The numerous and conclusive arguments with which we are all so familiar, against overhead electrical wires, are even more applicable to the elevated railways. As an obstacle in the way of firemen performing their hazardous duties, this formidable framework of iron stands practically immovable and indestructible. When surmounted by electrically charged rails the state of affairs will be incomparably worse. Thanks to the missionary efforts of the daily press, ably seconded by Professors Johnson, Bell, and other well-known experts, the community at large have become thoroughly awakened to the obstructive, unæsthetic and life-destroying qualities of aerial electric conductors. The general public, the firemen, and even the policemen, cannot but stand in awe of a structure, to touch or even to lean against which will, as they well understand, be followed by instantaneous death. Even in case electricity is not adopted for propelling the elevated trains, pedestrians and horses ought no longer be subjected to the danger and discomfort of an unintermittent shower of live coals, hammers, bolts, nuts, oil, and tobacco juice. Local steam transit has proved, from a financial point of view, to be a complete success. The elevated railroad corporations have been permitted to use the streets of the city for a sufficient length of time for experimental purposes, and now that they have demonstrated their earning capacity, public opinion must be manufactured of a sufficiently high potential to compel them to place their tracks underground. This has been successfully done in London, and while the cost is, without doubt, considerable, it has not prevented such railways from being operated at a profit. As in the case of the telegraph lines, various objections will be raised by monopolists and other interested parties against making the change, such, for example, as the disturbance of sewerage, gas and water systems, etc., but the resources of modern engineering will be found quite able to overcome all such objections, provided a sufficient allowance of money is appropriated for the work. We do not profess to be experts in engineering problems, but we venture to suggest that, if necessary, the sewers might be removed to the surface of the streets, as has been done with apparent success in Philadelphia, Pa., Paterson, N. J., and some other American cities. Although the original outlay consequent upon the construction of the underground railways would be large, yet when the expense of maintenance and the questionable permanency of the present structures are considered, no intelligent person can for a moment doubt that subterranean railways would in the end prove the most economical. It appears to be very doubtful whether the present railway lines will be of sufficient capacity to meet the demands of the traveling public for more than five years longer, therefore it is important that steps should be immediately taken to prevent, by appropriate legislation, the possibility of any further encroachments upon the vested rights of the people. The underground telegraph bill passed by the state legislature last year is very well so far as it goes, but is defective in one important respect, as its author inadvertently failed to include a specific clause prohibiting overhead electric conductors other than wires or cables, and as in the use of electricity for railway purposes it is the evident intention to utilize the rails, and for aught we know to the contrary, the entire structure, as a path for

Digitized by Google

the death-dealing electric current, it will be necessary to amend the act accordingly. It appears to be the general opinion that an attempt will be made by interested parties to amend the act in any event, as, according to its present provisions, the use of electrical apparatus of any kind anywhere above ground is absolutely prohibited, and since the modern fashion of placing business offices in the upper stories of high buildings has come into vogue, it is perhaps not unnatural that some opposition should be made by their occupants against the relegation of their telephones and district call-boxes to the sub-cellars. Still it is doubtful whether a comparatively slight inconvenience of this kind entailed wholly upon private parties should be permitted to stand in the way of a great public reform. It is rumored that a powerful secret movement in favor of the repeal of the present law has been organized by certain prominent capitalists who control the lightning-rod business, on the ground that even spiral twist conductors with gold-plated tops, fail to perform their functions when buried in the earth, and that this interest even hints at the possibility of retaliatory legislation, which will compel the Edison Illuminating company to dig up their conductors and place them on poles. We sincerely hope that no such foolish measures will receive countenance and support in an enlightened community like ours.

PRINTING TELEGRAPH LITIGATION.

The Gold and Stock Telegraph Company was organized in 1867 for the purpose of operating a system of printing telegraphs for reporting the quotations of the gold and stock exchanges in New York city, under patents of Edward A. Calahan. During the eighteen years which have elapsed since that date, this business has become very widely extended and correspondingly profitable. This company has from time to time acquired a large number of patents relating to their particular line of business, but the original patent of Calahan for a method and apparatus for printing the quotations in two lines on one strip of paper has always been regarded as one of the most important and valuable. No serious attempt to infringe this patent or to put into actual use an apparatus producing a similar result was made until within a few years, when a suit was brought against one Charles J. Wiley, who had constructed a number of printing instruments of this character, which resulted in favor of the complainants.

In the spring of 1883, the Gold and Stock company filed a bill in equity in the Circuit Court of the United States, asking for an injunction against the Commercial Telegram Company, an organization formed in this city for the purpose of carrying on business in competition with the Gold and Stock company, and employing a printing instrument invented by Stephen D. Field, which produced a record in two lines similar to that of the Calahan instrument. Judge Shipman handed in a decision on January 13th, 1885, denying the motion for an injunction. As this case has excited considerable interest in electrical circles, we have printed the decision in full in another column.

The Calahan patent will expire on April 21, 1885, and the decision of Judge Shipman must be regarded as a substantial victory for the Commercial Telegram Company, as the operation of their instruments cannot now be interfered with before the expiration of the patent, and of course not afterwards, whatever might be the result of an action for damages on the merits of the case. If, on the other hand, a preliminary injunction had been granted, the operations of the Commercial company would have been brought to a stand still during the remainder of the term of the patent, which would necessarily have had a most disastrous effect upon their business.

TELEPHONIC LITIGATION.

The American Bell Telephone Company has scored another legal victory, having obtained a favorable decision in their suits against the Overland Telephone Company for infringement of the Bell patents. It will be recollected that an injunction in this case was refused some time since by Judge McKennan at Philadelphia, on the ground that the issues involved were much the same as those in controversy in the New York suit of the same complainants against the People's Telephone Company The decision in that case having been given in favor of the patents, it seemed reasonably certain that a like result would follow in the case of the Overland company, and such in fact has been the result, although additional testimony was put in by the defense, tending to show that a pair of magneto telephones substantially similar to the apparatus subsequently patented by Bell had been constructed and used by Alfred G. Holcomb in New York city as early as 1863. A synopsis of the testimony of this claimant for the honor of the invention of the speaking telephone is given in another column. It is said that still another competitive telephone company either has been, or is about to be formed, based on the electro-phonetic telegraph patent of Royal E. House, well known as the inventor of the House printing telegraph. This invention was patented in 1868, and the patent is, therefore, near the expiration of its term. It is said to have recently been discovered that the apparatus covered by House's patent is capable of being used as a speaking telephone, although it is difficult to see how this, even if true, could enable the owners of the invention to maintain a successful defense against the Bell patents, for the reason that these have been construed by the courts to cover the method of operation as well as the apparatus. It is doubtful, however, if the promoters of most of these enterprises have any expectation of being able to maintain their claims before a court. Their principal object is rather to sell stock to a confiding public, but we should suppose that even this would have become a somewhat difficult matter by this time.

AN ELECTRIC LIGHT CONVENTION.

A convention of representatives of the electric lighting interests of the country is announced, to be held at the Grand Pacific Hotel, Chicago, February 25th. We fear that the importance of such a gathering has not been generally appreciated by those who should be most deeply interested in it. There is no branch of electrical industry so urgently in need of a periodical interchange of the views and experience of its workers, as that of lighting and transmission of power. Proper steps should be taken toward forming a permanent, and representative organization.

THE CONSTRUCTION OF LINES FOR ELECTRIC CIRCUITS.

BY THOMAS D. LOCKWOOD.

(Continued from page 5.)

INSULATORS AND INSULATION.

In the construction of electric lines, it is utterly impossible to bestow too much care upon the insulation of the conducting wires. To my mind, one of the most wonderful and valuable discoveries in electrical science, was that of Stephen Gray; viz.: the fact, that while some substances will readily conduct electricity, others oppose in a marked degree such conduction. It is I think this discovery more than all others that rendered electric telegraphy possible. Such substances as conduct easily, we call "*conductors*."

Substances which offer a high resistance to the passage of electricity, are called " non-conductors " or " insulators." It is absolutely impossible to insulate wires too well, when they are to be used in telegraphy. Defective insulation is a sufficient cause to mar completely the efficiency of an otherwise well built line, fitted with the most perfect instruments, and supplied with abundance of battery or machine power. No substance known is absolutely a non-conductor, and it is therefore quite impossible to provide an absolutely perfect insulation; the best we can do therefore is to limit the escape of the electricity, and prevent it from exceeding certain bounds. Constructors of electric lines are doubtless well acquainted with the reasons for interposing insulating substances between the line wire and its points of support, yet a careful observation of many lines which come under our notice, indicates too surely, that if the constructors of such lines know, they at least " don't care "; since some of the insulators employed, and some of the methods of employing them, exhibit a lofty contempt for the laws of electric conduction, and an apparently deep-rooted idea, that the sole reason for the use of insulators real or alleged, is that we may have something hard and round, with a groove in it, for the wire to be fastened to.

In the choice of a suitable insulator several points demand our consideration.

First: the material of the insulator. Second: the form of the insulator. Third: the attaching appliances, and the method of attachment.

As to the material—glass, hard rubber, and porcelain or earthenware, are now, in some form, almost exclusively used, and kiln-dried or otherwise prepared wood is employed to some extent.

To obtain a material for an insulator, which is *in every respect* the best, is almost as difficult as to obtain a voltaic cell which combines all the conditions of perfection. The desideratum, is to obtain a material which as nearly as possible offers an infinite resistance to the passage of electricity; which does not readily conduct heat; which is non-porous, and has a surface which is and will remain smooth and free from cracks. It should not deteriorate when exposed to the weather, and should be a non-absorbent of moisture. No material has as yet been found which is free from all objection. There is also one more qualification which enters in a very marked manner in the choice of material in America—that is " cost "—it must be cheap—or it will not be considered.

Glass demands the first place, since in America it is almost universally employed. It meets many of the above conditions—being of high resistance—non-porous, non-absorbent, and readily obtainable of smooth and permanent surface. On the other hand it is a fair conductor of heat, and condenses the moisture upon its surface very readily, and is moreover very brittle and thus particularly defenceless with reference to the attacks of the small boy. In the climate of England, the surface of a glass insulator is almost always covered with a film of moisture to a greater or less degree, and therefore glass is not in that country preferred. In the United States where the climate is drier, this trouble has not proved sufficiently grave, to counterbalance its many advantages, and glass is accordingly used, more than any other material.

When insulators are well made of the best glass, and are rightly shaped, they give in a reasonably dry climate very good results, and if proper methods of testing were invariably adopted, and all insulators found faulty thrown out, the average of insulation would be greatly improved.

Hard rubber is used to a considerable extent in city and short line work, and is in the form of the well-known rubber hook, well adapted for covered wire or bare wire not over No. 12 B. W. G. also for soft copper loops. It has many good features: high resistance, strength and convenience. Its defects for this purpose, are its comparatively high cost, and also the rapid deterioration of its surface, which, when exposed to the weather soon becomes rough, and spongy, after that it has a tendency to gather and accumulate dirt and moisture, and its insulating properties are a thing of the past.

Porcelain is the material chiefly employed at the present time in England and European countries. It is a good insulator, is easily moulded into the desired shape, has a good smooth surface, and properly manufactured gives satisfaction. Unless however the manufacturer can be depended on, the porcelain insulator is treacherous, holding out, if defective in mass only until the external glaze cracks. When it is good, it is very good—and will no doubt continue to be used extensively in England. It is not a cheap material and this together with the fact that glass is found to answer, have kept it from general use in America.

Earthenware has been much used but its employment is diminishing in extent—its chief advantage is cheapness. The form of the insulator is of equal importance with the material. Why? Because though an insulator when compared with the material of the line conductor, it is none the less a conductor, when considered specifically; and as a conductor it is amenable to the law of conductors; that is, the less the diameter and the greater the length of the surface, the greater is the resistance exposed to the escape of the current. This teaches that we should make the insulator of such a form, as to bring a considerable length of surface between the point where the wire is supported, and the point at which the insulator itself is affixed to the pin or bracket; while it should also be made so as to expose very little width of surface between the same points. Another point also requires some attention: in making insulators which meet the above requirements, the necessary quality of strength must not be overlooked.

The insulator shown in figure 3 below, is now much used in England and is well adapted for insulating purposes, on account of the great length of the surface between the wire and the pin.

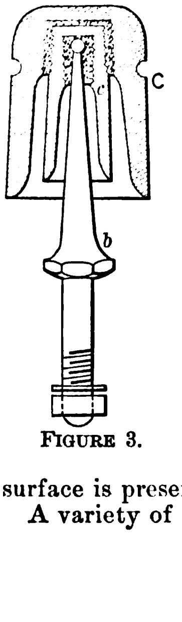

FIGURE 3.

It consists of two cups, one inside the other; the inner cup *c* is fixed to the outer cup C, by cement, and the bolt *b*, is cemented into the inner cup.

The glass insulator used in the United States is by no means so perfect as regards form. It is shown in the figure below; and has but one cup, furnished with a skirt which overhangs the surface of the pin. The length of surface is much less than the English form, and escape is proportionately easy. Could we obtain the glass insulator provided with the concentric cup, insulation would be improved.

An attempt has recently been made to improve the American insulator in this respect, by slitting the thread which screws on the pin vertically, so that less surface is presented to the pin.

A variety of porcelain knob has been used to some ex-

Digitized by Google

tent of late years as a pole insulator. It consists merely of a short porcelain knob of cylindrical form, and having a countersunk wood screw hole extending through it. It is fastened on with a single screw which passes through this hole. It is hardly worth calling an insulator, although some telephonic constructors of sanguine and imaginative temperament have used it in that capacity. Neither size nor shape is adapted for such a purpose. The knob was made to serve as an attachment, for use especially in protected places to which covered wires might be fastened. As an attachment it is all right. As an insulator it is worthless.

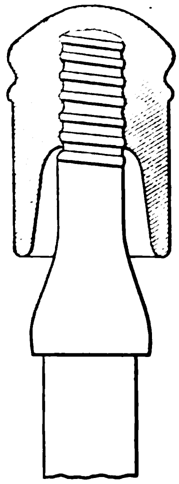

FIGURE 4.

ATTACHING APPLIANCES.

The English porcelain insulator has until quite recently been cemented, in the way shown in figure 3, to the head of an iron pin, the pin being furnished with a heavy bolt at its lower end, this being adapted to pass through the cross arm, and to be held by a nut on the lower side. Cements in insulators are always bad, and this arrangement has not been satisfactory. Recently an improvement has been introduced, substantially the same in effect with the screw attachment which we in America have so long utilized.

The way it is applied to the English insulator is clearly shown in figure 5.

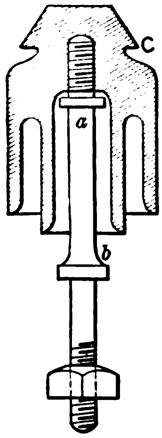

FIGURE 5.

The ordinary method of attaching the insulators in this country is indicated by figure 4, and is simply to mould a thread in the hollow or cup of the insulator, to cut a corresponding thread on the pin which is of wood, and to screw the insulator into place on the pin. A remarkable patent was taken out last spring for what was entitled "Means for Insulating and Supporting Electrical Wires." The alleged insulator comprises a block of wood, notched like a clothes pin to some depth, and having in some instances a flat surface for nailing to poles, and in others, a wedge-shaped end to drive in holes bored in cross arms. The block may be nailed through its solid part to the pole; a sheet of pliable india-rubber or some such material is doubled and placed in the slit, and the line wire is slipped up between the two surfaces of the rubber. The free or open ends of the slitted block, are then to be nailed together and to the pole, clamping the wire. This is said to give excellent insulation and to be very cheap.

We are reminded of an anecdote of the late French General Bosquet; who, it is said, after watching the British Light Brigade, 600 strong, charge the entire Russian army at the Crimea, remarked "This is magnificent, but it is not war." So with respect to this device we are constrained to say: "It may be neat, it may be cheap, it may be durable, but it is not an insulator." The American constructor will do well to stick to glass and bracket for a while longer.

Insulators should be attached where they can be well washed with every heavy rain. They should never be attached horizontally or below a cross arm because in that case the water from rain flows in, and makes a first-class conducting surface to the pole. Hook insulators especially should never be placed with the petticoat upwards. A short line does not need the extreme care in the choice of, and attachment of insulators that is essential to the good working of a long one. A single telephone line will often work clearer during the transmission of conversation when it is slightly leaky, provided the leakage is uniform; and it is indeed surprising to note, how little the telephone depends upon insulation.

As we cannot however maintain a uniform leakage—and as moreover we need a well insulated line to send call signals over, it is found more satisfactory on the whole to insulate the line well; especially when more lines than one are extended on the same poles, because in that case the leaking currents pass into other wires disturbing and confusing the passing messages. A great deal of the alleged induction between telephone wires, is without doubt due to direct leakage between wire and wire.

The excellence of the insulation of a line depends upon several conditions: The material and form of insulator, the number of supports per mile, and the size of the conducting wire, all have their share in determining this function.

According to Culley, insulation should never fall below 200,000 ohms per mile in wet weather.

(*To be continued.*)

STATISTICS OF ELECTRICAL PATENTS ISSUED FROM THE U. S. PATENT OFFICE IN 1884.

BY T. D. LOCKWOOD.

THE following statistics relative to the issue of electrical patents during the year 1884 have at least one merit. They are early—and, I think, correct. As everyone knows who has tried to classify electrical patents, the work is not easy. A patent for a cable, for example, may include a device for preventing induction—in such cases I have regarded the patent as being for the invention claimed.

The total number of patents issued for electrical inventions during 1884 is 1,166. Total number of patents issued in 1884 is 18,799.

SUBJECTS OF INVENTION.

Telegraphs.	
Autographic Telegraphs	3
Automatic "	7
Fire Alarm and District Telegraphs	30
Telegraph Instruments, Keys, Relays, Repeaters, etc.	17
Multiple Telegraphs, Duplex, Quadruplex, etc.	19
Printing Telegraphs	32
Telegraphy—New Systems	13
Alarms.	
Annunciators—Indicators and Alarms	42
Burglar Alarms, and Watch Clocks	10
Railroad Signals	46
Electric Lighting.	
Arc Lamps	82
Incandescing Lamps	40
Electric Lamp Fixtures and Fittings	2[illegible]
Electric Lighting Apparatus, Switches, Cut-outs, etc.	30
Sources of Electricity, Primary or otherwise.	
Primary Voltaic Batteries	31
Dynamos and parts thereof	75
Regulators for Dynamo Electric Machines	22
Secondary Batteries	36
Conductors.	
Cables, Compound Conductors and manufacture of the same	41
Insulated Wires, etc.	17
Insulating Materials.	
Line Wire, Compound Wires, etc.	13
Underground Systems	51
Construction.	
Couplings, Binding Screws, Joints	11
Inside Construction	1
Insulators for Pole Lines	18
Supports and Poles	14
Special Systems of Utilization.	
Clocks, Time Regulators and Distributors	30

Electro-magnets	6
Galvanometers and Measurement	5
Switch-boards and apparatus therefor	13
Telephones, and Telephonic Appliances.	
Transmitters	51
Receivers or Reproducers	26
Telephone Apparatus including automatic switches, etc, but excluding signals	40
Telephone Exchange Systems, and circuit arrangements	18
Individual Signals	6
Telephonic Repeaters or Relays	2
Telephone Signaling Appliances	22
Mechanical Telephones	14
Miscellaneous Applications	89

It is thus seen that telephonic invention still heads the list with 179 patents, electric lighting closely following with 177.

Considering the inventors from an alphabetically arranged list it is found that the number of patents assignable to each letter of the alphabet is as follows:

Inventors having the initial A — 21; B — 107; C — 57; D — 49; E — 39; F — 47; G — 60; H — 93; I — 1; J — 24; K — 32; L — 45; M — 58; N — 10; O — 10; P — 63; Q — 0; R — 44; S — 150; T — 60; U — 1; V — 60; W — 133; X — 0; Y — 1; Z — 1—total, 1,166.

The banner letter is thus found still to be S, presumably owing to the legendary impatience of our common ancestor Adam, who, it is said, after naming the greater part of his descendants became very tired, and gave utterance to the immortal dictum, "Let all the rest be named Smith."

The letter W takes the second place with 133, owing to the inventive efforts of Messrs. Weston and Waring; while B is third with 107. The letters Q X alone are unrepresented.

I, U, Y and Z, have 1 each.

In 1884, there were 53 weekly issues of patents. The average weekly issue is exactly 22 electrical patents.

THE OVERLAND TELEPHONE CASES.

On the 13th of January, 1885, Judge Butler, in the United States Circuit Court, granted to the American Bell Telephone Co. a preliminary injunction restraining the Penn Overland Co., of Pennsylvania, from using a transmitter and receiver in telephones claimed to be an infringement of the Bell patent. This motion was originally made a year ago, but owing to the fact that a similar question was involved in the People's Telephone suit then pending in New York no decision was given. Recently, however, the New York case was decided in favor of the Bell patent, and the motion for the preliminary injunction was again called up before Judges Nixon and Butler several days ago. A re-argument was had upon the ground of the introduction of new matter, but counsel were limited to a day's hearing. Judge Nixon heard the case, together with Judge Butler, because of a case existing in the New Jersey courts, and which was argued for the sake of convenience, in connection with the Pennsylvania case.

Judge Butler delivered his opinion orally, and said:

In the case argued a few days ago, involving the Bell Telephone patent, the Court is prepared to dispose of the motion for a preliminary injunction, but does not esteem it necessary to file a written opinion. When the motion was called up for argument last spring the case was fully heard and counsel were listened to at great length for some three days. Upon consideration of the evidence before us and the arguments of counsel, the Court was of the judgment that everything of essential importance was embraced in the case between this same plaintiff and the several defendants with whom he contested the validity of his patent, except the claim here set up that Drawbaugh had anticipated Bell. Inasmuch as that question was involved in a case then pending in the Circuit Court of New York, which was ready or nearly ready for final hearing, the Court esteemed it unwise to dispose of that important question of fact upon ex-parte affidavits before us. The motion was laid over, therefore, to afford the parties an opportunity of having this question (the claim on behalf of Drawbaugh) settled, in that case, where, from the character of the proof, it could be done with much greater prospect of doing justice to the parties. Had it not been for the introduction of this question into the case, the Court would have granted this motion at that time.

It was not for the Court to say whether the conclusions reached in the former cases alluded to were sound, or otherwise. Proper regard for the courtesy due from one circuit to another, as well as for the importance of harmony in the decisions of the respective circuits, required that he should treat these decisions as conclusive until reversed by the court of last resort.

Upon the case in the Circuit Court of New York being disposed of, this motion was again called up. Counsel for respondents asked to be heard on the ground that new matter had been introduced since the former argument. The Court esteemed this a reasonable request, and counsel were heard. Upon full consideration of the alleged new matter and the arguments of counsel, urged with great zeal and great ability on behalf of respondent, it is the judgment of the Court that part of the new matter was involved in the former cases, and that to the extent that it was not so involved all of it of material significance was within the convenient reach, and, it is safe to believe, within the knowledge of some, if not all, the numerous counsel employed in these cases, and it was not introduced and pressed simply because it was esteemed less available—of less importance for the purposes of defense than the matters which were introduced, pressed and passed upon.

Upon full and patient examination of everything submitted to us, we believe that the alleged new matter is but the refuse and dregs of the former cases; if I might be allowed the use of so homely an illustration, I would say, but the heel taps found in the glasses at the end of the frolic.

The motion is therefore allowed.

Judge Nixon disposed of his case at Trenton by granting a similar motion for an injunction.

The new matter introduced by the defendants consisted of a number of depositions relating to an alleged prior invention of the speaking telephone by Alfred G. Holcomb, a well-known wood engraver of New York city, and a man of considerable scientific acquirements. The deposition of Mr. Holcomb contains a story but little less incredible than that of Drawbaugh. He deposed that he made experiments in New York in 1859 with a view of shortening the alphabetical telegraphic code by the use of different tones. Having made several experiments with a stretched wire and a tuning-fork, which were thrown into vibration by an electro-magnet, he says he was led to make use of a combined permanent and electro-magnet having a steel bow armature attached to the centre of a wooden sounding board. He afterwards constructed a duplicate of this instrument and attached to both of them tin speaking-tubes with porcelain mouthpieces. He claims that in the fall of 1860 he experimented with the late Dr. Leverett Bradley, and that they first tried to get the sounds of the phonetic alphabet, but that in putting these sounds together they reproduced words. He says he afterwards made other experiments with other parties, and also with his wife and other persons in New York, Cape Island, New Jersey and Cecil County, Maryland, and that he transmitted articulate speech. This, he says, was prior to the summer of 1863. He did nothing with the instrument from that time until the summer of 1877, some time after the experiments of Bell were published. He says that although diligent in trying to obtain the assistance of capitalists he was unable to do so, otherwise he would have filed an application for a patent at that date. Mr. Holcomb however failed to produce any witnesses in support of his claims who were willing to testify that they heard articulate speech, with the exception of his former wife, whose evidence in this respect was confirmatory of his own. The story is a somewhat remarkable one, for although there seems to be very little doubt from the evidence produced that Holcomb constructed in 1860 an instrument essentially the same as the Bell telephone, and which might have been capable of use for the transmission of articulate speech, it is extremely improbable that he ever made, or even contemplated, such a use of it.

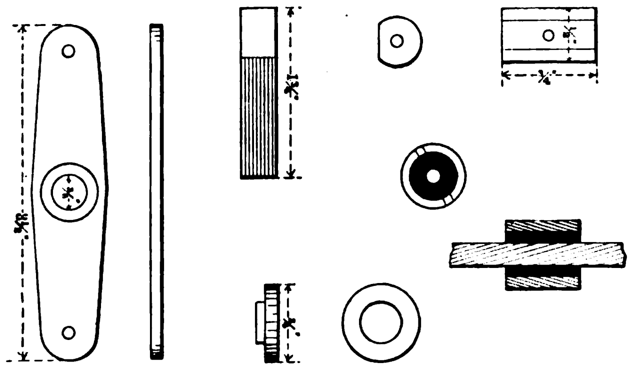
ELECTRICAL MOTORS AND THEIR CONSTRUCTION.[1]

BY JOHN E. CHASTER.

(Continued from page 6.)

THE commutator is the next portion of the motor requiring attention, and is fitted to the shaft, as shown in figure 17, partly in section, also in figure 18, by an end view. The broad, black portion represents the insulating material, such as vulcanite or hard wood, which must be bored and turned so as to fit tightly to the spindle, inside the longest bearing of the machine, as shown in figure 10. Secure it well by means of a pin driven through, or a small set screw. Next procure a piece of brass tubing that will

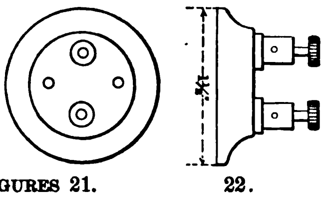
FIGURES 14. 15. 16.



FIGURES 12. 13. 19. 20. 18. 17

fit tightly over the vulcanite or wood ; this should be secured by small brass screws on the edge of the tubing, diametrically opposite. At right angles to the line of screws, with a fine saw cut the tube longitudinally, as shown in end view, figure 18. When the two segments of the commutator are removed, see that the pin or set-screw, which holds the vulcanite to the spindle, does not project so far as to touch the brasses of the commutator, when the latter is screwed home. Neither must the screws that hold the commutator be long enough to make metallic connection with the spindle. Directions will be given hereafter for making tests for faulty contacts of this nature. Figure 12 is a front, and figure 13 a side view of the holder of the commutator brushes. This fits on outside the boss of the bearing having a thread, and is held by a set-screw (see figures 19 and 20). Two small pieces of vulcanite, shaped as shown in figures 15 and 16, are screwed to either end of the commutator holder.

The commutator brushes (figure 14) are best made by cutting hard drawn copper wire into equal lengths, carefully straightening the same, and soldering them to a brass carrier. The latter has a slot cut through, so that the distance can be regulated, in order that the wearing of the commutator may be allowed for. Figures 21 and 22 are



FIGURES 21. 22.

the top and side views of a piece of polished vulcanite, with two binding screws fastened firmly to it. The ends of the binding screws must not go through to the bottom, for the reason that when the piece is screwed down to the top of the field magnets it should not make an electrical connection with the latter.

UNDERGROUND TELEGRAPHY.

THE following report upon the employment of underground lines and cables for general telegraphic purposes, which has recently been made to J. W. Mackay, President of the Postal Telegraph and Cable Co., by Sir William Thomson and Fleeming Jenkin, will be found of much scientific as well as general interest.

No. 18 FITZROY STREET, LONDON, W.

J. W. MACKAY, Esq.:

Dear Sir—In the report which we now have the honor to submit on the employment of underground wires for telegraphic communication we have made no attempt to treat the subject exhaustively. We believe that your object was to obtain our opinion on two broad questions—whether a telegraphic system could be worked rapidly and efficiently through underground lines, and whether these lines would be durable. Messrs. Siemens recommend an underground cable similar to that which is used by the German government. This cable contains 7 copper strands, each weighing 90 pounds per mile, and insulated with gutta percha weighing 76 pounds per mile. The 7 insulated wires are contained in a sheath of 24 galvanized iron wires, each 0.102 inch diameter. The weight of the iron is about 4080 pounds per mile. These iron wires are further protected by jute and compound. The weight of the whole cable is about 6100 pounds per mile. Its breaking strength is 4½ tons. This type of cable is well suited for the purpose to which it is applied.

Experience has shown that cables of this description buried in the ground without further protection are extremely durable, and are exposed to very few accidental injuries. We are unable to fix a term to the life of these cables, because up to the present time no similar cable has, we believe, required renewal or shown any sign of serious injury. These remarks apply both to the iron sheathing and the gutta percha core. No insects have, as far as we know, attacked the gutta-percha in these or similar cables, either in this country or in any other. The experience in temperate climates has been large, and some very considerable lengths have been employed by the German government to form a network of lines for military purposes. In hot countries some experience has been derived from short lengths of cable used in trenches on land to connect submarine lines with land stations. In some cases extreme heat has injured these short connecting lines, but we believe that this has occurred only where proper trenches could not be dug for their protection. We are, therefore, of opinion that, as regards durability and freedom from accidental interruption, underground cables would give very satisfactory results.

The transmission of messages through underground wires is subject to two actions which tend to limit the number of signals which can pass from station to station in a given time. The name induction is commonly applied to both these actions, which may be distinguished one from the other as static induction between the copper conductors and the earth, and magnetic induction between adjacent insulated wires. We believe that in all cases likely to arise in practice, magnetic induction may be neglected, and, moreover, its effects can in some degree be neutralized by judicious arrangements. The effects of static induction cannot be estimated by any known contrivance. The well-known limitation of speed through submarine cables is due to static induction, and a similar action takes place in all underground wires. Formulæ derived from submarine lines enable us to calculate with considerable accuracy what traffic can be passed through long underground lines of a given type when these are worked with the same expensive instruments as are employed for the submarine lines. Thus, with the type of cable described above, we reckon that by using the siphon recorder, or mirror instruments, a good clerk would work at his full speed sending from 20 to 30 words per minute through any length not exceeding 1000 miles. A high class of clerks would, however, require to be employed, and it is possible that magnetic induction from wire to wire would in these great lengths be inconvenient. We do not believe that transmission by underground lines in this manner would be likely to compete on favorable terms with transmission by overhead wires. It has therefore been our duty to satisfy ourselves as to the traffic which could be carried on by ordinary apparatus through the underground lines. The officials of the English post-office informed us that they were without any knowledge on the subject, but Mr. Preece, the engineer-in-chief, was, however, so obliging as to offer us for experiment the use of some new underground wires now being laid near London, and we made a series of experiments, with the following results, using a good Morse recorder and a Wheatstone automatic sender:

Length of Line. *Miles.*	*Words per Minute.*
27	more than 220
88	130
116	100
181	35

Digitized by Google

On the length of 181 miles a similar experiment was tried with hand sending and a Morse sounder, as the receiving instrument worked by a relay; 30 words per minute were sent, and probably the full speed of 35 words could have been reached by a good clerk. The general conclusion is that for short lengths, such as 30 miles, extremely rapid sending by automatic instruments might be employed, and duplexing, or even quadruplexing, might be employed. On lines of 100 miles automatic instruments could still be employed with advantage, but the effects of static induction would be quite sensible and would render any speed greater than 130 words per minute difficult of attainment. The ordinary hand signaling could be practiced with no sensible impediment on all lines under 200 miles in length, and at this distance relays could be worked retransmitting the messages automatically, so as to connect places distant from each other by at least 500 miles. There is no doubt whatever that any amount of traffic could be worked through a system of underground wires at the usual rates of hand sending.

The expense of establishing underground cables must always be greatly in excess of the cost of aerial lines capable of transmitting the same amount of traffic. But in cost of maintenance we believe that an underground system would compare very favorably with aerial lines. Underground wires will also be almost wholly free from interruptions due to storms or to extremes of heat and cold, whereas aerial lines, however well constructed, must always be subject to injury from wind, snow and extreme cold.

We have heard it suggested that lines composed partly of underground wires and partly of suspended wires would be more difficult to work than lines constructed wholly on the one or the other system. This is an error. It is, however, perfectly in accordance with the theory that the addition of any considerable length of aerial wire to a long underground circuit will materially reduce the speed of working. The reduction in the speed will, however, be less than if the length of line added were also composed of underground wires. Thus, in the experiments already spoken of, an addition of 50 miles of aerial line to the 181 miles of underground line reduced the speed from 35 to 28 words per minute. But if an additional length of 50 miles of underground wire had been added the speed would have fallen to 15 words.

Yours very sincerely, THOMSON & JENKIN.

THE ECONOMICS OF INCANDESCENCE LAMPS.

In a recent communication to the London *Electrical Review*, Alexander P. Trotter says:

Dr. Fleming pointed out to me, some years ago, that the value of an incandescent lamp is the product of its candle-power into its life divided by the product of its number of watts into its price. The cost per hour for power and lamp renewals is therefore

$$n\,e\,c + \frac{p}{l}$$

where e is the number of watts per candle-power, n the cost of a watt-hour, c the candle-power, p the price of the lamp, and l the life of the lamp in hours.

It is evident that the relation between the important variables, e and l, depend on the external circumstances, n and p.

We may take as extremes, ½d. and 1½d. for the cost of an electrical h. p. of 746 watts, and for the prices of lamps, 2s. 6d. to 7s. 6d. With a 20 c. p. lamp, taking 4 watts to the candle, the cost of power per hour, at ½d. per h. p., is 0.0535d.; and at a price of 2s. 6d., and a life of 1,000 hours, the renewal cost per hour is 0.03d., making a total of 0.0835. But if, other things being the same, the efficiency is raised to 2½ watts per candle, the cost of power becomes 0.0335 and this, subtracted from the total, leaves 0.05d. for lamp renewal; this is equivalent to a life of 600 hours. An exactly similar result is obtained with power at the high rate of 1½d., with a lamp at 7s. 6d.

But with power at the high rate, and with a lamp at 2s. 6d., the life comes to 333 hours; that is if a lamp with 4 watts to the candle has a life of 1,000 hours, and an increase of efficiency from 4 to 2½ watts (or 60 per cent.) be obtained, the life may be decreased from 1,000 to 333 (or 66.6 per cent.), without altering the total cost of the system. And it follows, that if the lamp still has a life of 1,000 hours, it is worth as much as 3 of the lamps of lower efficiency.

In short, if the lamp is very expensive, say 7s. 6d., and power may be had for a mere nothing, all our attention must be devoted to prolonging the life, the efficiency being nugatory; but if we could get lamps at a fair and reasonable price, say 9d., and were forced to use some extravagantly expensive source of power, such as a primary battery, we should strive to attain a high efficiency, the life being only a question of the trouble of replacing the dead lamps.

There is, however, an aspect of the question which is, in general, more interesting than the mere structural differences of the lamps, and it applies to the whole system of incandescence lighting. The efficiency of any given lamp varies as some function of the degree of incandescence or actual candle-power; the life also varies inversely as some function of the same, and it is possible that these two functions are identical. Be that as it may, the important question then arises—at what degree of incandescence (determined preferably by the spectrum) should the lamp be run in order that $n\,e\,c + \frac{p}{l}$ may be a minimum?

It is most unfortunate that we are still practically without any authentic information on these points. It is true that it is a simple matter of measurement to determine the former, but then it is only good for one class of lamp, while time only will determine the life; moreover, where is there a lamp running day after day under the same potential and under regular conditions of work?

It appears, then, that under average conditions, if we can get a lamp taking 2 watts per candle, we ought to be satisfied (relatively) with a life of 600 to 700 hours; and when the time comes and it should have come by this time, for a shilling lamp, a long life would be a question of convenience rather than economy.

With the present high prices, the value of lamps of high candle-power is most important, and appears to be strangely neglected.

A noticeable feature in the more efficient kinds of lamps is their color; the filament is lost in a blaze of white light which puts to shame the "4 watt red-hot hairpins."

CRIBBING.

The December number of the ELECTRICIAN AND ELECTRICAL ENGINEER cribs entire, except the headings, an editorial article which appeared in the September 20th issue of the *American Machinist*, entitled, "A Bogus Electric Light Company." The article related the method employed by a New York electrical expert to prick an electric lighting bubble, and save the money of a client who had been solicited to invest in the scheme. Our electrical contemporary substitutes for ours the heading, "Saved His Money," to which variation we should probably make no objection were the article itself not credited to another journal, which is said to "vouch for" the truth of the story. As we omitted to state the name of the expert in question, neither the voucher nor the vouchee, however, seems able to tell who he is. Next time we shall endeavor to be more considerate.—*American Machinist*.

We copied the article from "another journal" in which it appeared as original, and gave what we supposed to be proper credit for it in accordance with our invariable custom. How should we know that it originally appeared in a paper which we had never seen? Our esteemed mechanical contemporary appears to have a peculiar code of ethics. He finds stolen property, from which his mark has been removed, in the hands of an innocent third party. He has not a word to say against the original kleptomaniac, but is filled with unspeakable indignation at the conduct of the holder of the goods. Neighbor, that is not even law, much less common sense!

EVOLUTION OF THE ELECTRIC RAILWAY:[1]

ITS COMMERCIAL AND SCIENTIFIC ASPECT.

BY DR. WELLINGTON ADAMS.

(Continued from page 15.)

WE must consider something besides the mere propulsion of a car. Electricity possesses innumerable novel and superior qualities or features which have never heretofore been presented to the railway constructor, although fully appreciated by railway economists. It behooves us to grasp and make the most of these. To be sure, some kind of operation may be for a while attained at maximum outlay, in a primitive, impractical manner, but that which should be striven for is maximum economy as regards mechanical return, and such perfection in operation as will insure a minimum wear and tear. The application of electricity to railway propulsion means a complete revolution in railway construction and manipulation. In dealing with electricity as an agent of locomotion, it is unnecessary that we should adhere to those methods and processes which experience has demonstrated as essential to steam locomotion. On the contrary, having a totally different element to deal with, new problems are presented and new principles involved. In handling the question of steam locomotion, Stephenson, after giving preference to the principle of traction over cables, concluded that it would be decidedly best to apply the power directly to each axle, or, better still, to each wheel of every car, and operate each car separately. Finding such an arrangement impossible, however, he next decided upon making each car at least its own locomotive. But this system also proving impracticable with steam, he, as a *dernier ressort*, adopted the "train system," with its ponderous locomotive. Had Stephenson and his followers found it as practicable with steam as we now find it with electricity to apply the power direct to each wheel, the long "train system" of locomotion would never have been instituted. One of the first requirements, therefore, of an electric railway system embodying the elements of permanency and commercial success is the abolishment of the locomotive and its essential dead weight, which in turn does away with the "train system" and its numerous objectionable features. When a number of cars are coupled together their wear and tear and weight are necessarily greater. The impetus of a train being thus increased, it becomes more difficult to stop it, and the results of an accident are more disastrous both to life and property. The amount of air always carried between the cars of a train offers great resistance. All curves must be of higher degree than would otherwise be necessary, and a very much larger percentage of power is lost in making the curves than would be the case in a system applying the power to each wheel or axle. In the train system, if one car catches fire or jumps the track, others are very likely to do the same, and thus again is the company's yearly expense greatly increased. The cars being individually heavier, and the necessity of providing for the weight of the aggregate number of cars massed together in the train system, increases the cost of the road-bed and all culverts and bridges. When we dispense with the locomotive and its attendant dead weight, we abolish the cost of the power consumed in propelling the same, and we greatly lessen the principal cause of wear and tear of the road-bed, culverts, bridges, etc., and, furthermore, we render possible the use of much lighter rails, and thus again further reduce both the first cost of construction, or the capital invested, and the cost of operation. Cars which are not being continually bumped together and wrenched to pieces by a heavy train may certainly be built lighter. In the locomotive train system the weight which must be provided to supply a proper amount of adhesion between the rails and the wheels is a *dead* weight, requiring as much power for its propulsion as is required by the remainder of the train; in fact, 19 tons of dead weight must be hauled for every ton of passengers carried. Furthermore, this necessary dead weight is a fixed quantity, and does not vary with the actual paying load to be hauled. The adhesive power and its attendant dead weight to be propelled remain the same whether the accompanying cars are but one-tenth filled or fully loaded, and railway statistics show that the average number of passengers carried by each train is but 70; whereas in a system having the tractive power distributed, whether the cars be run singly or in trains, the weight which gives the adhesive power is more nearly proportionate to the load to be carried; and the weight which contributes this adhesive power is not a dead weight, but one that the operators of the road receive pay for. As each passenger enters a car, an additional weight is supplied for the exertion of just as much extra traction between the rails and the wheels as is required to propel such an increase in the load.

Here, then, we have an expenditure directly proportionate to the demand, the height of economy being thus attained. A no less important indication in railway propulsion looks to the application of the power *directly* to the point where it is to expend itself. Be this never so desirable, however, such a thing is impossible with steam, but in every way practicable with electricity—indeed, electricity seems here to have found its grandest and most important application. Again, an all-important indication for a successful electric railway may be said to lie in the fact that an electro-dynamic machine, when operating with greatest economy and safety, must, like a generator, run at a predetermined maximum speed. Hence, provision must be made for varying the speed of the car by some other means than by varying speed of the electric motor. Means must be provided for allowing the armature, or that portion of the electric motor which revolves at a high speed, to attain full headway independently before any load is placed upon it, and the latter should be applied gradually, in order to avoid jerks. In addition to the economy and safety insured by this arrangement, we, in starting, allow advantage to be taken of the impetus of the motor in overcoming the inertia of a car; and, furthermore, we do not compel the motor to do its work rapidly, since it is a *sine quâ non* of an electric motor that it shall do its work slowly. Thus will it be possible for an electric car to attain maximum speed almost at the start, whereas from an eighth to a half mile is required for a steam engine to acquire its running speed. This one point alone renders electricity, when properly applied, particularly suitable for city surface and elevated roads, where frequent stops are necessary.

It must also be possible to vary the quantity of electricity running through the car, or, rather, of varying the quantity tapped from the main supply, without introducing useless resistance. There must, furthermore, exist at the central or generating station an automatic regulator, or equivalent arrangement, which will keep the supply of electricity in the mains always proportionate to the demand, and which shall regulate the amount of fuel consumed in the steam engine so that it likewise will be proportionate to the power or electric energy absorbed throughout the system.

But little, if anything, has been done toward developing the electric railway outside of what Dr. Siemens did in 1879, namely—the simple mounting of an electro-motor upon a car and connecting this up by means of a leather or chain belt, or by a train of cogs, with the car axle. Siemens at first built an electric locomotive, but we notice he soon abandoned this principle and began mounting his machines on each car and connecting these up with the axles by means of belts. Evidently, his discerning mind soon grasped the situation, and he began applying the power in a way better calculated to develop the superior advantages of electricity.

---

1 Read by the author before the Engineer's Club, of St. Louis, April 23, 1885, and published in the *Journal of the Association of Engineering Societies.*

Digitized by Google

Edison and Field, however, have adhered to the locomotive principle and train system, as witness their exhibitions at Chicago and Louisville.

It certainly requires but little mechanical knowledge to appreciate the weak points about all these.

In the first place, either the cars must be mounted upon their axles rigidly without springs, or else the motor, which is mounted upon the car, and the axles with which the motor is geared will move differently and will not always be in line.

Second, no form of belting will do for a practical commercial railroad—that is simply out of the question, as every engineer must concede at once.

Third, gearing between parts which move differently and are constantly getting out of line is also impractical.

But little has been done toward thorough insulation for the conductors and in devising a practical moving contact.

Absolutely nothing has been suggested as a means of economic regulation, in every instance useless resistance being used, and the current wasted in useless heat.

To recapitulate:—Among the many advantages of electricity properly applied as a motor over steam for passenger transport is the circumstance that no heavy machinery or fuel has to be carried about to set the train in motion. The carriages, running singly, may be built much lighter, thus reducing the power necessary to move them; reducing the noises made in running, greatly lessening the wear and tear of both tramway and rolling stock; reducing the first cost of cars; reducing the force required to brake the cars when going at a high speed, the impetus being less; reducing the force of concussion in case of accident, and hence the dangers and destruction to life and property consequent thereon; and, finally, permitting all bridges and other superstructures to be built more cheaply, more artistically and less weighty than has heretofore been possible. Furthermore, for the same reason, and also because of the distribution of motive power attainable, greater speed may be acquired, sharper curves rounded with less than the usual wear, and steeper grades may be climbed. Experienced and trained engineers and firemen are not required to operate an electric railway. Any boy possessed of ordinary intelligence may be taught in half an hour to manage a car perfectly and cause it to perform all the work of a steam locomotive. This feature alone does away with a great source of expense now incurred by all steam railways, whether elevated or surface. The electric system also admits of the use of large, stationary, protected steam engines of the most economical type. The use of these, as against small, exposed, portable ones, reduces immeasureably the wear and tear, as well as first cost, and also the amount of fuel necessary to develop a given amount of power; and if water power be utilized—as would very frequently be possible—the cost of operating such a railway system can be reduced to a comparative minimum. Further advantages are: Ability to get up speed quickly, which is particularly desirable for street and elevated roads; absence of noise; freedom from liability to many forms of accident now unavoidable, and from the annoyance of flying sparks, cinders, smoke, gases, grease and the many other offensive and dangerous accompaniments of our steam railway system.

The time is now surely at hand for the economic and advantageous employment of electricity as a cleanly and cheap means of effecting rapid passenger transportation through densely populated cities and across the continent. Jacobi, Davenport, Davidson, Little, Pinkus and Page were in advance of the age in which they lived. No more rapid transit was demanded at that period of the world's history. The dynamo-electric machine, which we have seen has rendered feasible the electric railway, was not then in existence; hence they were obliged to apply electricity as a primary motor, an office which is filled far more economically by the steam engine, as was shown by their contemporaries in science—those versed in mathematics and thermo-dynamics. Now, however, the time is ripe for its introduction. We have reached the period of transition from the stage of practical demonstration to that of practical application. We now know how to apply electricity as a *secondary* motor; the dynamo-electric machine has been introduced as an industrial feature of our age; the project of electric railway transportation *now* has the sanction and enthusiastic support of the learned in the sciences of electricity, dynamics and mathematics; and, lastly, we live in an age which demands more rapid transit. We think fast and live fast, and this naturally begets an almost insatiable desire and necessity to travel fast. Railroad managers are expected to provide the means of gratifying this desire with safety to passengers and without detriment to their earnings, if possible; but at all hazards to put trains through according to the latest and fastest schedule. For a number of years the regular time between New York and Chicago has been 36 hours, or a speed of 25 miles an hour, including stops. This is not what might be called slow, but the impatient public is more than ever impressed with the idea that "time is money," and that something better than this should be accomplished, in view of the improvements in rails, road beds and rolling stock. Managers, in order to meet this demand, are put to a terrible strain. They must provide the ways and means, head off competition, take the responsibilities and risks of accidents, and, what is more important than all, they must make the traffic pay.

This last requisite, in the face of rival fluctuating rates, the enormous dead weight of locomotive and tender, of sleeping and drawing-room cars, and the excessive wear and tear of track, superstructure and rolling stock, from the increased weight necessary to effect such rapid transit *with the steam system*, is not an easy thing to respond to. Managers, master mechanics and car builders have for a long time regarded the rapidly increasing weight of trains as a growing evil that should be checked, to prevent expenses from swallowing up earnings in passenger traffic. Fast running under existing conditions is extremely hazardous, as well as expensive, and this simply because of the enormous weight given to railway trains. The tractive force of 20 to 60 tons exerted by the driving wheels of a locomotive on an eighth-of-an-inch of rail soon tears a tramway to pieces. These conditions are practically reversed in the writer's electric railway system. It might almost be said that here the lighter the rolling stock the greater the possibilities as to speed. Calculations based on the numerous points of advantage herein specified show that an electric railway may be operated at an average speed of 60 miles an hour for one-third the cost of operating by steam at the same speed.

If the train system must be discarded as least calculated to develop the advantageous qualities of electricity a[illegible] plied to railway propulsion, then a practical meth[illegible] applying this power upon each car must be devis[illegible] this has by many eminent engineers been found to [illegible] no easy matter, but, on the contrary, a most complex question, fraught with many difficulties. The armature of the electric motor must run at a high speed, and its power must be transmitted to the wheels of the car by a *positive* gearing. All forms of belting were at first sight seen to be entirely impracticable; while gear wheels between parts moving differently were not to be considered. Everything electrical and mechanical, including that fundamental law of mechanics which directs that power shall in every instance be applied as *directly* as possible, seemed to point toward a direct application to the wheels. But how was this to be accomplished? As we have before noted, the armature or revolving part of the electric motor must move at a very high speed, entirely too high for the speed of a car wheel. And, furthermore, it is very evident that it was impossible to construct an "armature" upon the modern dynamo principle which should also serve as a car wheel—such a dual function was out of the question. And

Digitized by Google

yet it was imperative that the principle of the motor should be that of the most efficient type of the modern dynamo.

However carefully the reader may examine into our simple solution of this question, no adequate conception can be formed of the amount of thought and work which has been bestowed upon it.

We have succeeded in applying the power directly to every wheel, to the point of traction, where the power is absorbed, the work done; and yet our wheel is neither an " armature " nor a " field " of a dynamo. It is both combined! In other words, every wheel is a dynamo in itself. Each wheel is *animated*, having power within itself. Hence every wheel becomes a veritable locomotive. Let us for a moment look into the construction of this anomaly. It is composed of two parts, one constituting the " field " of the motor, and at the same time serving as the tire-supporting portion of the wheel; while the second part represents the " armature " of the motor, and revolves within, and in an opposite direction to, the first. Hence it will be observed that the wheel is formed of two separate and distinct parts, both of which revolve, but in opposite directions. Both parts have a continuous tendency to pull toward each other, the poles of the two electro-magnetic rings, or inductors, being always kept at a minimum distance apart. The two electro-magnetic rings mutually act upon each other inductively throughout their entire length. The inner ring

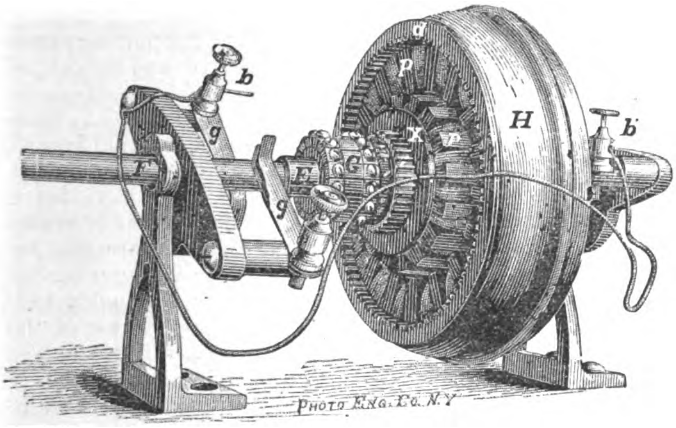

FIGURE 1.

corresponds to the armature of a dynamo machine, and revolves as 3 to 1 of the outer ring, which latter in turn corresponds to the field of a dynamo, figure 1. Their relative speeds are maintained through the agency of an epicycloidal train of either friction or toothed gearing, the internal gear being carried by the outer ring or field, while the central, or " sun-wheel," is mounted upon the hub of the armature with an intermediate friction clutch. The intermediate or floating wheel is carried by a frame, forming one with, or rigidly attached to, the car axle boxes. Thus do all geared parts move together always in line. The armature is mounted upon a hub in the form of a sleeve, which revolves upon the car axle.[2]

Here we have the weight of the machine directly at the point of traction—the tractive power is distributed to every wheel, and thus applied directly to the point of traction. The armature may revolve independently of the wheel—hence it may be allowed to attain a high velocity before applying the load, which can be applied slowly, and advantage be taken of the impetus of the armature to overcome the inertia of the car on starting. Thus also are we not obliged to jeopardize the life of the armature. Again, we are by this arrangement afforded a purely mechanical means of controlling the speed of our car without introducing useless resistance, since by allowing a slip at the friction clutch the armature will run at a proportionately higher speed and generate a higher counter E. M. F., which acts as a resistance and allows less current to pass through the machine, while at the same time the machine is working more efficiently, since its E. M. F. is approaching nearer the E. M. F. of the generator or line. In moving the field as well as the armature we produce an effect equivalent to increasing by one-third the number of sections in the armature beyond what is mechanically practical, and thus do we raise the electro-dynamic efficiency of the motor. The construction of the motor also is such as to greatly increase the leverage through which the work is done, the pull between the armature and the field being at a considerable distance from the centre. Again, the electro-magnetic construction is such that the armature and the field are subjected to each other's inductive influence throughout their entire length.

This animated wheel is particularly well adapted to one-rail elevated roads, and there is no telling what speed might be attained with wheels like this of from 4 to 6 feet in diameter. In another form I have taken the field from the wheel, and made it stationary around the axle between the wheels, the armature revolving as before on the axle, the whole forming an electric truck, see figure 2, which is in no way attached to the car, and which may therefore be removed from under or placed beneath a car at pleasure in a few minutes. Here, also, all parts are in line and move together, since the field is rigidly attached to and forms one with the car-axle box. The power is here transmitted

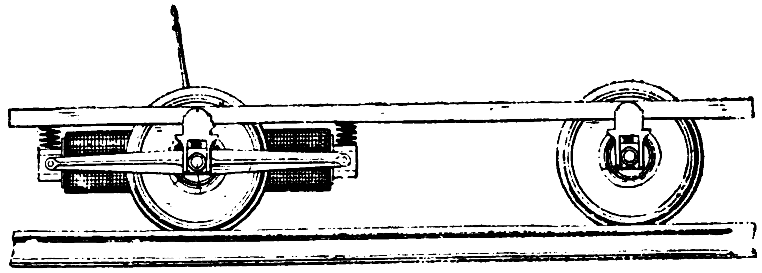

FIGURE 2.

through an epicycloidal train of friction gearing at each end of the armature.[3]

We come now to a detailed consideration of the question of percentage of return. The return of a " dynamo " machine with regard to another which puts the first in motion is expressed by the proportion of the useful mechanical work developed by the second to the work absorbed by the first. This may be estimated in two different ways: First, by applying a dynamometer to the generating machine and a Prony brake to the motor; second, by measuring the intensity or quantity of the current traversing the two machines. In the latter case the mechanical work absorbed by the first machine and that returned by the second may be ascertained by the electric measurements taken, if we but apply certain fundamental dynamic theorems. Of necessity, such a return would be somewhat higher than that obtained by direct mechanical measurements, since it is simply that which we should obtain in practice if the two machines were perfect, that is, free from friction and certain electric imperfections. Unlike the steam engine, however, which returns us but 10 per cent of our energy in the form of available work, we get in the electric engine a return of 90 per cent, the above-mentioned sources of loss consuming but 4 or 5 per cent. By Joule's law we can easily calculate the mechanical work developed in the form of heat in an INERT circuit. This is expressed by one of these three formulæ, $R\,I^2$, $\frac{E^2}{R}$ or $E\,I$.

The first supposes the resistance (R) of the circuit and

2. The lecturer here showed several models in operation.

3. The electric railway truck was here shown in operation, see figure 2.

Digitized by Google

the quantity (I) to be known; the second supposes the electromotive force or pressure (E) and the resistance (R) to be known; and the third supposes the electromotive force (E) and the quantity (I) to be known. The last two may be deduced from the first, observing Ohm's law $I = \frac{E}{R}$.

Suppose, now, that instead of the circuit being INERT it contained a perfect electric motor (of the Pacinotti type) free from friction, etc., and provided with a brake.

The total energy developed by the source of electricity now appears in the whole circuit in two different forms: heat and work. The quantity of the current being the same throughout the circuit, the heat developed in the whole circuit is expressed by $\frac{R I^2}{g}$.

The total quantity of the work generated and expended in the circuit is expressed in kilogrammetres per second by $\frac{E I}{g}$.

Supposing, now, T to be the mechanical work produced by the motor expressed in kilogrammetres per second. Then, since the total energies developed by the source equal the sum of the partial energies developed in the whole circuit, we have the equation $\frac{E I}{g} = \frac{R I^2}{g} + T$; whence it follows that we have $T = \frac{I(E - R I)}{g}$, where $E - R I$ represents a negative E. M. F. (e). Hence we conclude that where a motor performs work it necessarily generates a counter E. M. F., and this experiment proves true.

We are now, therefore, brought to the equation $T = \frac{e I}{g}$, or remembering that $I = \frac{E - e}{R}$ $T = \frac{e(E - e)}{g R}$, so that the total energy developed by the source becomes $I = \frac{E I}{g} = \frac{E(E - e)}{g R}$, and the work lost in the form of heat $\frac{R I}{g}$ or $\frac{R}{g}\left[\frac{E - e}{R}\right]^2$ or $\frac{(E - e)^2}{g R}$.

These expressions constitute the fundamental equations of the theory of the electrical transmission of power. Dynamometric measurements have of late proved that the expression $\frac{E I}{g}$ represents about .95 of the mechanical work applied to the pulley of the generator after deductions are made for the work expended in overcoming friction; that is to say, if the total work applied to the generator is represented by 100, and the work absorbed by friction by 10, the product $\frac{E I}{g}$ may reach $\frac{95}{100}$ of the remaining work ($100 - 10$) absorbed in purely electric work, or 85.5 per cent. The difference, $90 - 85.5$, then represents the loss due to electric imperfections, which I have already said amounted to 4 or 5 per cent.

These fundamental equations enable us to calculate the value of the economic return. For if we call k this return, then $k = \frac{e I}{g} \div \frac{E I}{g} = \frac{e}{E}$.

You notice, then, that this expression is *independent* of the *resistance* (R), so that we may conclude that the economic return depends only upon the proportion between the counter electromotive force of the motor and the positive electromotive force of the generator. This is what M. Deprez tersely expressed when he said, "The return is independent of the distance." The *absolute work*, however, is not independent of the distance. If we would maintain constant the work transmitted, whatever the resistance or distance, M. Deprez has shown that the electromotive force of the source must be increased proportionately to the square root of the resistance. It is a misunderstanding of this point which has led some superficial critics to dispute the results of M. Deprez's work. No rational person would advocate the possibility of transmitting the power of Niagara over a telegraph wire for an unlimited distance. Neither can I conceive of an instance where one would think of putting in a plant to transmit 10 h. p. over a telegraph wire to a point distant 25 miles from the source. Surely no one would think of establishing a plant for the hydraulic or pneumatic transmission of 10 h. p. to a point distant 25 miles. Why, then, should such absurdities be expected of electricity? In order to see the influence of resistance in the circuit on the absolute work, we must introduce into these equations the value of the return k which it is *desired* to obtain. From the equation $k = \frac{e}{E}$ we have $e = k E$, and making use of this value e in the preceding equations, they become:

Work absorbed in generator, $\frac{E^2 (1 - k)}{g R}$

Work recovered in motor, $\frac{E^2 k (1 - k)}{g R}$

Work lost in the form of heat, $\frac{E^2 (1 - k)^2}{g R}$

Thus the absolute work of the receiver may be the same in two different experiments, although the economic return

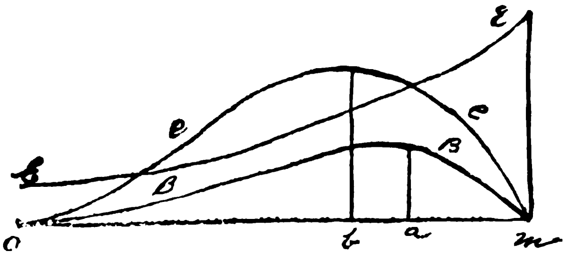

FIGURE 3.—KNAPP'S DIAGRAM FOR POWER AND EFFICIENCY.

[Speeds are plotted as abscissæ, and the electrical work absorbed in watts divided by 746 as ordinates. Then with series wound motors we obtain curve $E E$, the shape of curve depending on type of motor. Variation of speed obtained by loading brake with different weights. Maximum speed $O M$. There is a speed at which the external work is a maximum. After loading the brake with varying weights, plot resulting speeds and h. p. as abscissæ and ordinates, which produces the curve $B B$. $e = \frac{B}{E}$ made with arbitrary scale gives commercial efficiency. Speed for maximum external h. p. is $o\ a$. Speed for highest efficiency is $o\ b$.]

has very dissimilar values. These differences result from the weight put on the brake. According as the weight on the brake is great or small, so the speed of the receiver is low or high, but the work per second may be the same. This work also may be nil in two cases—when $k = 0$, and when $k = 1$.

This diagram, figure 3, very beautifully illustrates geometrically the relationship which exists between the work done and the efficiency, as also the relationship between e and E.

We see from this that there is a value for the economic return, for which the useful work of the motor is the greatest possible. The sum of the two expressions k and $1 - k$ being constant, this maximum is reached when they are equal; that is to say, when $k = \frac{1}{2}$. This further gives the

Digitized by Google

result $\frac{E^2}{g\,R}(1-2\,k)$ of the second term of the second equation. The useful work received therefore becomes $\frac{E^2}{4\,g\,R}$, and the work spent in the generator $\frac{E^2}{2\,g\,R}$. If the receiver were prevented from turning we should have $k=0$, and the work absorbed by the generator then becomes the greatest possible, or $\frac{E^2}{g\,R}$, the identical value we found for an inert circuit. From this we see that the maximum mechanical work developed by the receiver corresponds to the economical return, being equal to one-half, and that when the economic return is varied between 1 and zero the work spent in the generator constantly increases from zero to $\frac{E^2}{g\,R}$, although the electromotive force remains constant.

It is from not having well comprehended these simple considerations that many have lately written a vast amount of inaccurate criticism on the electrical transport of force. For example, one of the most common of errors is the belief that the economic return can never exceed 50 per cent, because it reaches this value when the work developed by the motor or receiver is the greatest possible in value. We have analogous conditions in thermodynamics, why not apply such reasoning in their case? Take a case in point, now, of two precisely similar machines, one acting as generator, the other as motor. Remembering that the current is equal throughout the circuit, and that a constant current produces a uniformly constant field, and that the E. M. F. of a particular generator depends upon its speed and the strength of its field, then it follows that calling the corresponding electromotive forces and speeds of the two machines e, E and v, V respectively, and k the return, we shall have $\frac{e}{E}=\frac{v}{V}=k$. We thus come back to the value $\frac{e}{E}$, which we have already obtained for the economic return by quite a different method.

Regarding the recent experiment of M. Deprez, when it is remembered that before this experiment the boldest enterprise in this direction was a 4-millemetre *copper* wire, 6,400 metres long, with a resistance of only 8.4 ohms, carefully insulated throughout its entire length, and that M. Deprez chose an iron telegraph wire exposed to the rain, 114,000 metres in length, with a resistance of 950 ohms, and that notwithstanding these enormous differences in the conditions of the two experiments, the same industrial return was obtained, namely, 50 per cent, it will be conceded that the Miesbach-Munich experiment was of the utmost importance in the history of the transport of force. In this experiment, notwithstanding the high electromotive force employed (1,400 volts) and the poor insulation of the line, not 1 per cent of the current was lost by leakage. It is extremely unfortunate for the engineering profession and the people at large that M. Deprez has been so misunderstood, for it has resulted in the creation of some very erroneous impressions in the minds of some engineers concerning the electrical transmission of power. Let me cite an instance in point: Perhaps some of you have noticed a paragraph going the rounds of your journals to this effect: "M. Deprez has succeeded in transmitting a current of electricity equivalent to 5 h. p. along a telegraph wire one-sixth of an inch in diameter, some ten miles long, with an expenditure of 29 per cent of the power. Compared with wire rope, this means falls short in actual *efficiency*" (mark you, *efficiency*), "since Messrs. Hems send 500 h. p. along a ¾-inch rope." Such logic is ridiculous, and should not find place in scientific journals. Pray tell us, in the first place, what has the *efficiency* to do with the respective sizes of the conductors in the two systems; and, second, one might as well impose upon the teledynamic advocates that they transmit their 500 h. p. by means of a ¾-inch twine, as to impose upon the advocates of electrical transmission the necessity of using an iron wire one-sixth of an inch in diameter for the transmission of the same power. As a matter of fact, we can transmit electrically 1,340 h. p. over a copper conductor of but half an inch in diameter a distance of 5 miles with a loss of but 10 per cent. in the line. Aside from the difficulties attending its subdivision and application, the transmission of such an amount of power by a wire rope of like size and over a corresponding distance would be impossible.

We come now to a practical application of these data.

Suppose we wish to determine whether it will pay to operate a street railway by electricity: Knowing the h. p. which the motor must develop in order to move each car or train over the given maximum grades at a given speed, and knowing the greatest current the conductor we provide can carry without losing more than the prescribed amount, it remains to calculate the electromotive force which the motor must develop.

Supposing the electrical efficiency of the motor to be 85 per cent, then $H=\frac{Ie}{746}\times\frac{85}{100}$; because the counter E. M. F. (e) generated by the motor multiplied by the current traversing it measures the *electrical* work it performs. Then

$$e=\frac{H\times 746}{I}\times\frac{100}{85}.$$

In order to find the E. M. F. of the generator (E):

$$\frac{E}{e}=\frac{W}{w}=\frac{Ie+I^2R}{Ie}=1+\frac{IR}{e};\quad E=e+IR.$$

Upon these and the preceding expresssions are based the following estimates as to the comparative cost of operating a street railway by horse-power, electricity, and cable:

COST OF OPERATING ELECTRIC SYSTEM.

44 cars. Speed, 6 miles. Length, $5\frac{68}{100}$ miles.

Twenty-two cars acting as locomotives, each one having an additional car attached, and being provided with 8 h. p.

Twenty-two cars, 8 h. p., multiplied by 2, on the supposition that we get but 50 per cent return, instead of 70, as is possible, = 352 = total h. p. consumed when all the cars are running and consuming full 8 h. p., a condition which never exists, even when the road is working at maximum capacity.

First item—	
Average power consumed during the running hours	200 h. p.
Pounds of coal consumed per h. p. per hour	2½
Total amount of coal consumed per hour	500 lbs.
Working hours per day	20 hours
Pounds of coal consumed per day	10,000 lbs.
Cost of coal per 1,000 lbs., $1.	
10,000 lbs. of coal at $1, $10 = cost of coal per day.	
Cost of coal per year	$3,650
One engineer at $5 per day	$5 00 per day
One assistant engineer at	2 50 per day
One electrical engineer at	5 00 per day
One assistant electrical engineer at	2 50 per day
Two stokers at $2.50	5 00 per day
Second Item—	
Total cost of labor at station per day	$20
Yearly cost of labor at station	$7,300
Third Item—	
Yearly oil and waste	$500
Fourth Item—	
One conductor to every 2 cars at	$2
One driver to every 2 cars at	2
Cost of labor on each train	$4
Number of trains	22
Total cost of labor on cars per day	$88
Total yearly cost of labor upon cars	$32,12

Digitized by Google

Three steam engines of 208 h. p. each	$7,500
Fittings for same	1,500
Two Babcock & Wilcox boilers of 460 h. p.	8,500
One Babcock & Wilcox boiler of 146 h. p. capacity	4,070
Fittings for boilers	1,000
Extras	1,000
Total net	$23,570

Four electric circuits of 2¾ miles each, having conductors with electrical capacity of 500 ampères and having a resistance of but one-fifth of the entire line, where each generator and each motor has a resistance of 10 ohms, and of which there are 11, arranged in multiple circuit, equal a copper bar of half an inch in area, costing, at 30 cents per pound:

Cost of copper conductor per mile	$2,890 60
Number of miles	11
	$31,790 00
Cost of conduit and tramway per mile of double track	$40,000 00
	2¾
	$110,000 00
Electro-motor fittings to 22 cars at $1,000 each	$22,000 00
Twenty-two electric generators at $2,000	$44,000 00
Four surplus generators	8,000 00
Total cost of generators	$52,000 00
Wear and tear on item of motors at 8 per cent	$1,320 00
Wear and tear on generators at 4 per cent	2,000 00
Wear and tear on engines and boilers	3,000 00
Wear and tear on cars, conduit and tramway	11,000 00
Total yearly wear and tear	$17,320 00
Wear and tear of conductor	Nothing
Forty-four cars	$50,000 00

Yearly Running Expenses.

Fuel	$3,650 00
Station labor	7,300 00
Waste and oil	500 00
Labor on cars	32,120 00
Wear and tear as itemized	17,320 00
Total	$60,890 00
Yearly interest on capital invested	17,361 60
Yearly expenses, including interest	78,251 60

Capital Invested.

Motors	$22,000 00
Generators	52,000 00
Engines and boilers	23,570 00
Electric conductors (copper)	31,790 00
Conduit and tramway	110,000 00
Forty-four cars	50,000 00
Total	$289,360 00
Interest at 6 per cent	17,361 60
Present yearly earnings of road upon which this estimate is based	$177,000 00
Above estimates suppose the work done to be doubled, and, consequently, the income doubled, making	$354,000 00

PRESENT COST OF OPERATION WITH HORSES.

Estimated from Data Furnished by a Railway Company—Details of Estimate.

Twenty-two cars, earning capacity	$177,000 00
Capital invested	$225,000 00
Interest at 6 per cent	13,500 00
Wear and tear at 10 per cent on invested capital, less cost of horses, the wear and tear of which is included in item of $11,710.20; allowing $25,000 to be deducted from the $225,000 as the cost of horses, leaves as invested capital to reckon 10 per cent wear and tear upon	$200,000 00
Interest at 10 per cent	20,000 00
Feed	$31,689 60
Running expenses of stables and contents	11,710 20
Stable expenses	2,185 20
Blacksmithing	2,356 20
Total	$47,941 20
One conductor on each car at $2 and 1 driver at $1.50, 22 cars, cost of labor on cars per day	$77 00
Yearly cost of labor on cars	27,874 00

Result—

Interest at 6 per cent	$13,500 00
Wear and tear on $200,000 at 10 per cent	20,000 00
Total cost of propelling power	47,941 20
Yearly cost of labor on cars	27,874 00
Total yearly running expenses	$109,315 20
Will average about	115,000 00

COST OF OPERATING CABLE SYSTEM.

The amount of coal consumed on the Clay Street Railroad is 3,600 lbs. per day of 17 hours, costing $8 per ton.

Cost of Cable Road Construction.

Will average per mile of double track	$200,000 00
Three miles	600,000 00
Two horizontal engines, 14 inches by 30 inches, set up	5,800 00
Two boilers, 52 inches by 16 feet, set up	4,500 00
Tank, pump and heater	1,500 00
Compensating arrangement at end of line	1,800 00
Driving machinery, pulley, etc	6,500 00
Twenty-two cars at $1,000	22,000 00
Twenty-two dummies fitted with grips, at $900	19,800 00
Engineering sundries, at 10 per cent, in round numbers	25,000 00
Total cost of 3 miles complete	$686,900 00
Interest at 6 per cent	41,214 00

Cost of Operation.

Maintaining cable per year		$15,000 00
Oil and waste		500 00
Maintaining conduit, tramway, and cable-bearing sheaves, 10 per cent on $600,000		60,000 00
Interest on capital invested, at 6 per cent		41,214 00
In round numbers, 600 tons of coal, at $8		4,800 00
One engineer at $5 per day, one assistant engineer at $3 per day, two stokers at $2.50 per day—labor of station per day	$13 00	
Yearly cost of labor at station		4,745 00
Cost of labor per day, 22 trains	$88 00	
Yearly cost of labor upon cars		32,120 00
Total yearly cost of operation		$158,379 00

COMPARISON OF RESULTS.

By Electricity.

Capital invested	$289,360 00
Earning capacity	354,000 00
Running expenses, including interest	78,351 00

Power consumed, and, consequently, cost of operation, more nearly proportionate to the work done, or the EARNINGS.

Great flexibility, rendering it possible to exactly adapt the capacity of the road to the varying demands.

After plant is once established, but little attention is required outside of keeping same in repair.

Amount of attention and care given to machinery manifest on the surface.

Great flexibility (that is, power to change the capacity of the road to suit varying traffic), rendering overcrowding unnecessary, and the road more *popular*, and therefore more generally patronized.

Power may be distributed throughout the district amounting to 2,000 h. p. with the same street plant and but little increase in yearly expense, bringing in an additional income of over $30,000 a year.

Engine can be reversed and cars stopped almost instantly. Curves may be made without any additional loss in transmission. Speed unlimited.

By Cable.

Capital invested	$686,900 00
Earning capacity	354,000 00
Running expenses, including interest	158,379 00

Capital confined to street railroading.

If the cable breaks the entire system is crippled, unless we use a double cable, which means still greater wear and tear and additional capital invested, upon which interest must be allowed.

Can run cars in but one direction.

Variation in speed effected at the expense of excessive wear and tear.

No engine to reverse, and, consequently, the cars cannot be stopped so suddenly.

Curves are made only with excessive loss. Speed necessarily limited. Steeper grades, however, may be ascended than would be possible under the horse-power or electric systems.

By Horses.

Capital invested	$225,000 00
Earning capacity	177,000 00
Running expenses, including interest—best year out of 10	109,315 20

Power consumed, and, consequently, the cost of operation, the same whether you carry 3,000,000 passengers or 2,000,000.

Want of flexibility as regards power to regulate the capacity of the road in accordance with the varying demands at different periods throughout the day.

More details to attend to—such as buying and disposing of horses—all of which makes more clerical work, and largely occupies manager's personal attention.

More at the mercy of unscrupulous employés, as regards the attention they give the horses.

Want of flexibility of the system renders it necessary to at times overcrowd the car, and thus is the road made unpopular.

Capital confined to street railroading.

RAILROAD TELEGRAPHS.[1]

BY CHARLES PAINE.

The telegraph has become the indispensable ally of the railroad; by its aid the capacity of a single track is doubled, and that of a double track may be very much increased; aside from its use in the movement of trains, it facilitates the rapid transaction of business to such an extent that it has become quite as important an aid to the commercial as to the operating department.

It has been sometimes attempted, even upon roads of considerable traffic, to do the business of all departments upon a single wire, no doubt from a mistaken idea of the capacity of the wire rather than from a failure to appreciate the advantages of a prompt service. It would be a grave error to allow any other business to hinder the despatching of trains, or even to interrupt it; for it will not do to confuse a telegrapher, during the transmission or receipt of train orders, by hurrying him with other matters.

It is best for a new road to build its own telegraph line, and to operate it, at first; in the rapid construction of a new road, it would be found of great advantage to erect the line as soon as possible after the location of the road had been finally determined; for the benefit derived from constant and instantaneous communication with headquarters would more than pay the extra cost of building it without the aid of railroad transportion. If the line were not too long, it could be temporarily equipped with telephones instead of telegraphic instruments, which would postpone the employment of skilled telegraphers for a while; a distance of one hundred miles or more can be talked through very satisfactorily at the present time; and with the improvements which are announced every few days, we may expect to talk well through a thousand, before long. The cost of building a telegraph line is not very considerable for a railway company, and a better bargain with any telegraph company for connections, for interchange of business, or for operating the line jointly with the railway, can be made after the telegraph line is completed than before. It should, however, be a thoroughly well built line, upon the best model up to date. The poles are larger and longer on the best lines, the wires are of greater diameter and of better material than they were a few years ago. This is the result of a long experience with lines of an inferior character; they cost more to keep in repair than good lines and were not to be relied upon. The size of the poles is perhaps the most important feature of a new line; for that limits the number of wires which can be strung upon them, and, as it is very sure that they will be loaded to their full capacity within a few years, it is best to set up those of the largest size which are now used in the best practice of the older telegraph companies. Cedar poles are regarded as best of all; white oak, chestnut and yellow pine are very good, where more conveniently obtained. The standard length of telegraph poles was formerly 24 ft.; it was found that after the part in the ground had decayed, that which had been above ground was still good. This led to the adoption of 30 ft. as the usual length, permitting the poles to be cut off at the ground when decayed, and to be reset. From 32 to 36 poles per mile is the number required. On some roads the telegraph poles serve as mile-posts, boards with the proper figures upon them being nailed to the post which is nearest to the mile-stake. By attention to this in building the telegraph line, or by resetting the poles at the mile stakes, the position of these could be cheaply perpetuated and the cost of mile-posts avoided. If, then, the intermediate posts were somewhat carefully spaced, they would be of very great convenience as reference stakes for the track department; if those at the mile stakes were to be painted white for their whole length, and those at the half and quarter miles for only a part of their length, they would afford a scale of distances which could be read in passing at the highest speeds, and be of value to the officers of the road in many ways.

The ordinary cross-arm is calculated for six wires; if it is probable that arrangements will be made with a telegraph company for connections and for the use of the railroad's right of way, it will be wise to put a second cross-arm on the poles before they are set, and to have the *gains* cut in the poles for a third cross-arm; for such work can be more easily done before the poles are set than after.

But these remarks are not applicable to an obscure branch line in an unsettled country, where possibly a single wire will serve the railway and telegraph companies both, for some years.

When possible, the poles should be set more than their length from the main track, so that if they should fall from any cause they will not obstruct it. If there are more passenger stations upon one side of the line than the other it will save crossings of the tracks, which are objectionable, if the poles are set upon the station side. In marshes it is frequently difficult to maintain a telegraph pole erect because of the softness of the ground. This can generally be accomplished by sinking a barrel without any head where the pole is to stand, then setting up the pole inside the barrel and filling between the pole and barrel with gravel or small stones.

Insulators of many varieties have been experimented with, and there are several especially fitted for peculiar situations; nothing has been found to be better for general use than the cylinder of glass screwed on to an oaken pin, a coarse thread being molded in the glass to correspond with a similar one on the pin.

No. 9 wire was formerly universally used for telegraphic purposes, now No. 6 has the preference for long lines, and No. 4 has its advocates; this refers to iron wire, of which none but the very best is fit. There are several kinds of wire of greater conductivity invented and experimented with; none established as equal to iron for main lines, as yet.

It is not intended to treat of the manifold applications of electricity to railway working; words would be wanting to represent their value and convenience; space would be lacking in which to simply mention their variety; there are excellent books on train despatching, on block-signaling, and many other special uses which should be studied by those who wish to be informed. Unfortunately, the currents from a battery are not of sufficient strength to do much work; they can sound a bell or move a hand upon a dial, conveying almost any information by concerted signals; they may be arranged to set other more powerful forces at work at any distance, and in this way render very important service in signaling. It should be oftener remembered that we have at hand this power of notifying in advance the approach of trains, whenever it can contribute to safety or convenience to do so; and at a trifling cost, even by means which are automatic, so that there is no attendant required. The incessant whistling in great yards might be totally dispensed with, and much more certain information conveyed by a line of bell signals at the switchmen's cabins. Telephones should communicate between the offices and the principal points in all important yards and termini; indeed, they can scarcely be placed upon a railway where they will not repay their cost by facilitating the transaction of business.

In the construction of its telegraph line a railroad company will need the services of experienced men, as well as in its use and maintenance afterwards. The setting of the poles, the stringing of the wires and other particulars of the work can be accomplished by experts in a fraction of the time that persons without practice would require. As in all other departments the first requisite is an energetic superintendent who thoroughly understands the details of the building and testing of a line, as well as the art of telegraphing. It will be of great advantage if he also knows something of modern progress in electrical science.

Telegraph offices should be well lighted by night, which is much neglected, as well as by day; and they should be well ventilated, because there are fumes from all varieties of moist batteries, which taint the air in addition to the ordinary causes of vitiation; they should be contrived so as to exclude the public and loafers from the apartments in which are the operators and the messages. Upon railroads, there is a disposition among all classes of employés to make the telegraph office a sort of club-room, probably because they can there learn the latest news; and on the part of the telegraphers there is a natural inclination to relieve the tedium of their office hours by social chat. It is, however, due to the accuracy and privacy of this most important mode of correspondence and of giving orders, that the telegraph office shall be entered only by the telegraphers; as little as possible even by the higher officials, who can set a good example by remaining outside, unless they must enter upon business.

ELECTRIC SIGNALING APPARATUS ON THE WEST SHORE RAILROAD.

Mr. J. E. Childs, General Superintendent of the New York, Ontario & Western Railway, has sent to Thomas W. Spencer, C. E., Inspector for the New York Railroad Commissioners, an account of the various electric and pneumatic signals applied on the 13 miles of the New York, West Shore & Buffalo Railway south of Cornwall, from which we take the following:

This portion of the track, used by the West Shore and the Ontario & Western companies, lies along the foot of Dunderberg, Storm King, Cro' Nest, and other mountainous regions of the Highlands of the Hudson, where the rocky cliffs on the one side and the very deep water on the other, necessitate considerable curvature. In some cases the water in the river was 90ft. deep, only 20 ft. from the shore, with bottom of shelving rock, where we were unable to make an embankment, and were obliged in several instances to put in long spans of iron bridges. We also have on this 13 miles two jack-knife draw-bridges, one cantilever bridge, one tunnel and the sharpest curves (though very short) upon the road. It was considered advisable on account of these features of this portion of the line, to place upon it the best system of automatic signals that could be found. Mr. George Westinghouse, of Pittsburg, having just procured letters patent upon his new automatic, electric and pneumatic block signals, we arranged with him to equip this 13 miles. The power for compressing the air is furnished by two 10 h. p. engines, located near either extremity of that portion of the line which is covered by the block signals. The air after being compressed is passed through coils of pipe and two cylinders where it is cooled, and is sent through a pipe 1 in. in diameter which is laid between the tracks. At intervals of three-fourths of a mile we have established semaphore signals for each track. These signals are located at points where they can be seen for the greatest distance, and are connected by a pipe with the main air-pipe lying between the tracks. The signals are operated by compressed air cylinders, the valves of which are controlled by electric currents, one of which passes over the line on telegraph poles and the other through the rails. The signals are controlled by short circuiting electric current in the rails when a train or engine passes over the track, the current passing through the wheels and axles from rail to rail. Opposite each semaphore signal is a battery well, built of brick below the surface of the ground, and containing for each semaphore signal a 7 jar battery. When a train passes into the block the signal immediately behind the train shows both arms at a horizontal position by day, and two red lights at night; this is called an absolute danger signal, or the second danger position. The second signal from the rear of the train shows the upper arm in an inclined and the lower arm in a horizontal position by day, and a red and white light by night; this is called the first danger position. It will be seen that by this system when one train follows within one mile and a half of another, it is warned that a train is preceding it, and the first appearance of the signal not only indicates danger but absolutely locates it. For instance, if the engineer sees a signal with the upper arm inclined and the lower arm horizontal, or showing a red and white light, he knows that a train is ahead of him, but that the block immediately ahead of this signal is clear and that the train or obstruction is upon the second block. If he sees a signal with both arms projecting in a horizontal position, or showing two red lights, he knows that the danger is imminent and that a train or obstruction of some nature is upon the block ahead of this signal. A book of instruction is furnished to employés, which, without describing the details of the signals at all, gives them all the information which they require and shows the simplicity of the system.

In addition to this, every switch upon this portion of the line is interlocked with the circuit in the track in such a manner that whenever the switch is opened two danger signals are shown upon the main track from which the switch is turned. The electric current also passes into the rails of the side-tracks out to the clearance distance, so that, should a car standing on the side-track be moved by malicious persons, or should it be blown by the wind to a point where it might interfere with the traffic, two danger signals are immediately placed automatically upon the track in the direction from which the trains approach. We also have two draw-bridges which are connected with this system in the following manner: The two jack-knife bridges on this portion of the line are connected with this system without changing the form of the automatic signals, two of them being made to act as distance and home signals for the draw-bridge. When a train approaches within 8,000 feet of the bridge, an electric bell is sounded continuously directly over the head of the watchman who attends to the draw-bridge, warning him that the train is approaching and that he must not open the draw. This bell rings from the time the train passes over a point 8,000 feet, until it passes a point 7,000 feet from the draw-bridge, when the gong ceases to sound. If, during the time the train is running from the 8,000 ft. to the 7,000 ft. point, the watchman should, contrary to instructions undertake to open the draw-bridge, he cannot do so without first setting two danger signals in the face of the train, while the train is still one and one-half miles distant from the bridge. After the train has passed over the point 7,000 feet from the draw-bridge the draw is locked by electricity and cannot be opened. As these draw-bridges are on double track the signals operate in the same manner for both directions. This I consider a very perfect system for the protection of a draw-bridge, and I could suggest only one improvement which we are now considering; that is, to have a switch near the draw-bridge, which shall throw the train off the track rather than let it into the draw in case the engineer disregards the signals. We also have some crossings protected by electric bells which ring at the crossing when a train approaches from either direction within one mile, and the bell continues to ring until the train has passed the crossing. We also have, aside from the block system, an electric tunnel block signal, protecting trains while passing through the Haverstraw Tunnel, which works automatically. When a train reaches a point within 200 feet of the tunnel, by short-circuiting an electric current in the track, a larger signal is set in the rear of the train which remains at danger and prohibits other trains from entering the tunnel until this train has passed entirely through and 200 feet beyond the tunnel, when the signal goes to safety.

During the month of October 1,065 trains passed over this portion of the line. There are in all 45 signals, including the home and distance signals for the draw-bridges,

Digitized by Google

making 47,925 signal movements during the month. From the attached report you will see that the total number of failures during this period was 68, including Oct. 28, when a break occurred in the main pipe at Fort Montgomery, which set all signals at danger—or about one-seventh of one per cent. You will observe that with only one exception the signals went to danger and consequently caused no harm other than a slight delay to traffic.

These signals have been in operation since April 1, 1884, and in that time but two failures of the signals where they were at safety and should have indicated danger have been reported. You will also observe that a number of failures occurred through broken battery jars. We found those jars were too light, and are now substituting heavier ones.

You have no doubt, seen reported in the papers that an engine ran into Popolopen draw-bridge in the month of October. This was not through any fault of the signals, as the engineer admitted, having passed the distance signal 7,000 feet and a home signal 650 feet from the draw, both set at danger. From experiments recently made, I believe that this 13 miles of automatic block signals can be operated with one engine located at a point about the centre of the system, and I shall make this change in a few weeks, which will reduce the cost of operating the signals.

THE GALVANOMETER OF D'ARSONVAL AND DEPREZ.[1]

Galvanometers of innumerable kinds abound, and each form has some special merit which renders it useful for certain restricted services. The old astatic instrument of Nobili is still preferred by many to the more modern mirror galvanometer of Sir W. Thomson because it requires no lamp, and can be used without darkening the room. The tangent galvanometer still holds its own in the testing-room for simple tests; and the lineman's detector is still indispensable on the score of its portability. For commercial purposes, where strong currents and steady potentials have to be measured, the newer ampère-meters and volt-meters have displaced the older forms of instrument. But still there is no best galvanometer of universal adaptability, even the Siemens "universal" galvanometer being too clumsy to meet with general favor.

For the purposes of the private laboratory a galvanometer is desired which shall be sensitive, yet accurate in its indications, capable of being used for measuring currents of all kinds, weak and strong, and of measuring differences of potential from the thousandth of a volt to a thousand volts. It ought to be capable of being used in broad daylight; of being rapidly read off; and it ought also to be independent of external magnetic disturbances. The annoyances which arise from the last two causes when working with sensitive galvanometers are only too well known. The needle of the instrument once deflected continues to oscillate for half a minute, perhaps longer, causing vexatious delays, and when perhaps it has settled down at last to zero, some person in the next room moves a piece of iron—a poker, a penknife, or some other magnetic object—causing the zero of the instrument to change. An aperiodic dead-beat instrument, not subject to external magnetic forces, would be a boon indeed.

A galvanometer which, without being absolutely perfect, goes very near to fulfilling these desirable conditions has lately been put into the hands of electricians by M. Carpentier, of Paris, successor to the well-known Ruhmkorff. It is the invention of M. Marcel Deprez as modified and improved by Dr. d'Arsonval. The many novel features which it presents would of themselves justify its description in the pages of *Nature*; and the general excellence of its performance, of which the writer of these lines can personally testify, is already widely acknowledged.

The main peculiarity of the new instrument lies in the fact that, whereas in almost all galvanometers there is a fixed coil and a movable magnetic needle, in this galvanometer the coil is movable and the magnet—no longer a mere needle but a substantial compound horse-shoe of steel—is fixed. Figure 1 represents the instrument itself. The steel magnet, made of three thin horse-shoes each magnetized as strongly as possible, is firmly fixed to a metal base, with its poles upwards. Between the poles hangs the coil, rectangular in form and extremely light, held in its place by a thin silver wire above and another thin silver wire below. This coil is made by winding on a rectangular core, which, after the strands have been cemented and bound together, is removed, leaving the wire only. It weighs only a few grains. To reinforce the magnetic field a small cylinder of soft iron, small enough to lie in the hollow of the suspended rectangular coil without touching it, is placed between the poles and is rigidly supported from behind. The coil is then free to turn in the very narrow space between the iron core and

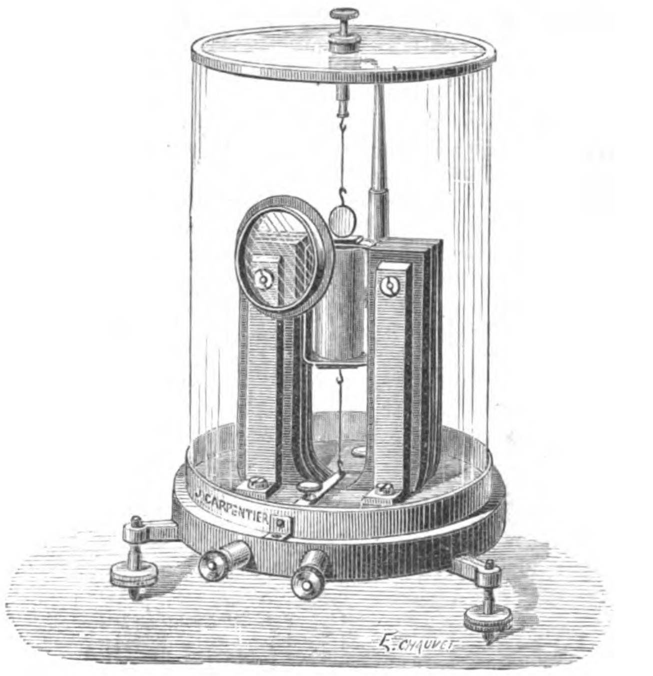

Figure 1.

the external magnet-poles; and it need hardly be added that this contrivance produces a very intense magnetic field. The current is led in by one of the silver suspension wires, and leaves the coil by the other. So far the arrangement precisely resembles that adopted in the well-known "siphon recorder" of Sir W. Thomson, invented twenty years ago for the purpose of cable-signaling. A small mirror of 1 metre focus is affixed to the suspended coil; a brass spring at the bottom keeps the suspending wires adequately stretched; and a screw-head at the top of the instrument serves both to regulate the tension in the wires and to let the coil down, to a position of rest on the central iron cylinder, whenever the galvanometer is to be dismounted for removal to a distant place. The resistance of the coil is about 150 ohms in the ordinary pattern of instrument. As there is no suspended needle, no external magnetic forces affect the zero of the instrument; and, since the position of the coil is determined solely by the elasticity of the suspending wires and the magnetic action of the fixed magnet on the current in the coil, it can be used in any position, and is independent of the earth's magnetic field. It can even be placed quite near to a dynamo machine. The intensity of the magnetic field in which the coil is situated is such that whenever the galvanometer circuit is closed—even through a consider-

1. *Nature.*

Digitized by Google

able resistance—the motion of the needle is dead-beat. It takes less than *one second* to come to rest at its final position of deflection, and when it returns to zero it does so with the most complete absence of oscillations. The spot of light on the scale never oscillates so much as 1 millimetre over the zero on releasing the galvanometer key.

The optical arrangements adopted by M. Carpentier are shown in figure. 2. The instrument is set with its three leveling screws in three V-grooves in a convenient bed-plate. Opposite it is set a semi-transparent scale of celluloid, 50 centimetres in length, graduated in millimetres. The light is provided by a single wax candle held in a holder like a carriage candle, which also carries a paraboloidal mirror back. This candle is set so that its light falls upon a small adjustable plane mirror fixed to the back of the scale. This mirror reflects the ray upon the small mirror of the galvanometer, but as it passes beneath the scale it traverses a square aperture across which a thin wire is stretched vertically. To see the spot of light the observer stations himself in front of the scale, so as to see the light coming through the strip of celluloid. He

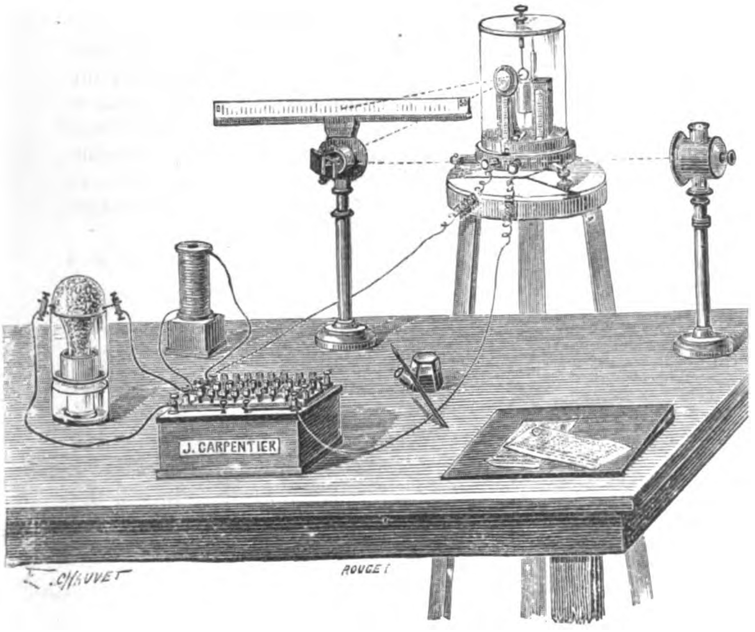

FIGURE 2.

sees a bright patch about 1 inch square having a single sharply defined black line—the image of the aforesaid wire—down its middle. This patch of light and the central line are perfectly visible in broad daylight, but cannot be well seen by more than one observer at one time. The adjustment of the lamp and scale is a simple matter; and light from any lamp in the room—an overhead gas-light for example—may be used instead by turning the adjustable mirror to the proper angle.

When set up without any shunt, this galvanometer will show a deflection of 1 millimetre on the scale for about 1.100,000,000 of an ampère of current; but the sensitiveness differs in different instruments with the construction of the coil, the stiffness of the suspension, and the power of the magnets. Two instances of its application may be given.

The instrument can be applied as a volt-meter to measure the electromotive forces of cells. An ordinary reversing key is connected to the galvanometer, and an adjustable resistance (a Wheatstone rheostat with a thin wire having a range from 1 to 200 ohms is convenient) is interposed as a shunt, across the terminals of the galvanometer. To calibrate the instrument a standard Daniell cell (E.M.F. =1.07 volt) is placed in circuit with a resistance box, the reversing key being placed between the battery and the galvanometer. A resistance of 10,000 ohms is unplugged and a reading is taken of the galvanometer, first to left, then to right, and the shunt-resistance is then adjusted until the scale reading is 53½ millimetres on either side of zero, making a total of 107 millimetres. We then know that a deflection of 1 millimetre right or left will be produced by an electromotive force of 1.200 of a volt. The cell whose electromotive force is to be tested is then substituted at B in place of the standard cell, and readings taken right and left; these are added, and divided by 100, giving the E.M.F. of the cell directly in volts.

To measure currents the same calibration is made with a standard cell. In the circuit of the current to be measured is interposed a wire of some small but accurately known resistance—for example, a standard 1 ohm, or, for stronger currents, a standard wire of 0.1 ohm. The two extremities of this coil are then connected to the key, the 10,000-ohm coil being interposed as before. If the current to be measured is 1 ampère, it will, in passing through the standard 1 ohm, produce between its ends a difference of potential of 1 volt, and this difference of potential will, when readings are taken right and left, give a total deflection of 100 millimetres to correspond to 1 ampère of current. It is not difficult to modify the arrangements so that the galvanometer may measure, on the one hand, millionths of an ampère, and thousands of ampères on the other. We have found the instrument specially valuable for indicating rapid fluctuations of current in experiments on the induction of currents in armature coils when moved in a magnetic field. Its complete aperiodicity and the very small inertia, both mechanical and electrical, of its coil, render it most valuable for such work. The only defect—and that not a serious one—observed in three months of use, is a slight sub-permanent torsion on the suspending wires after taking a large deflection; but the method of taking double readings, first to right, then to left, eliminates any error that might arise from this cause.

THE DANGERS OF INCANDESCENT ELECTRIC LIGHTING.[1]

BY C. C. HASKINS.

THE decision of the insurance companies of New York, no less than the municipal ordinances of several other cities concerning the installation of electric light wires of the several incandescent systems, requires the placing of the positive and negative wires a specified distance asunder, to the end of avoiding the possible establishment of arcs between them and the prevention of damage resulting therefrom. It is perhaps needless to say that lamps of this order are usually placed in derivation, which requires the wires to be in relatively close proximity to each other, and it is usual to place them in mouldings of wood, thus concealing the otherwise unsightly conductors. As a sequel to a friendly discussion as to the best way of disposing of such wires, relative to safety I made, in connection with Mr. Charles Wirt of the Western Edison Light Co., of Chicago, the following experiments:

1. The wire employed was No. 14 B.W.G. of copper, covered with two layers of cotton wrapping, and coated with an incombustible paint. This insulation is very good when dry, but its hygroscopic capacity renders it very susceptible to moisture, which of course much reduces its insulating properties. This wire was connected in derivation as shown.

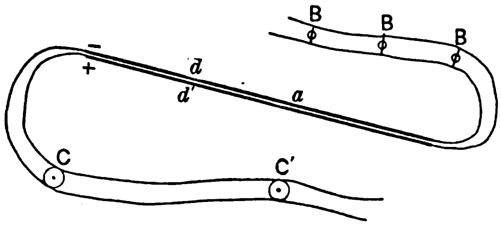
IN the figure *a* represents a wire No. 14 B.W.G; B B B are Edison incandescent lamps of 16 candle power; C C are fusible strips of the usual form. The wires were placed upon a dry pine board and bound together by means of thread, when they were liberally wetted with hydrant water. For some time no visible effect was manifested, but shortly

1. *La Lumière Electrique*, Sep. 20, 1884.

Digitized by Google

afterward a violent ebullition was observed through about an inch of contact, accompanied by very considerable heat.

Placing the dampened fingers upon the two wires quite severe shocks were experienced through their insulation, which was greatly magnified by making contact with the naked coupling of one wire, while the other hand remained upon the insulation of the other. The current with which we were experimenting had an intensity of about 0.9 ampères, the E.M.F. 110 V, and the lamps showed no per-



ceptible diminution of light. At the end of 12 minutes we opened the insulating substance on the opposite surfaces of the wires at *dd*, about 18.5 mm (.7 inches), and at the end of 5 seconds an arc was formed, and the strip C melted, extinguishing the lights.

2. Two strips of brass 125 mm (5 inches) long by 12.5 mm (0.5 inches) wide and 1.25 mm(.05 inches) thick, were substituted for the wires (these having soldered connections), firmly fixed by clamping to a dry pine board, separated laterally 77.5 mm (3.1 inches). To hasten the action of the current a solution of caustic potash was substituted for water. Ebullition was exhibited immediately, and evaporation was quite rapid. At the expiration of 8 to 9 minutes a stick of the potash was placed between the plates, but without touching either. The potash was almost immediately reduced, and the electrolytic action resulted in giving us a fine exhibit of burning potassium. Despite the drenched condition of the board it commenced to burn, and the heat developed melted the soldered connections. In 5 seconds the arc was formed and the safety strip C exploded

3. The same experiment was repeated, the action being hastened by the soaked condition of the board, the strip melting in 30 seconds.

4. Changing the plates to a dry portion of the board 6 lamps were placed in circuit at B B B, and a 9 lamp safety strip at C and C'. Two minutes only elapsed before both of these succumbed together.

5. Three lamps with a 3 light strip. Immediate melting of the strip.

6. Six lamps with a 6 lamp strip, the plates having been placed anew, and separated 37.5 mm (1.5 inches), Melting occurred in 2¼ minutes.

7. With the plates 18.5 mm (0.7 inches) apart, and 3 lights with a 3 light safety strip, the destruction of the strip was instantaneous.

8. Six lights and 6 light strip. Time 15 seconds.

9. Plates separated 10 mm (0.4 inches), 3 lamps and 3 lamp strip. Time 10 seconds.

10. Plates unchanged; 6 lamps, 6 lamp strip—5 seconds.

11. Plates 4.5 mm (0.18 inch) asunder, 3 lamps and 3 lamp strip. Time 5 seconds. In this experiment the plates were blistered by the heat.

12 and 13. Plates remaining in the same position; 6 lamps and 6 lamp strip. Fusion instantaneous.

14. Plates the same. With 6 lamps and a 9 lamp strip, 3 seconds sufficed to explode the strip.

The natural conclusion to be drawn from these results seems to me to be that the wide separating distance between + and — wires ordered by the authorities, becomes an element of danger rather than a means of protection.

It seems certain that the slower the carbonization of any combustible with which wires are in contact the more positive will be combustion when the arc is once formed, while on the contrary if the arc is formed suddenly the inflammable material will not so readily take fire, not having been exposed to the slow carbonizing process, and the danger is consequently lessened.

From this reasoning it would seem eminently safer to place properly insulated wires as near as possible to each other in installing incandescent plants.

ON A METHOD OF MEASURING SMALL RESISTANCES.[1]

BY F. UPPENBORN.

In the measurement of very small resistances other organizations must be substituted for the Wheatstone bridge, and recourse had to different methods. As the resistances to be measured become less, the resistance of the contacts introduce a constantly increasing error. Hence it becomes necessary to employ methods by which resistances of very different magnitudes may be compared independently of the resistance of the contacts.

The Wheatstone bridge is a method in which we project electrically, as it were, upon a conductor, the unknown resistance and a comparative known resistance, which conductor is by this projection divided into two parts, the respective resistances or lengths of which may be easily found. It is therefore plain that if the resistances of the contacts are great in comparison with the actual resistances, their projection if enlarged in the same proportion will sensibly affect the accuracy of the measurements. Bearing this in mind it is easy to introduce into the bridge a modification which will ensure the accuracy of the results.

This modification, generally known as Hockin's and Matthiessen's method, is represented in figure 1 :

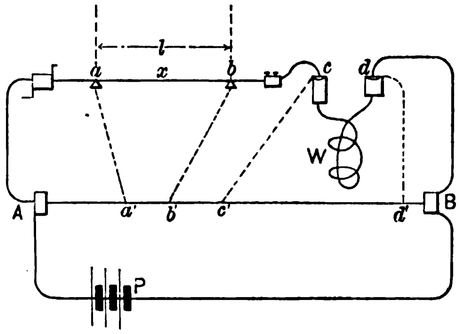


FIGURE 1.

A wire of nickel-silver, of 2 or 3mm. in diameter, and of 1 or 2m. in length, is stretched between the two clamps A and B. From these clamps proceeds a circuit containing the unknown resistance x, and a known resistance W, for which the normal unit may be chosen. To effect the electric projection in question, we establish a difference of potential between the points A and B by connecting the respective clamps with the poles of a group of elements P. We then find by trial a point in the wire A B having the same potential as the clamp or mercury cup d, to which is attached the resistance W which we assume as the standard resistance. To this end we make use of a very sensitive galvanometer, for example the aperiodic galvanometer of Thomson, Siemens, or D'Arsonval. We connect one of the terminals of the galvanometer with the mercury cup d, and the other with a contact which slides along the wire A B, and which is moved until a point, d' is found at which the galvanometer shows no deflection. The point d' is then the required projection of the point d. By the same method we project c and determine c'. If the resistance to be measured is a wire of which the specific resistance has to be found, it is well not to project the entire length of the wire upon the bridge-wire A B but to operate merely upon

1. *La Lumiere Electrique*, xiv., p. 336.

Digitized by Google

its middle portion l, the resistance of which will not be affected by the manipulations which have to be carried on to establish the communication with the terminals. By projecting the two points a b of the length l upon the bridge-wire A B we obtain the points a' and b'. The unknown resistance x of the length l is then $x = \frac{a'\,b'}{c'\,d'} W.$

This equation, however, is based on the supposition that the wire A B is homogeneous; that is to say, that any two sections of the wire of equal length offer the same resistance. To check the accuracy of this assumption we have recourse to the method of Messrs. Strouhal and Barus, which is merely the method of electric projection just explained.

For the derived circuit containing the two resistances to be compared, we substitute a series of nearly equal resistances as shown in figure 2, which are formed of 3 or 4 turns

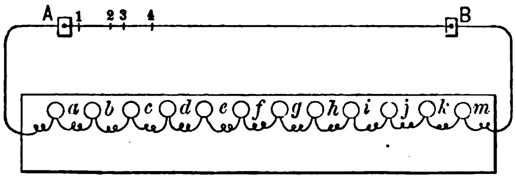

FIGURE 2.

of a wire of nickel-silver 2mm. in diameter coiled upon bobbins of dry wood. Each resistance has heavy copper terminals. The resistances are arranged upon a board, which supports a series of mercury cups. As soon as the points A and B have been connected to the battery, we project the first resistance, a b, upon the conductor A B, and obtain the points 1 and 2, which have the same potential. It is evident that this projection is wholly independent of the absolute strength of the current, which merely affects the numerical value of the potentials, not the situation of the points which we may call isopotentials.

We measure then the length of the portion 1 to 2 by a scale with the necessary precautions. We then move the resistances, a b b c, and make a new projection, which gives the length 3 to 4. We thus make a series of projections, increasing step by step the resistance, which at the outset was in front of the points a b. By this method we obtain a great number of projections of the same resistance upon different portions of the wire, A, B, which is to be calibrated. If this wire is homogeneous throughout its entire extent, the lengths as successively measured will be equal, that is to say we have 1 to 2—3 to 4—5 to 6, &c. If on the contrary, these quantities are sensibly different, it is necessary to calibrate the wire A B by means of emery paper. For this purpose we construct a table showing the several lengths projected, as well as their differences from the shortest length, which corresponds evidently to the least cross-section of the wire.

We have for example:

Place of Resistance No. 1.	Length.	Difference.
No. 1	101.3 ...	... 1.8
2	102.1 ...	... 2.6
3	103.0 ...	... 3.5
4	102.5 ...	... 3.0
5	101.2 ...	... 1.7
6	100.0 ...	... 1.3
7	100.2 ...	... 0.7
8	99.5 ...	... 0.0
9	99.7 ...	... 0.2
10	101.2 ...	... 0.7
11	100.5 ...	... 1.0
12	100.7 ...	... 1.2

We rub the wire with emery paper (excepting of course the thinnest portion, 99.5), the energy of the friction being proportional to the differences shown in the above table. When this operation is completed, we repeat the measurements already described, and so on until the calibration of the wire is perfect.

By employing a stretched wire of 1 or 2 metres we may compare resistances which have among themselves the proportion of 1-10, and that with an error less than 0.5 per cent. With a normal standard it is easy to form 10 standards, each of 0.1 ohm, which when connected in multiple arc, enable us to construct 0.001 ohm. With this latter standard we are then able to measure resistances of 0.0001 ohm, with an accuracy of 0.0000005 ohm.

We have made use of the method of Hockin and Mathiessen for determining of the conductivity of different copper wires employing a normal Siemens unit in the form of a box. In making determinations of this kind, the section of the wire of which the conductivity is to be ascertained is computed[2] from the length and weight. These two last measures, considering the perfection of the processes and apparatus now at the command of physicists, may be ascertained with great accuracy. We have thought it interesting to describe this process in a slightly modified form, which shows well the general applicability of the method.

The method of the electric projection of resistances presents incontestable advantages, and may be applied in many of the cases which electricians meet with in practice. Its only defect is the multiplicity of measurements, it being necessary to to go through four different operations with the galvanometer, in order to find the relation of the 2 resistances.

[Referring to the above article, Herbert Taylor, in a letter to the London *Electrical Review*, says that the method is of especial value in determining the temperature produced in a wire by the passage of a given current. "In the ordinary method, when the extremities of the wire experimented on are attached to massive copper terminals, at the temperature of the air, a correction for loss of heat by conduction is necessary, which correction Sir William Thomson has furnished in a note appended to a recent paper by Mr. Bottomley on this subject. This correction is somewhat complex, and may be entirely avoided by the method which Mr. Uppenborn has noticed, in which the galvanometer contacts can be shifted towards the centre of the wire."

"For the last three years I have used this method, and during that time, having taken many thousands of observations, I can speak from experience as to its utility and great convenience."

"Mr. Uppenborn refers also to a system of calibration which he attributes to Messrs. Strouhal and Barus. I do not know the date of their paper on the subject, but it was devised independently by myself in 1881, and is fully explained in a paper of that date communicated to the British Association."

"The mode proposed by Mr. Uppenborn of correcting the inequalities in the wire by the use of emery paper, is, in my opinion, very objectionable and quite unnecessary. A german-silver wire is easily procured, in which the resistance is nearly uniform, and if this is found not to be the case in a particular wire, it is better to discard it and try another sample."

"With all precautions, however, some want of absolute uniformity is sure to be found; and it is best to calibrate in the manner referred to, and prepare a table showing the necessary correction to be made on any observed reading."

"I also consider the length of wire [1-2 metres] suggested by Mr. Uppenborn insufficient to obtain the full advantage of this system of testing. The wire I employ is of platinum-iridium, 12m. long, 1.75mm. in diameter, and is wound on a drum in twenty convolutions; this wire has many advantages over German silver, being harder and not liable to injury from acid or mercury; its only drawback is its high cost, about 50s. per ounce."]

THE AMET AUTOMATIC ELECTRIC GOVERNOR.

The value of electricity as a controlling agency by which a prime motor may be promptly and efficiently regulated has long been recognized. It has been utilized for this purpose in various devices. The most successful printing telegraph instruments are driven by the accumulated power of springs, weights, or steam, the mechanism being under electrical control. Now that electric lighting has brought steam and water power into closer relations with electrical machinery, the question of instantaneous adjustment of the power to the load has become of the first importance, and this result appears to have been practically attained in the electric steam and water governor invented by Edward H. Amet. The necessity of such a governor was fully appreciated by the pioneers in the electric lighting business, and became more and more apparent as circuits were extended and it was found that lamps must be cut in and out of circuit, at a distance from the generating station.

The mechanism of this apparatus is simple, substantial and effective, and will be readily understood by referring to figure 1.

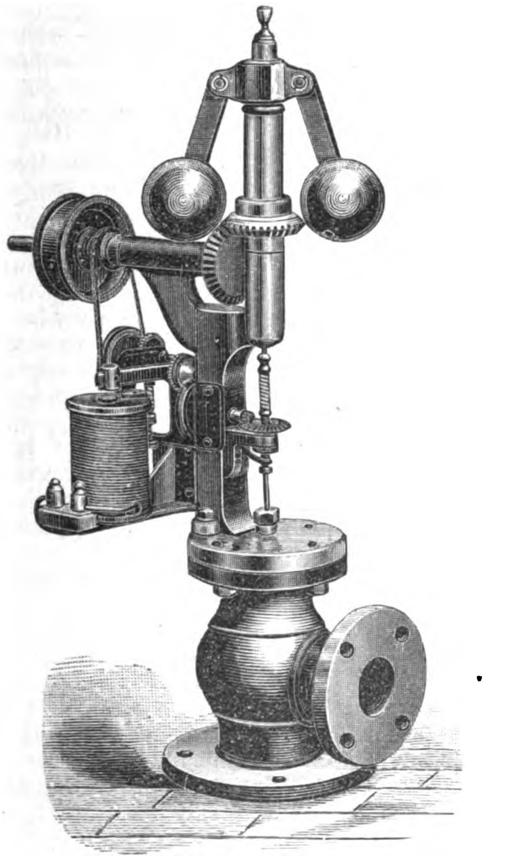

Figure 1.

A small train of gears is belted to the governor shaft, and is connected by means of friction wheels to a beveled gear, which actuates the steam valve by means of a screw thread on its stem. The contact between the friction wheels is graduated by the varying strength of the electro magnet, which is embraced in the lamp circuit. It is obvious that as the resistance of a circuit is decreased by the cutting out of lamps, the increased attraction of the magnet acting through its armature upon the friction gearing as shown, will at once shut off a sufficient quantity of steam to decrease the speed and generating capacity of the dynamo, and at once restore the normal condition of current required to operate the lamps remaining in operation.

A practical test of its efficiency was recently made at Carnegie's rolling mills in Pittsburg under rather unfavorable circumstances, but the apparatus proved equal to the task imposed upon it. The details of this trial are thus given by the *American Manufacturer:*

"The steam driving the Westinghouse engine furnishing the power for the electric lights in the above test was taken from a large pipe which was supplying one of the large engines running a train of rolls in the mill, and whenever the latter engine required an increased amount of steam the pressure was considerably reduced on the Westinghouse, thus giving the new governor a much larger range of duty to perform than is ordinarily required of any governor.

"In the test, at first 4 lights were cut out of the circuit, thus decreasing its resistance and increasing the strength of the current, which, by means of the magnet on the governor, brought into play one of the friction wheels and lengthened the valve stem on the governor, reducing the speed of the engine and dynamo to that required to furnish the number of lights in the circuit. Next, 13 more lights were cut out of the circuit, to which the governor as promptly responded, and when all the lights were thrown out of circuit the engine was just kept in motion, but ready to furnish power when required."

In adapting the governor to the control of water power a different arrangement is required, which is shown in figure 2.

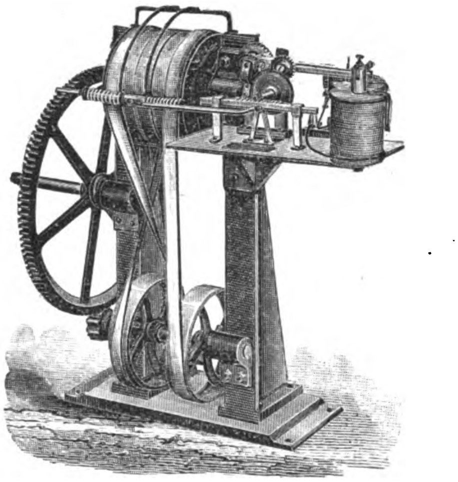

Figure 2.

In this case the gate is raised or lowered by means of the gears at the left, driven by belts leading from the pulleys attached to a running shaft which is omitted in the engraving. One of these belts is crossed, so that motion may be given in either direction. The belts are shifted from the loose to the tight pulleys or *vice versa*, by the operation of a pinion and rack, the pinion being thrown into action by the friction pulley as the electro magnet becomes vitalized, in the same manner shown in the description of the steam governor. Among the practical advantages claimed for this governor are the following: 1. It economizes power. 2. It keeps the lights at a normal brilliancy. 3. It saves the armature, and prevents fires arising from overcharged wires. 4. It maintains a uniform current. 5. It is not liable to get out of adjustment. 6. It does not burn out. 7. It will save its cost every year.

THE COMPOUND DYNAMO.

A recent number of the *Zeitschrift für Elektrotechnik*, contains an article on the use of compound dynamos for maintaining a self-regulating system of incandescent lamps. The author of the article maintains that the difference of potential at the terminals of a compound machine does not remain sufficiently constant to enable a regulator to be dispensed with. The article goes on to say that an installa-

tion of incandescent lamps cannot be considered satisfactory unless the life of the lamps averages at least 800 or 1,000 hours. To obtain this result, however, no individual lamp must be subjected to variations exceeding 1 per cent. of its normal potential. It is manifest that this degree of constancy cannot be brought about except by means of a regulator, even in the case of a compound dynamo, for if the strength of the current varies 20 per cent., the difference of potential at the poles of the machine will vary about 3 per cent. A good shunt dynamo (such, for instance, as Edison's) gives results almost as satisfactory, for an increase of 10 per cent. in the current only increases the difference of potential at the terminals by 1 per cent., while 25 per cent. increase of current only gives an increase in potential of about 4 per cent. But there are other causes of irregularity still more unfavorable to the maintenance of a constant difference of potential at the terminals. The variations in speed of the engine are seldom less than 5 per cent., and these of course cause similar variations in the difference of potential at the terminals. It is scarcely possible to install a plant so carefully that from a mechanical point of view the driver can ensure absolute uniformity in speed without a governor. The loss of potential in the conductors is another source of variation at the terminals. A plant may, in fact, be considered to be put down under exceptionally favorable conditions if the loss from this cause alone does not exceed 10 per cent.; say, 8 per cent. for the mains and 2 per cent. for the lamp branches. If then, a group of lamps be switched off, and the volume of current reduced one-half, the resistance of the main conductor is just so much reduced (?) and the lamps which remain in incandescence work under an increased potential of 4 per cent. There is a still further cause of inconstancy, viz.: the heating of the dynamos. If the internal resistance of a machine be increased in consequence of the heating of the armature wires, it necessarily modifies the difference of potential, a source of variation for which the combination of the best designed compound winding can offer no remedy. In fact, in all installations in which compound dynamos are employed it is always found necessary sooner or later to add a regulator. But if a regulator be required, as in the case of a simple dynamo, of what advantage is the compounding ? It is certain that the useful effect is not greater, for at recent exhibitions the shunt-dynamos have given the highest percentage of useful effect. On the other hand, compound dynamos have at least one incontestable disadvantage, which is, that on short circuit the conductor of the induced current is often burned in spite the best cut-outs, while with the shunt-dynamos under the same conditions only a lessening of the volume of current takes place.

With reference to the above arguments against compound dynamos, Fr. Uppenborn says that they are only apparently true. "It is neither necessary nor possible" he contends, "to attain constancy within 1 per cent. In practice, incandescent lamps constructed for a difference of potential of 100 volts exhibit a difference of 5 per cent in the potential required to raise them to the same temperature. The manufacture has not yet attained such perfection that a greater degree of precision may be relied upon. The manufacturer does not employ such accurate measuring instruments as the engineer charged with the installation, and differences of 4 or 5 per cent, are allowable. Nor is it true that a compound dynamo for an increase of 20 per cent. in current manifests a difference of potential of 3 per cent. A Schuckert machine only shows a variation of 3 per cent., in a current varying from zero to maximum. If this result cannot always be reached it is at least possible to closely approach it. The heating of the machine is not of great importance. For example a compound dynamo of which the armature offers a resistance of 0.31 ohm to 28 ampères; the resistance of copper increases 0.4 per cent. for every degree centigrade. Suppose a variation of temperature of 20° C., which corresponds with an increased resistance of 8 per cent., or 0.025 ohm. The product of the maximum current 28 ampères by 0.25 ohm, gives 0.7 volt. The field magnets are also constructed of low resistance so that the tendency to heat is inconsiderable. A shunt dynamo, other things being equal, is less constant than a compound ; and the statement that the difference of potential at the terminals of an Edison dynamo is only 1 per cent. for 50 per cent increase in current must be taken *cum grano salis*. But assuming this to be strictly true, it only proves that the dimensions of an Edison machine are quite abnormal. The field magnets are excessively large in proportion to the armatures, especially in the original American type. The machines which gave the diagrams referred to are, on the other hand, of nearly the same dimensions, and it is rational to compare them. Now, in this case, the maximum product of the current into the difference of potential at the terminals is obtained, when R=26 ohms, and from 30 to 40 ohms the difference increases about 25 per cent. This shows conclusively that it is more advantageous to construct a compound dynamo with an equal quantity of copper, because however unfavorable the conditions under which such a machine may be installed, it will never show a difference of 20 per cent."

In a recently published letter to the London *Electrician*, Mr. W. Macgregor controverts a statement which recently appeared in that journal to the effect that the first dynamo machines made practically self-regulating by the compound principle, were made and set at work by Messrs. Crompton for Mr. Coope at Berechurch Hall, near Colchester, in the spring of 1882, and asserts that the first dynamo applied practically to work on the compound-wound principle was by Dr. Paget Higgs, at Greenpoint, Long Island, in 1881. This application was made to a Wood dynamo constructed by the Fuller company, and was carried out under the instructions of Dr. Higgs himself, the series coils on one side of the machine being replaced by fine wire shunt coils. It was subsequently removed to Philadelphia, and was there publicly exhibited. The machine was driven by a Colt's 6 h. p. disc engine, running at 900 revolutions, steam being supplied by a 10 h. p. Baxter boiler. Maxim's incandescent lamps were used. Moreover, the machine had been previously seen by Professor Trowbridge, of Harvard College, to whom the compound principle of winding was explained by Dr. Higgs.

Four Gramme machines were compound-wound under Dr. Higgs's instructions as early as April, 1881, at New York, which are still at work. In November, 1881, Dr. Higgs shipped to Liverpool two compound machines wholly made by him, and one of which is still in good working order. In fact, as early as May, 1880, according to Mr. Macgregor, Dr. Higgs was constructing self-regulating machines of an experimental character in Boston, and his first application for letters patent was dated April 22, 1880. He obtained a patent on June 7, 1881, No. 242,644.

The original and first inventor of what is now known as the compound-wound dynamo, appears to have been Charles F. Brush, who fully described and claimed it in an application for U. S. letters patent filed March 11, 1878, and issued July 22, 1879, No. 217,677.

The application of it to the purpose of regulating an electric light system is not, however, suggested in this patent. It would seem that Dr. Higgs was the first to practically apply the compound-winding to this particular purpose. Edison patented on September 19, 1882, two or three plans of incandescent lighting in which the general principle is indicated, though it does not appear that he had ever practically applied it. His plans, moreover, are materially different in detail from the actual one now used, the origin of which has been the source of so much discussion in the technical journals. The series of patents, thirty-one in number, issued to Mr. Edison on the above date, contain many interesting features.

DOLBEAR'S TELEPHONIC RESEARCHES.[1]

BY PROFESSOR EDWIN J. HOUSTON.

As we have already intimated, Professor A. E. Dolbear, besides inventing the new system of electro-static telephony, has done much to give the present system of magneto-electric telephony its present commercial efficiency. His inventions in this direction cover a wide and varied field of research. We will describe some of the more interesting and valuable of these inventions.

It would appear that Dolbear was the inventor of the magneto-electric telephone. He was the first to point out the fact that the ordinary electro-magnets employed in the articulating telephone could be dispensed with, and permanent magnets used in their stead. He invented the magneto-electric telephone in September, 1876, and constructed his first magneto-electric telephone as early as October of the same year.

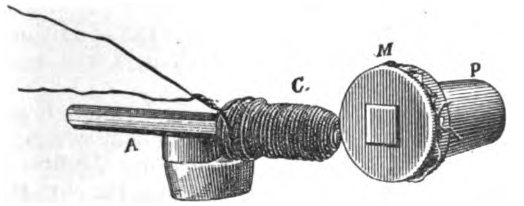

FIGURE 1.—Dolbear's Original Magneto-Electric Telephone.

In figure 1 is shown the original Dolbear magneto-electric telephone from a photograph of the identical apparatus. As will be seen, it was somewhat crude in construction but was fairly efficient in operation and contained all the essentials of the magneto-electric instrument.

A permanent bar magnet, A, had a coil of insulated wire C, wound around one end only. Its armature was formed of a rectangular piece of sheet iron fastened to the middle of a thin rubber diaphragm, that was firmly stretched on the end of one of the hard rubber tubes of an old opera glass. This form of apparatus was designed for use both as a transmitter and as a receiver, and was employed without a voltaic battery.

Crude as this instrument was, its invention marked a great advance in the art of telephony. Like many things that appear of the greatest simplicity when once originated, its successful operation could hardly have been confidently predicted. Indeed, we doubt whether most electricians would have believed that the magneto-electric currents thus generated by the voice would possess the requisite strength to reproduce the voice. It would scarcely have been considered probable that the resulting magnetic variations in the receiving instrument could produce such movements in the diaphragm as would permit it to reproduce audible, articulate speech. The scientific world was then, to a great extent, ignorant of the exceedingly small amount of motion

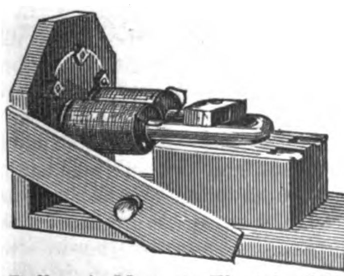

FIGURE 2.—Dolbear's Magneto-Electric Telephone (Bi-polar).

requisite to produce audible sounds. It also lost sight of the very evident fact, that the comparatively great velocity of movement of the magnetic diaphragm, must necessarily result in the production of a proportionately large current in the coils of wire on the magnet pole.

Dolbear improved the magneto-electric telephone shown in figure 1, by an instrument that he constructed in December, 1876. This form of instrument is shown in figure 2, and consists of a horseshoe magnet of round steel, that is, of course, permanently magnetized. Bobbins of insulated wire are placed on the ends of the poles in the position shown. Figure 2 is reproduced from a photograph of the instrument as actually made by Prof. Dolbear. It is interesting as showing a metallic diaphragm, bolted at its edges to the upright, wooden mouth-piece. The bobbins on this instrument were taken from an old telegraphic instrument. Dolbear employed his first metallic diaphragm in October, 1876, in an instrument used in connection with the apparatus shown in figure 1. His first metallic diaphragm consisted of a piece of sheet iron that entirely covered the end of a wooden tube.

In figure 3 is shown an ingenious form of transmitter invented by Dolbear in 1878, and named by him the finger transmitter. It consists of an empty tomato-can, the metallic bottom of which is brought into good electrical contact with one end of an electric circuit by wrapping the wire around the bottom edge and soldering it thereto. If now the wire from the other terminal of the battery circuit be grasped in the hand, and the finger be held against the middle of the bottom of the can, as shown, any sound made into the open end of the can will vibrate its bottom and thus vary the strength of the battery circuit, by reason of the varying contact of the finger and the bottom of the can. If, therefore, any form of receiving instrument be introduced into the circuit, anything spoken into the open end will be distinctly heard in the receiving instrument.

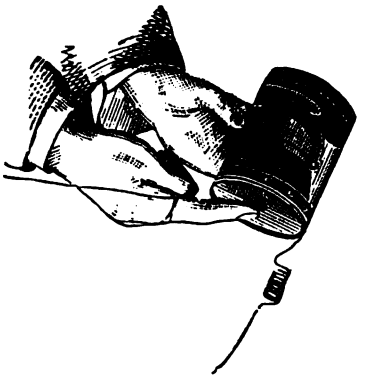

FIGURE 3.—Dolbear's Finger Transmitter.

Since the resistance of the finger is high, it is necessary to employ from 10 to 20 gravity cells in order to obtain satisfactory results.

This form of transmitter is dependent for its operation on the principle of the microphone transmitter, or in other words, it is a variable resistance transmitter. Though of comparatively little practical importance, it is interesting as illustrating the ease with which efficient telephone transmitters may be constructed; or how readily one could be devised for use in case of a sudden emergency.

In a previous article we spoke of Dolbear employing for a transmitting instrument a modified form of Reis transmitter. In figure 4, is shown a back view of one of these modified transmitters. A brass tongue, the end of which is tipped with a platinum wire is fastened to the inside of a wooden ring, so that the end of the platinum tip touches the middle of a vibrating diaphragm. The screw that may be seen passing through the cross bar, serves to regulate the pressure of the platinum tip upon the plate. The brass tongue has one of the terminals of a battery connected with it, and the metallic plate or diaphragm is connected with the other terminal. These wires are shown in the figure as passing through the handle.

Digitized by Google

This transmitter, which, it will be observed, differs from the forms employed by Reis, mainly in the fact that the ordinary membraneous diaphragm is replaced by a metallic diaphragm, has been successfully employed by Prof. Dolbear to transmit intelligible, articulate speech between Boston and New York. When used for this purpose it was included in the circuit of 100 gravity battery cells, and the speech reproduced by the receiving instrument was

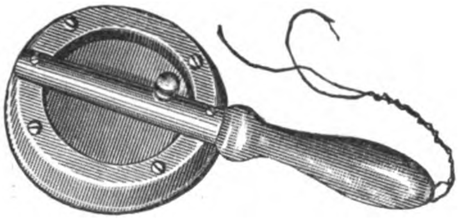

Figure 4.—Dolbear's Modified Reis Transmitter.

so loud and distinct, that it was heard at a distance of 10 feet from the receiver.

This transmitter is especially effective when included in the primary circuit of an induction coil. Without stopping here to discuss the peculiar advantages of the induction coil in telephony, it may be well to remark that the currents sent over the main line from the secondary coil are of the alternating character that characterize the magneto-electric currents.

Besides the modified Reis transmitter shown in connection with figure 4, Prof. Dolbear has invented a number of multiple transmitters ; one of these is shown in figure 5.

In this form of transmitter 4 separate terminals are shown, so arranged that all of them may be placed in the same circuit, or each may have a separate circuit of its own, and thus be employed with 1 induction coil, like a single terminal one, "or with multiple points, each with its own circuit in an induction coil with multiple primaries, or with separate coils, or any combinations of these." In this form of transmitting instrument, Dolbear has arranged the vibrating plate horizontally as in Reis's second form of transmitter.

Dolbear has invented a quite distinct genus of telephone receivers to which he has given the general name of rotophones. This instrument, like Edison's motograph, operates by variations in friction. It is quite distinct, however, in the method of its operation, an electric current being caused to modify the magnetic friction of a body attached to the centre of an elastic diaphragm.

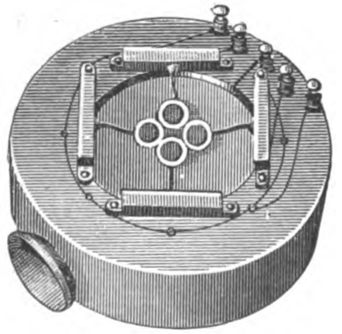

Figure 5.—Dolbear's Multiple Transmitter.

In Edison's motograph, a diaphragm is set into vibration by the variations in the friction of a metal strip on a cylinder of chalk. The chalk cylinder is saturated with an electrolyzable substance and is rotated. The passage of an electric current between the metal and the chalk will cause the friction between these 2 surfaces to become less. If, therefore, the cylinder be rotated the friction will vary with variations in the current, and corresponding movements will be produced in a diaphragm that is connected with the metallic strip.

Now Prof. Dolbear employing these variations in magnetic friction has constructed a distinct genus of re-

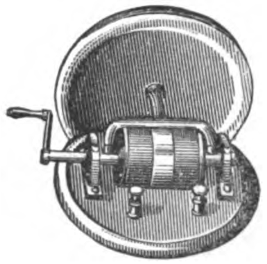

Figure 6.—Dolbear's Rotophone.

ceiving telephone, the principles of operation of which will be understood by reference to figure 6. An electro-magnet, with a straight core, is provided with a handle so that the core can be readily rotated. A flat **U**-shaped armature is provided, the ends of which are permitted to rest on the ends of the core that project beyond the coil. In the middle of the **U**-shaped armature a short rod is secured at one end, the other end of which is attached to the centre of a vibrating plate of mica, or elastic metal. The explanation of its action is thus stated by Prof. Dolbear in a paper descriptive of the rotophone, that he read before the American Academy, on May 14, 1879. "When a current of electricity is made to traverse the coil, the core becomes a magnet and the armature is attracted to it ; if the core be rotated, the adhesion of the armature will carry the middle of the diaphragm towards the magnet, and if the current be stopped, the elasticity of the plate will cause it to return to its original place. A vibrating current will thus set up corresponding vibrations in the diaphragm so long as the magnet turns."

Prof. Dolbear has produced some very simple and curious modifications of this form of telephone receiver. For example, if the end of the string of a common string telephone be tied to a nail, and the latter be placed on the pole of an electro-magnet that is in the circuit of a transmitting instrument, a person listening at the tube of the string telephone, will distinctly hear whatever is uttered into the transmitter, provided the nail is slowly drawn over the magnet pole. A motion of but two inches a minute will be sufficient in most cases.

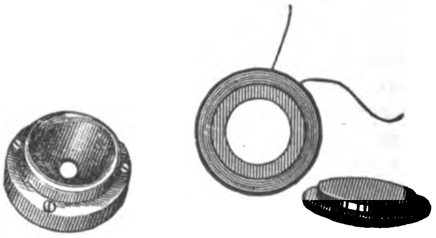

Figure 7.—Early Forms of Dolbear's Static Telephones.

In figure 7, 2 of the early forms of Dolbear's static telephones are shown. One of these consists of 2 tin discs about 2 inches in diameter, separated from each other by a rubber ring about a quarter of an inch in breadth, thus forming a true air condenser. These were mounted in wooden cases, with an opening through the face for listening.

The form of static telephone shown in figure 7, to the right, consists of a circular plate of tin securely fastened to the bottom of a shallow box. Electric conduction, between the back and front disc is prevented by the use of a ring of paraffined paper. The front disc was formed of a disc of gilt paper, tightly stretched over a ring and connected to one of the terminals of an induction coil.

Digitized by Google

The 2 forms above described in connection with figure 7, were but a few of the numerous evident modifications of the same that were tried. Dolbear also made a telephone receiver, of a series of condensing discs. In one instance as many as 50 of these separate discs were used. As might have been expected, however, this modification was not productive of any good results.

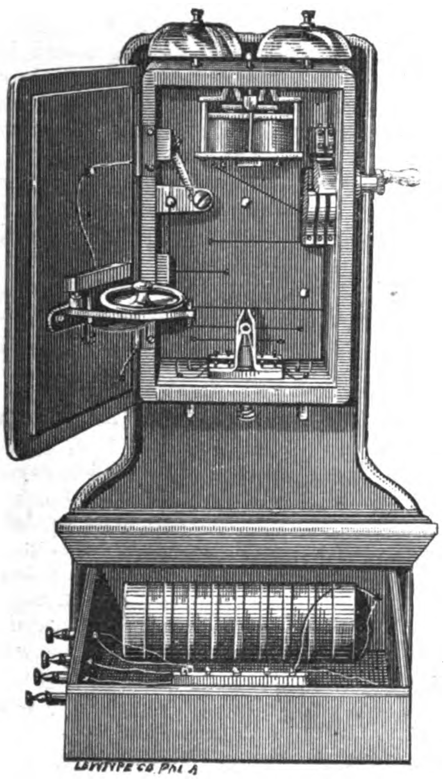

FIGURE 8.—Dolbear's Secondary Ringers.

The resistance of Dolbear's receivers is of course very great. One of them, he states, has a resistance of upwards of 10,000 megohms, while its capacity is about 2 or 3 ten-thousandths of a microfarad.

In figure 8 is shown Dolbear's arrangements for call bell, transmitter, etc. The handle, shown near the upper right corner of the figure, when turned rapidly makes and breaks the circuit of a number of battery cells that are placed in the lower part of the box. In this circuit is included the primary wire of an induction coil, seen in the lower part of the figure. The ends of the secondary coil are connected to the main line, and the currents produced therein by induction, consequent on the making and breaking of the primary circuit, traverse the main circuit and ring the bell at the distant end of the line. By means of this exceedingly efficient form of apparatus, call bells are readily rung at distances of over 1,000 miles.

The ends of the secondary coil being connected with the main line the electrical charges are of course sent into the plates of the receiving instrument that is placed in a branch circuit between the terminals of the induction coil.

The ringing of the bell, therefore, at the same time charges the receiving instrument and thereby sensitizes it to its maximum, thus fitting it to act as a delicate receiver when removed from its hook.

The transmitting instrument is attached to the door of the box and is then enclosed when the door is shut. It consists of a shallow box with a modified Reis transmitter in which the platinum points ordinarily employed by Reis are replaced by carbon tips.

CENTRAL HIGH SCHOOL,
PHILADELPHIA, November 25, 1884.

THE BALL UNIPOLAR INDUCTOR DYNAMO.

BY CHARLES WARD RAYMOND, C. E.[1]

(Member N. Y. Electrical Society ; Jun. Member Am. Society C. E.)

I WISH to preface my remarks by saying, I was connected with the Ball Electric Co. for two years, but am not now, and have not been for the past six months.

I shall give in this paper a description of, and a few facts concerning a dynamo machine, about which many remarks for and against have been made, leaving to my hearers to apply any and all theories as to why the machine works, asking them only not to waste their time in trying to find out why it ought not work, assuring them it is a fact it does work, and works well, the opinions of several learned and well-known electricians to the contrary notwithstanding.

The Ball "Unipolar" Inductor Dynamo was invented by Charles Eugene Ball, of Philadelphia, in 1881. In 1882 the first machines were constructed in considerable quantities. This was the machine first brought before the public here, and in Canada and England. A brief description of it may not be out of place. It consists of a long rectangular frame of iron, the sides of which are the cores for the field, around which are coiled the insulated copper field wires. The end pieces, to which are bolted the side bars, serve as supports for the bearings through which the shafts rotate. There are two shafts in the same line, having a common centre bearing of gun metal; a small disc of brass is interposed between the ends of the shafts to secure magnetic insulation. On each of these shafts is mounted an armature of the Pacinotti type. The construction of the machine is such that it has the appearance of having four pole pieces, one on each side of each armature, while in reality there are but two, the other two pieces being neutral, or nearly so, having but the slightest magnetism when the machine is in action, the neutral line being a little to one side of the centre of the pole piece. The armatures of this machine rotate in opposite directions, and the whole machine is coupled so that the current passes successively through one armature, one half of the field, the other armature, and lastly through the other half of field. A diagram of the whole (figure 1) is

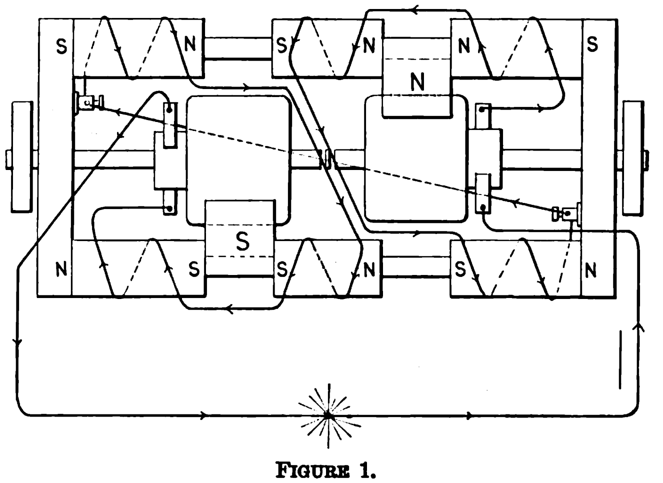

FIGURE 1.

here given. In a report by Mr. Robert Sabine, it is stated, "The effect of this so-called unipolar arrangement, so far as the field is concerned, appears to be that the rectangular soft iron frame is converted into two long electro-magnets, with two poles, only one being presented to each of the rotating bobbins instead of four shorter and proportionately weaker electro-magnets, having four poles, as in the ordinary way, by which two opposite poles would be presented to each of the bobbins."

1 Read by the author before the N Y. Electrical Society, January 14, 1885.

Digitized by Google

There were certain advantages in this form of machine which are evident, it being virtually two independent machines in one. But the disadvantage of *requiring* two belts was sufficient to cause the changes adopted in the newer and later form. This machine was tested in several places, but most exhaustively in London, in March, 1883, by Mr. Robert Sabine, whose recent death cast a gloom over the electrical world on the other side of the ocean, and whose memory will ever be cherished by those who love truth for truth's sake; the character of whose work is his greatest monument.

The next form of machine was similar to the above, with the exception that the spaces occupied by the neutral pole pieces were filled up with the field wires. Then followed the present form of dynamo, of which figure 2, is a perspective view. In this the armatures are mounted on one and the same shaft, consequently rotating in the same direction. The field cores are round bars of soft iron, and the field wire is distributed over four bars, two above and two below. The pole pieces, two in number, one above one armature, and one below the other armature, are fastened by bolts to the field bars. The end plates are of soft iron, and to them the round field bars are bolted. This form of machine, while compact, is exposed on all sides, all parts are easy of access, and the whole easily taken apart or put together. The following features strike me as peculiarly favorable in this dynamo.

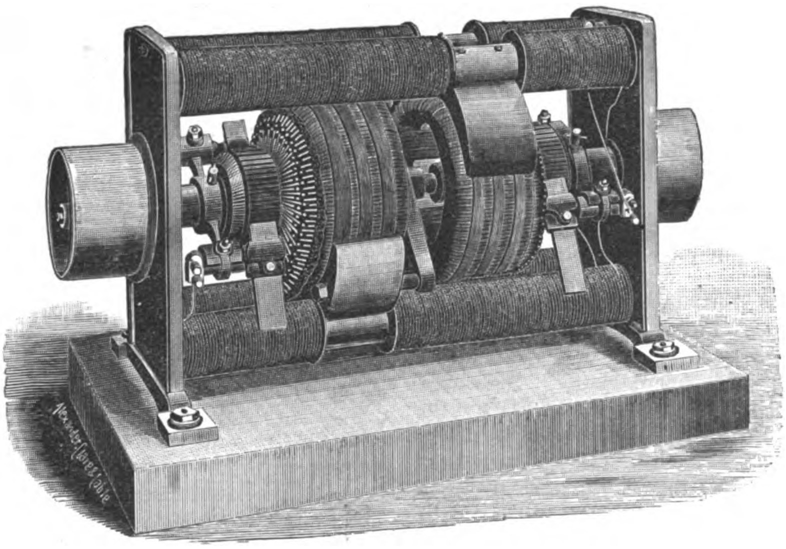

FIGURE 2.—The Ball Unipolar Inductor Dynamo.

By a glance at the construction of the machine the attention will at once be fixed by the comparatively small size of the machine for the results attained, its general compactness, its freedom from complication, or parts more ornamental than useful, and the complete exposure of all vital parts to a good circulation of air.

By compactness is obtained maximum result with minimum space occupied, or minimum size of dynamo, while at the same time every portion of the machine is easy of access.

By simplicity, low cost of manufacture, both in regard to labor and material, is secured. Economical running and freedom from repairs are also accomplished through the lack of any unnecessary mechanism.

In the peculiar arrangement of two armatures or bobbins, each revolving under the influence of but one pole, more is obtained than would at first appear to the casual observer.

It will be seen that on each armature there is a certain amount of copper wire; this amount is much less than is ordinarily wound on a single armature used in a bipolar dynamo of the same capacity; or, in other words, the amount of copper wire on the single armature of a bipolar dynamo is in the "unipolar" distributed over two armatures. This enables two very important results to be obtained; first, the thickness of the section of the armature coils is very much less than in the "bipolar" (about one-third), which, of course, brings the iron core of the bobbin, around which the wire is wound, much nearer the pole-piece; and as the intensity of the magnetism or magnetic effect varies inversely as the square of the distance of this core from the pole-piece the gain in magnetic effect is evident, the nearer the two can be brought together, the greater is this effect. Secondly, by this reduction in the thickness of the covering of the iron core, or the wires wrapped around it, and the greater surface exposed to the air by reason of the two armatures, it is very evident that any heat generated in the core and wires can more easily and rapidly radiate, and the temperature of the armature be kept at a low point. That this is accomplished, is a fact, and the temperature of the "unipolar" armatures is such that it never becomes sufficiently high to char or carbonize the cotton covering of the wires in the armatures.

The form of the field, straight bars of round iron forming part of the frame, is such, that its cost is barely more than the cost of the metal; and as the field wires are wound on the lathe on cylinders of thin metal, it is only necessary to slip them on the bars, make the connections, and the field is complete. This renders repair or change in the field a small item. By the use of wrought or soft iron throughout, the maximum magnetic effect is obtained with a minimum weight of metal. If weight of ironwork be of no importance, the first cost of labor and material can be somewhat reduced by the use of cast iron, but the weight is thereby increased about 25 per cent., with a slight sacrifice of compactness.

Among other good points in mechanical construction may be noticed the long bearings at each end, the gun metal centre bearing supported by the pole-pieces, and a driving pulley on either or both ends. The brushes are arranged so as to be easily removed, or shifted in their holders singly, or as a pair, around the commutators. It will also be noticed that the brushes, of which there are four, are very light and simply constructed, consisting of six or eight strips of very thin (about $\frac{2}{100}$ inch) hard rolled copper, about 6 inches long and $1\frac{1}{2}$ inches wide, simply soldered at one end; inexpensive in first cost, and as they wear very slowly, owing to freedom from sparking, and light pressure, they are a small item in the running expenses. The contact pressure of these brushes is so light as to cause comment; and the little or no sparking enables the commutators to be kept always in excellent condition, with the smallest possible amount of wear.

The method of fastening the wires from the armature to the commutator sections is simple and effective. The wires are easily removed if necessary. The open spaces between the connecting pins or radiating spokes afford free air circulation, and the distance of the pins apart is sufficient to prevent short circuiting by copper dust, which is never present in any quantity, owing to the light contact of the brushes and consequent small amount of copper dust formed.

The method of winding the armatures is such that it enables an armature to be rapidly, hence cheaply wound, and also does away with all crossing of wires in the different sections, the end wires of each section being both outside wires.

I would call your attention to one feature in the construction of these dynamos which has its importance, and that is the facility with which the dynamo can be taken to pieces, and as easily put together, all machines of the same class having their parts interchangeable. By removing

Digitized by Google

four screws in one end plate, which is then detached from the four magnet bars, the end plate may be then pulled off; by removing two bolts which support the centre bearing, the shaft, armatures, and commutators are removed; by loosening a screw in each armature, these, with their commutators are slipped from the shaft; by unscrewing the four screws in the remaining end plate, the field magnets are taken out, and the whole machine is now dismantled. Each armature is mounted on a brass hub, from which, like the spokes of a wheel, radiate 6 to 12 screws (the number depending upon the size of armature). These screws abut against metal shoes, the screws forcing the shoes against the interior of the armature thus forming a firm support for the same. The hub is fastened to the shaft by a key, and kept in place by a set screw. These radiating screws enable the armature to be nicely balanced on the shaft, and at the same time offer no obstruction to the free circulation of air. This hub of brass is extended, and to it is fastened the commutator, enabling the armature and commutator to be taken off the shaft without disturbing the balance or centering. The end bearings are of gun-metal, long, carefully centered, and fastened to the end plates by a single large nut on the outside. The brush holders are fastened, so as to be easily removed, to two arms extending from a cast iron ring, and diametrically opposite; this ring turns freely about the gun-metal bearing, and has a thumb-screw, by means of which it can be set in any position; it is also provided with a simple grease catching device. The two pole pieces are fastened by countersunk screws to the round magnet bars, and are bored out to proper size, such that the armatures shall just clear them in revolving; this clearance is never greater than $\frac{1}{16}$. The armatures are carefully bound by three or more bands of finest steel wire, wound under strain, and made hot by the friction of this strain, and finally carefully soldered, making a strong and neat band of metal.

The commutators and armatures have a great number of sections, hence the current is as nearly continuous as is possible to obtain.

In the construction of the armatures the same simplicity of mechanism is maintained. One noticeable and important feature must not be overlooked, the perfect insulation of the electrical circuit from the frame work. As above stated, the armature is firmly fastened to the shaft by the adjustable spokes or screws, 6 to 12 in number, radiating from and working in the hub of brass. These screws are capped by shoes of metal, which are again capped by shoes of well seasoned wood. Between the wood and the inside of the armature are two or more thicknesses of canvas. By means of the adjustable spokes the shoes are firmly pressed against the inside of the armature, and the armature thus rigidly fastened to the hub, accurately centered and thoroughly insulated.

As previously stated, this hub is keyed to the shaft, and kept from sliding endwise by a set screw. The hub is extended through the commutator, which is also fastened to the hub, independently of the armature, and hence no strain is brought upon the wire connections. The core of the armature is composed of soft iron, properly and thoroughly well insulated.

The sections are wound, as in the Gramme armature, and the ends of the sections connected in series with the corresponding sections of the commutator by screws in each post on that section. The coupling of this form of machine is similar to that shown in the first diagram, changed only to enable the two armatures to rotate in the same direction, as shown in the diagram figure 3.

Before giving electrical and other details, I will mention some of the adaptations which are peculiar to this machine. The dynamo can be used to maintain two independent circuits of the same or different potential. It can be used to transform currents of a high potential into currents of low potential and vice versa. In the case of either arc or incandescent, one half the number of lamps can be operated without corresponding waste of power. As I have been asked whether this dynamo can be run if coupled, so as to produce two poles of like polarity, *i. e.*, two north or two south poles, I will say yes, it can and has been done, the

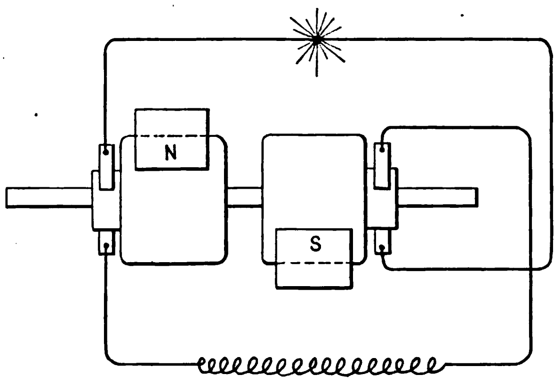

FIGURE 3.

other poles appearing in the end frames. As a fact, there is a loss of about two-thirds of the current, half of the magnetism being thrown into the end frames, becomes not only idle, but reacts through the shaft, and forms poles of like polarity, hence opposed in effect. It is but an experiment which has no practical use.

Another fact has been seriously questioned and doubted, but I think I may safely say *only* by those who have not tried the same for themselves, and that is the existence of a line of neutrality in the field bars, or line of no magnetic force, attractive or repulsive. That this is a fact, I call upon the president to verify, and it is situated a little to one side of the centre of the field magnet, opposite the pole piece. I do not allude to the armature, which shows two strong poles.

As to advancing any theory regarding this arrangement of one pole to each armature, I beg to be excused; but I will say that the following seem to me some of the chief reasons for its high efficiency as a generator.

The distribution of a given amount of wire over two armatures, thus bringing the *core* of the armatures nearer the pole pieces than is possible in the "bipolar" machines, and the consequent thin covering or small number of layers of wire over the core, thus enabling a more rapid dissipation of heat, and also a higher peripheral velocity of the core under the same circumstances (the periphery of the core being further from the centre of rotation). I call your attention to this section of wire cut from the armature of a well-known make of dynamo of the Gramme type.[2] The dynamo from which this large and charred section was taken had been running about 2,500 hours, giving 800 volts, 8 ampères. It will be seen it is 13 layers deep, No. 15 wire (B. & S. gauge) with three layers of cotton covering, which may have been paraffined. Its dimensions are, 10 ins. long outside, $6\frac{3}{4}$ ins. inside; $3\frac{3}{4}$ ins. deep outside, and $1\frac{1}{4}$ ins. inside. This weighs $20\frac{1}{2}$ ozs. 100 sections = 2050 ozs. = 128 lbs. It will be seen the first five layers are badly charred, the charring decreasing as it nears the outer layers, disappearing entirely at the outside. This would point to the core as the point of highest temperature, which was, however, charred only on the outside. There are about 110 ft. of wire in each of these sections.

Now compare it with this section[3] from a Ball "E" dynamo which has run 2,500 hours, with 950 volts 8 ampères. This is five layers deep, No. 17 wire (B. & S. gauge) covered with two layers of cotton, but no paraffine or other insulating compound. Each of the armatures contains 90 sections, and each section about 36 ft. of

2. The sample of wire here exhibited, was so thoroughly charred that insulation was destroyed.
3. This sample of wire bears no evidence whatever of any heating effect.

Digitized by Google

wire. Its dimensions are, $6\frac{3}{8}$ ins. long outside; $5\frac{5}{8}$ ins. inside; $1\frac{7}{8}$ ins. deep outside, and $1\frac{1}{8}$ ins. inside. Weight, 4.1 ozs.; 90 sections = 23 lbs.; 180 sections = 46 lbs. I think the comparison is considerably in favor of the Ball system, both machines being about the same capacity; the former 18 lamps, the "Ball" 20 lamps. Again, in the core of each armature of the Ball dynamo, there is about the same amount of iron as is in the single armature of a "bipolar"; thus enabling the machine to carry a greater current before becoming saturated. This may, it seems to me, explain why the capacity of a Ball dynamo can be nearly doubled without danger, and also may account in part for the low temperature of its armature when in action, particularly noticeable at high speeds, there being double the amount of mass in the cores of the two armatures combined.

The following comparisons of weight of material on machines of different systems may be of interest, and if they are not close approximations to the truth, I need only allude to the great difficulty in obtaining such facts as my apology for any errors. In the case of the Ball dynamos I can vouch for their accuracy.

	"Unipolar."	"Bipolar."
Weight of copper wire required (per arc light)	7 to 10 lbs.	25 to 40 lbs.
Weight of other metal, iron, &c., do	22 to 42 "	15 to 180 "
Total weight of all, do	39 to 50 lbs	100 to 220 lbs.

NOTE.—The total weight of machines other than the "Ball," are in the main taken from the catalogues of the various companies.

I wish to avail myself of the opportunity here offered of denying a statement made by an electrician prominent enough to be more careful in his *misstatement* of facts so liable to injure others; and for fear it may be thought I mean some one of the many who applauded the discourteous, certainly untruthful statement, I will say, I allude to the report of the remarks made by Prof. Silvanus P. Thompson, before the National Conference of Electricians at Philadelphia, as printed in the *Electrical Review* (London) December 13, 1884. After calling attention to the "bad design" of the machine, and admitting with much condescension that "it *may* work," because "it is hard to have a dynamo machine with a Gramme ring in it that does not work," the professor goes on to say that the lines of force "spread out into the air": "I examined this machine once in England" (probably just as he examined it here), "and I saw a similar machine in your exhibition;" and as a proof of his statements adds: "It seemed to me to be a striking commentary on the omission of the pole piece that over that machine *alone* of all machines in the Exhibition, there was a sign which ran: '*Do not approach this dynamo for fear of magnetizing your watches*'." ("Laughter and applause.")

The truth is this: at the beginning of the Exhibition the management warned the public against dynamos, by tacking up or suspending over each dynamo stand a card saying: "Dynamos will magnetize watches. Keep away." In a very short time the only cards allowed to remain, was one over the "Edison" (which the professor evidently did not see), and one over the Ball dynamo. I may also say there was an establishment close to the entrance to the exhibition which advertised to take charge of watches of visitors, *probably for fear of being damaged by the Ball dynamo.*

This may seem a trifling matter; so it would be were it the only instance of a deep-rooted prejudice, or unscientific ignorance of facts which has been published several times against the Ball dynamo, in addition to similar remarks at its expense made at this conference of scientific men. Contrast the remarks of this distinguished English scientist with the manly tone of Prof. Nipher, who virtually replied to Prof. Thompson: "It occurs to me to say a few words in regard to an unfortunate machine which has been referred to several times, and which I saw the other day for the first time. It has two armatures and only two pole pieces. I was as much astonished as anybody could be when I saw it, but when I was informed that it weighed less than one thousand pounds, and maintained a high strength of current, I thought it worth while to investigate what the machine would do, before we said too much about how it worked."

Now I would like to ask why has so much antagonism been manifested against the Ball dynamo? It cannot be said the machine is bad, for every test made upon it has proven the fact to be otherwise. It cannot be said the machine does not work well and economically, for the most careful tests place it second to none in electrical economy. It cannot be called an expensive machine, for you can ascertain the fact for yourself, that there is none cheaper to buy. It must cost lest than many others, as there is less material and no more work upon it.

I remember a little incident which occurred two years ago, when I represented this machine in London. I received a visit from Mr. Latimer Clark, an eminent English Electrical Engineer. Almost his first words to me were: "Mr. Raymond, I don't like the looks of that machine; it is built wrong, constructed upon entirely wrong principles, and I would almost be willing to stake my reputation that it won't work." I said nothing, but allowed him plenty of time to examine the dynamo. When I started the machine and closed the circuit the machine was doing its best, and the six fully 2,000 c. p. arcs lit up the shop, the gentleman was startled; he looked first up at the lamps, then at the dynamo; after a little he put his hand to his head and said: "I am vexed, very much vexed." "Why," I asked. "Because," said he, "all my experience and practice of the past thirty years teaches me that that machine is built wrong, wound wrong, ought not to and cannot work, but, confound it, it does, and very nicely, too!" Mr. Clark today is one of the few prominent English electricians who admits the good qualities in the Ball dynamo, and I trust he will pardon me for telling tales out of school.

I cannot understand why, if a test is made disproving the antagonistic statements, the tests are questioned, no matter what the integrity of the expert may be. If test after test is made, each confirming the previous ones, still no admission from the opponents. I should not be so much surprised if these remarks, this prejudice, was confined entirely to slow-going Britain; but even in this country, noted for its quick appreciation of merit, do I find this prejudice, and I regret to say only in scientific circles, so opposed as it is to all true scientific thought. It recalls the old saying: "History repeats itself," and painfully sug-

Digitized by Google

gests those well known instances of the infallibility of scientific men. Let me in closing quote one or two of those instances which are now historical.

Wood, in 1825, wrote: "Nothing can do more harm to the adoption of railroads than the promulgation of such nonsense as that we shall see locomotive engines traveling at the rate of 12, 16, 18 and 20 miles per hour."

Dr. Lardner, an eminent English mathematician, published a treatise to prove that no steamship could ever cross the Atlantic ocean, and the steamer "Sirius," a few weeks later, brought the first copies of his pamphlet to America."

"Babinet, the French calculator, declared no telegram could ever be transmitted through the Atlantic ocean to America." Edison did not escape entirely intimations of insanity when he first began to talk electric light, and Sir Humphrey Davy himself "gave it as his opinion that it would be as easy to bring down a bit of the moon to light London as to succeed in doing so with gas!"

Brooklyn, N. Y., Jan. 13, 1885.

The following tests and details of the Ball machines are from reports and records as mentioned.

From a report made by Robert Sabine, Esq., C. E., in March, 1883, upon the earlier form of the Ball dynamo, since which time great advances have been made in regard to efficiency, total weight, and weight of copper on machine:

Current in circuit	15.0 ampères.
Difference of potential between terminals	195.0 volts.
Resistance of dynamo (hot)	4.5 ohms.
Expended upon machine for electrical work	5.68 horse power.
Accounted for in outer circuit	3.92 "
" " in inner "	1.35 "
The proportion accounted for electrically	93.1 per cent.
Accounted for in lamps	69.2 "

Photometric measurements on *one lamp* out of six, as follows:

Current in lamps	13.9 ampères.
Potential difference	40.1 volts.
Accounted for in lamp	0.75 horse power.

Illuminating effects were as follows:

Position of arc with regard to photometer.	Observed. Standard candles.	Illuminating Power. Per 1 h.p. accounted for in the lamps. Standard candles.
22 deg. below	602	802
11 " "	626	835
Horizontal	887	1,183
11 deg. above	1,213	1,617
22 " "	1,831	2,441
31 " "	1,859	2,479
35 " "	1,690	2.253

The following are records of tests taken in New York City by the Ball Company—1883:

TEST OF C NO. 0.

(Style of machine no longer manufactured.)

Weight of dynamo	505 lbs.
Copper wire on fields	103 "
" " armatures	48 "
" " machine	151 "
Diameter of armature	11 inches.
Resistance, field (cold)	1.35 ohms.
" armatures (cold)	1.80 "
" machine (cold)	3.20 "

Running 8 arc lamps, 2,000 candle-power nominal—

Revolutions	1,465 per minute.
Current	18 ampères.
Electromotive force, external	251 volts.
Gross horse-power	5.50
Gross efficiency	92 per cent.
Net "	$79\frac{3}{10}$ "

With 7 arc lamps—

Revolutions	1,425 per minute.
Current	13.5 ampères.
Electromotive force, external	240 volts.
Gross horse-power	5.60
Gross efficiency	92 per cent.
Net "	$78\frac{3}{10}$ "

Running 6 arc lamps—

Revolutions	1,300
Current	13.1 ampères.
Electromotive force, external	219 volts.
Gross horse-power	5.0
Gross efficiency	93.5 per cent.
Net "	78.1 "

By *gross horse-power* is meant the horse-power given to generate the current, and does not include friction of dynamo.

TESTS OF C NO. 5.

(Style no longer manufactured.)

Weight of dynamo	500 lbs.
Copper wire on fields	84 "
" " armatures	49 "
" " machine	133 "
Diameter of armatures	11 inches.
Resistance, fields (cold)	1.62 ohms.
" armatures (cold)	1.88 "
" machine (cold)	3.5 "

Running 9 arc lamps (not up to candle-power) 2,000 c. p.—

Revolutions	1,465
Current	12.5 ampères.
Electromotive force, external	250 volts.
Gross efficiency	92 per cent.
Net "	$77\frac{3}{10}$ "

Running 8 arc lamps, 2,000 c. p.—

Revolutions	1,430 per minute.
Current	13.4 ampères.
Electromotive force, external	246 volts.
Gross efficiency	92 per cent.
Net "	$76\frac{3}{10}$ "

TEST OF INCANDESCENT DYNAMO. SERIES WOUND, ARMATURES AND FIELDS IN PARALLEL.

Weight of machine	525 lbs.
Copper wire on fields	102 "
" " armatures	49 "
" " machine	151 "
Resistance, fields (cold)	.084 ohms.
" armatures (cold)	.112 "
" machine (cold)	.200 "
Diameter of armature	$11\frac{1}{4}$ inches.

Running 60, 20 candle power, 50-volt., 1 ampère lamps.

Revolutions	1,210 per minute.
Current	60 ampères.
Electromotive force, external	52 volts.
Gross horse-power	5.55
Gross efficiency	93 per cent.
Net "	$75\frac{3}{10}$ "

TEST OF 20 ARC LIGHT DYNAMO.

(Style no longer manufactured.)

Weight of machine	1,262 lbs.
Copper wire on fields	180 "
" " armatures	69 "
" " machine	249 "

Running 20 arc lamps and with 1.1 ohms. line resistance.

Revolutions	1,300 per minute.
Diameter of armatures	12 inches.
Current	13 ampères.
Electromotive force, external	837 volts.
Gross efficiency	91.5 per cent.
Net do	82.2 "

"E" MACHINE.

(Style now manufactured.)

	H. P.
20 lights—Revolutions 1,380.	
(a) Total actual belt h. p.—required with full load	12.85
(b) " " " " on normal short circuit	2.56
(c) " " " " for friction	0.43
(d) " " " " " air blast	0.09
(e) Electrical h.p. in external circuit (8.05 ampères, 956 volts).	10.31
(f) " " of all the circuit measured by dynamometrical pull on reproduced current[5]	12.01
Resistance of machine .22 ohms.

LITERATURE.

REVIEWS.

The Quadruplex, by WILLIAM MAVER, JR., and MINOR M. DAVIS, *With chapters on the dynamo-electric machine in relation to the Quadruplex; the practical working of the Quadruplex; Telegraph Repeaters and the Wheatstone Automatic Telegraph by* WILLIAM MAVER, JR. New York: W. J. Johnston, 1885.

IT will no doubt be within the memory of those who were engaged in telegraphy 25 or 30 years ago, that a telegraph operator was then considered hardly competent to fulfil the duties of his position, unless he understood and could perform with his own hands almost every kind of work pertaining to the service. It was necessary for him not merely to be able to transmit and receive communications over the wires, but to take in messages over the counter, and in many cases to act as his own delivery messenger and to keep his own books; he was moreover expected to attend to his own batteries, both main and local, to keep in repair a certain section of the main line, and build or rebuild it when necessary, and even to repair his own instruments unless perchance the damage happened to be of a serious character. Hence we find that the more intelligent of the early operators were men thoroughly well-informed in relation to all the details of the service, who could satisfactorily perform the duties of any position from messenger-boy up to general superintendent.

With the enormous development and growth which the modern telegraph system has attained, the service has become more and more specialized. The division and subdivision of labor plays at the present day a no less prominent part in telegraphy than in almost every other branch of business. It is a source of satisfaction to us to observe that a corresponding change is evidently taking place in the character and scope of telegraphic literature. Voluminous and expensive general treatises covering the entire field of telegraphy no longer possess their former importance or value, for under the present, and still more under the future organization of the service, no one person can be expected to become familiar with the details of every department of practical telegraphy. Hence there exists a real want which thus far very little has been done to supply; that of special treatises of moderate size and cost, written in plain and intelligible language by authors who not only have the necessary practical knowledge, but what is equally important, the ability to impart it in a clear and comprehensible mannner to others. This is precisely what the authors of the present work have endeavored to do for the practical operators employed in working certain special classes of modern telegraphic apparatus, and we may as well say at the outset, that they have not only shown themselves eminently well qualified for the particular work they have undertaken to do, but have executed it with a conscientious thoroughness that leaves little to be desired.

The first chapter contains an abridged historical sketch of the quadruplex, mainly compiled from Prescott's *Electricity*, showing the numerous modifications which were undergone by the apparatus during what may be termed its experimental period, extending from its first introduction on the line between New York and Boston in 1874, down to the time when the present standard plant was arrived at, which was some 5 or 6 years ago. They then take up the apparatus in its present form and proceed to set forth its principles, its construction and its mode of operation. The manner in which the particular elementary facts of electricity and magnetism upon which the operation of the quadruplex depends,

The following tests of an "E" dynamo constructed nominally for supplying 10 arc lamps were made by H. Alabaster, Gatehouse & Co., in April 1884. They agree very nearly with the results obtained by Mr. Robert Sabine from an old style machine a year previous.

The potential difference of the machine between terminals was measured by the condenser method, a Clark's standard cell being employed for comparison of electromotive forces. Two Siemens' electro-dynamometers, one of these being supplied by us, indicated the current strength, each instrument giving identically the same readings. The external resistance, and that of the machine, were measured immediately after each test. Horse-power measurements were taken by means of a Morin transmission dynamometer and a Prony brake.

Countershafting was placed between the dynamometer and the dynamo, the former being so arranged as to run at about the same number of revolutions per minute for varying speeds of the dynamo, this being accomplished by using pulleys of different diameter on the latter. The Prony brake, which was balanced, gave admirable readings, there being but a difference of 2 ounces in the weight applied at the end of the lever in 3 distinct measurements.

The principal test was made as nearly as possible under the same conditions of speed and current as that taken previously by the Silvertown electricians. The results obtained by us are tabulated as follows:

No. of Test.	Current in Ampères.	Resistances in Ohms.			Electrical Work.				Mechanical Work. Prony Brake.			Revolutions of Dynamometer.	Morin Dynamometer.			Percentage of Efficiencies.				Revolutions of Machine. Average.
		External R—r.	Dynamo r	Total R	Watts $C^2 R$	H.P. External.	H.P. Internal.	H.P. Total.	Weight in lbs.	Length of lever, feet.	H.P. absorbed.		Pull machine loaded. Kilog.	Pull machine empty. Kilog.	H.P. Calculated.	Conversion.	Appearing in External Circuit.	Commercial calculated from absorbed H.P.	Commercial.	
A	8·07	56·0	17·15	73·15	4764	4·888	1·497	6·385	....	....	....	378	69	14	6·83	93·5	76·5	71·5	63·3	[illegible]
B	8·07	68·8	16·93	85·73	5583	6·00	1·479	7·479	... ...	....	....	365	89	20	8·28	90·3	80·3	72·4	....	[illegible]
*A	8·07	59·33	17·12	76·45	4980	5·179	1·494	6·674	13·94	2	6·9	384	75	18	7·16	93·2	77·6	72·3	67·3	1300
													Prony Brake			96·7	"	75·0	70·0	......

OBSERVATIONS.—Test *A is nearly a reproduction of test A, and to it was applied the Prony brake; in 3 separate measurements at varying intervals the weights applied at the end of the lever were 13 lbs. 15 oz., 13 lbs. 14 oz., and 14 lbs. respectively. The formula is $\frac{n \times L \times x}{5252}$ where n is the number of revolutions per minute, L the length of lever, and x the weight. The formula for the Morin transmission dynamometer is $\frac{1\cdot5 \times K \times S}{60 \times 76\cdot04}$ where S is the speed and K the indicated pull in kilos on the dynamometer less the pull when the circuit is open. When the Prony brake was employed to measure the absorbed h.p. the Morin instrument was used as an indicator. Thus, when electrical work was being produced with the machine running at 1,300 revolutions the Morin indicated 75 K, this pull was then reproduced in the Prony brake test with the machine running at the same speed. The commercial efficiency of the machine is calculated both from the absorbed h.p. alone and with the addition of the h.p. which the machine requires to run at 1,300 revolutions unloaded = 0.54 h.p. Test B, at a higher speed, was taken at the suggestion of Mr. Ball. In test *A the Prony brake was resting by its own weight upon one of the pulleys of the dynamo when doing electrical work, and also when running empty. The external circuit was, in each case, made up of a wire resistance.

Digitized by Google

are explained and illustrated, is worthy of the highest commendation. This is especially noticeable in reference to the divided circuit, the differential or neutralizing electro-magnet and the condenser.

In the succeeding chapter the Stearns duplex is first explained, and then the polar duplex. These explanations prepare the student to comprehend without difficulty the essential principles upon which the operation of the quadruplex depends, it being, from the point of view taken by the authors, simply a combination of these two duplex systems.

Prior to the year 1881 the numerous quadruplex lines radiating from the Western Union Telegraph building in New York were operated by voltaic batteries, but at that time certain modifications were made in the apparatus to enable it to work upon currents produced by the dynamo-electric generators which had already been introduced by Stephen D. Field for operating the single circuits. A description is accordingly given of the system of dynamo-electric generators now in use by the Western Union company in New York, together with a full explanation of the manner in which the lines are operated in connection with them. This description is exceedingly good and is of much professional interest, having never before appeared in any treatise on telegraphy. It is followed by an equally good description of the modified quadruplex apparatus, as adapted to the new system.

This portion of the work is completed by a chapter on the practical management of the apparatus, in which the numerous faults—or, as they are technically termed, "bugs"—which infest the quadruplex (and it is not too much to say that these electrical insects are numerous and troublesome) are pointed out, their causes explained and their remedies set forth. The most cursory examination will show that this chapter was written by one who thoroughly understands the subject. It is the work of a "practical man" in the best sense of the word, and is skilfully addressed to the comprehension of the average operator. We cannot forbear to quote the final paragraph of this chapter, for, to use a phrase more expressive than classical, "we have been there ourselves."

It would undoubtedly add much to the successful handling of the quadruplex if every one connected with it would frankly state the cause of trouble, when he has found it, to the operator or person in charge at the other end. The latter has seen the symptoms occasioned by the trouble. If he were at once notified as to the exact nature of the fault he would be able at once to direct the distant station to the seat of trouble when next the same symptoms should manifest themselves, and thus time would be saved. Instead of so doing, it has become almost a rule for every manager to hide any trouble happening in his own set, and merely to say that probably a loose wire "shook out," or something equally vague. This pernicious custom is probably due to the fact that some superintendents require so many explanations as to the reason why such and such trouble was not obviated, or not discovered sooner, that a manager rarely allows a fault to be definitely located in his office more than once. It is thus, perhaps, an open question whether it is really to the benefit of the service that managers, who, as a rule, are not apt to wilfully allow trouble to occur, or to sit idly by when it has occurred, should be held so strictly to task.

The chapter on repeaters possesses the same excellent qualities as those on the quadruplex. The general principles on which the working of the combined circuit depends are first laid down. The descriptive portion of the text is wisely confined strictly to the apparatus in every-day use, viz., the Button, the Milliken and the Toye repeaters. A brief but sufficient explanation is also given of certain special plans of repeaters for combining single circuits with duplexes and quadruplexes. The directions for managing or adjusting the several forms of repeaters are not very lengthy, but appear to be sufficient. A chapter on the Wheatstone automatic system, which has already gained something of a foothold in the United States, and which will not improbably come into more extensive use in the future, completes the volume.

It is seldom that we have examined a work of this kind in which there is so much to commend and so little to criticise. In fact, the work is so simple in its aim and so unpretending in its execution as to disarm unfriendly criticism. It is nevertheless essentially original, not only in its subject-matter but in its treatment. Even that *bete noir* of the telegraphic student, "algebra," is conspicuous by its absence.

The volume is profusely illustrated with original diagrams, which have been exceedingly well drawn by Mr. Mailloux, and these for the most part are very fairly engraved. There is at least this to be said for the illustrations, that they are actually illustrative of the text; in fact, it would be difficult to find one of which it can fairly be said that it has been introduced solely for pictorial effect.

The paper and printing of the work are not all that could be desired in a treatise of this kind. This is the more to be regretted as other works issued by the same publisher—for instance, Lockwood's *Information for Telephonists*—have been quite unexceptionable in this respect.

There is a fine opportunity at the present time for some enterprising publisher to bring out a series of inexpensive practical manuals of the same general character as the book under review, treating of the different branches of the telegraphic service, somewhat upon the plan, for example, of Hartleben's admirable *Elecktro-technische Bibliothek*. If the authors were wisely selected such an undertaking could hardly fail to be successful.

NEW PERIODICALS.

Industrial America; a popular record of progress in the arts and sciences. Published every other Saturday by W. J. Johnston, New York.

The subjects which come within the scope of this journal are so numerous, that an ordinary mind would perhaps hesitate before attempting to cover "the entire field of industrial progress." The development of industry in modern days tends rather toward its division into numerous branches, each of which as its importance becomes recognized, is represented by one or more periodicals, devoted especially to its chosen mission. There can be no doubt, however, that from this vast field, sufficient new and interesting matter may be obtained to more than fill all the space which a publisher can devote to its presentation. The reader who looks to illustrated mechanical literature for entertainment should be well satisfied with the selection of topics treated in this publication.

CATALOGUES AND PAMPHLETS RECEIVED.

Buckeye Engine Company, Salem, O. Descriptive catalogue devoted more especially to their excellent automatic cut-off engine, but containing information of value to every person interested in steam power. Elegantly printed and illustrated.

I. W. Colburn & Co., Fitchburg, Mass. A very complete description of the dynamos, arc and incandescent lamps of various patterns manufactured by this well-known firm. Fully illustrated and giving an excellent idea of the apparatus sold by them, which includes small dynamos for experimental and electro-plating purposes.

Waldumer Electro-Magnetic Brake Co., Cincinnati, O. Annual report for year 1884. The pamphlet contains testimonials from practical railroad men, commending the working of the apparatus in actual use.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.

The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.

In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.

Sketches and drawings for illustrations should be on separate pieces of paper.

All communications should be addressed EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

HEATING AND LIGHTING RAILWAY CARS BY ELECTRICITY.

[29]—Is there any reason why the cars of the New York elevated railways cannot be heated and lighted as well as propelled by the electric current from a central station? At the Philadelphia exhibition I noticed that a rack full of incandescent lamps in the exhibit of the Brush electric company, gave out a great amount of heat, giving one, in fact, the feeling of standing in front of an open fire-place, thus showing that it is at least possible to warm one apartment in this manner. H. J. C.

NEW YORK, Dec. 25th, 1884.

It was proposed by Edison, 3 or 4 years ago, to light an electric railway car with the same current used to propel it. There is apparently no reason why it may not be done successfully. With regard to heating, the question is different, as the cost of the method is so great as to forbid its practical use. The original, energy of coal, is converted first into steam, then into motion

Digitized by Google

then into electricity, and then back again into heat. At each conversion a considerable amount of energy is lost. By generating steam, and warming by direct radiation, it is possible to utilize as much as 60 per cent. of the total heat energy contained in the coal consumed, while by the electrical method, not more than 5 to 10 per cent. could possibly be realized. It is said that M. de Meritens is now experimenting with electrical foot-warmers in Paris, for railway use. The following table shows the losses by conversion :

TABLE SHOWING HEAT UNITS PER LB. OF COAL, AND PER CENT. UTILIZED IN STEAM-ENGINES, AND UNITS AVAILABLE FOR HEATING BY ELECTRICITY. (R E. Crompton.)

	Total heat units.	Per cent. utilized.
Heat units per lb. of coal, mean of 97 kinds. (British government experiments)..........	13,006	100
Units available in evaporation of water. (British government experiments)	8,033	62
Units in horse-power, best steam-engines. (1 5 lbs. per h. p. per hour)......................	1,715	13.2
Units in horse-power. Good average commercial steam-engine. (3 lbs. per h. p. per hour)........................	857	6.6
Units available in heating coil in external circuit of good dynamo, utilizing 70 per cent. of h. p., with 1-5 lb. engine..	1,200	9.25
do. do. with 3 lb. engine.............	600	4.6

[This table shows that indirect heating by electricity must necessarily be from 7 to 13 or more times as costly as direct heating with steam, in the mere matter of coal, to say nothing of the increased cost of plant and attendance.—EDITOR.]

CORRECTION IN TABLE OF ELECTRO-CHEMICAL EQUIVALENTS.

[30.]—I was much interested in the communication of Mr. Geo. B. Prescott, Jr., page 7, January number of your journal. There are, however, some mistakes probably arising from want of care on the part of the author, which are quite misleading. Columns 6, 7, 8, and 9, for Al. and Mg. should read :

	Col. 6. (q.)	Col. 7. (w.)	Col. 8. (Log. q.)	Col. 9. (Log. w.)
Al.........	10583.00	.34018	4.0245939	$\bar{1}$.5317086
Mg.........	8040.00	.44747	3.9055411	$\bar{1}$.6507614

The table is undoubtedly a very useful one with the exceptions of above. EWING MCLEAY.

Greencastle, Ind., Jan. 18, 1885.

QUESTIONS AND ANSWERS.

[51.]—**Electromotive Force and Potential.**—S. B. T., Phila., says: 1. I am studying Sprague's *Electricity* and find his definitions of potential and E. M. F. so obscure as to be wholly unable to comprehend them Will you please explain these terms and their difference? 2. Is E. M. F. the cause or effect of electricity? 3. Is the difference of potential the same between any 2 points in a conductor, if the points are equally distant from each other? Please answer plainly as there are many who are ignorant of these same terms. **Ans.**—1. A full explanation of the difference between potential and electromotive force is given in vol. iii, page 140 of THE ELECTRICIAN AND ELECTRICAL ENGINEER, (July, 1884). We do not see how the matter can be explained any more clearly. 2. The cause of electricity is not known. Electromotive force is the cause, not the effect, of an *electric current*. It may be likened to the head or height of water in a reservoir, and potential to the pressure of the water at the bottom of the same reservoir. The strength of a current of water from the reservoir therefore depends upon the pressure, and the pressure depends upon the head. So also the strength of an electric current depends upon the potential, and the potential depends upon the electromotive force. 3. The difference of potential is the same between any 2 equidistant points in a conductor provided the conductor is of uniform resistance. If the resistance of the conductor is the same between any 2 points then the difference of potential between them will be equal.

[52.] **Resistance of Railway Track.**—J. M. McC., New York, inquires how the electrical resistance per mile of a railway track can be computed? **Ans.**—If the rail were continuous its resistance might be computed from its weight per mile, but there are 175 joints in each mile, the resistance of which would depend upon the perfection of the connecting device. The resistance is computed from the weight by means of numerical coefficients, the rule being to divide the coefficient of the required metal by the weight per mile and the quotient will be the resistance in ohms. We give a few coefficients deduced from the researches of Professor Hughes. (Proc. Royal Soc., Dec. 1883.) Best Swedish charcoal iron, 4,252 ; Swedish Siemens-Martin, 5,024 ; soft Bessemer, 5,917 ; hard Bessemer, 6,942 ; crucible cast-steel, 7,772. The Western Union standard for iron wire is 4,884. A line of 70 lb. per yard rail of hard Bessemer steel, would therefore give 70 × 1,760 = 123,200 ; 6,492 ÷ 123,200 = 0.00527 ohms (about $\frac{1}{190}$) per mile. The joints may be so made as not to greatly increase this figure.

[53.] **Nomenclature of Electric Circuits.—Electrical Theories.**—M. C. A., Biddeford, Me., writes as follows : 1. Is a continuous wire circuit from one terminal of a battery out and back to the other terminal called an open or a closed circuit? 2. Which is generally accepted as the correct theory of electricity, the single or double fluid? 3. Do the terms *positive* and *negative* electricity mean differences of potential, or are there 2 distinct kinds of electricity? **Ans.**—1. An open circuit is a circuit which extends from one pole to the other of the battery with the exception of a single break. When the circuit is completed at this break it becomes a closed circuit. A closed circuit is a continuous circuit through which a current flows. Work may be performed either by closing an open circuit, or by opening a closed circuit. 2. Electricity is not at the present day usually regarded as a fluid by advanced electricians, although it is frequently referred to as such in a conventional manner. Whatever it may be, whether a fluid, or a form of energy or a peculiar state of matter, it is certainly single and not double, one and not two. 3. The terms positive and negative are relative and not absolute. Wherever there exists a difference of potential, the point of greatest potential is termed positive and the point of least potential negative. In the same sense, for example, the terms heat and cold are relative and not absolute Heat and cold are not in fact two distinct things, but are merely differences of degree in one and the same thing.

[54.] **Electric Railways.**—S. M., of Mohawk, N. Y., inquires for a cheap publication, showing how railway cars are run by electricity, and particularly how several trains or motors may be run on one circuit at the same time. **Ans.**—Prof. W. E. Ayrton's lecture on Electric Railways, price, 20 cents. is the cheapest ; Dr. Adams's article completed in this issue of THE ELECTRICIAN AND ELECTRICAL ENGINEER is very instructive One of the advantages of an electric railway is that but one motor can run on each section at the same time, thus avoiding collisions.

[55.] **Bichromate Batteries.**—C. E. K., Jr., New Orleans, La., writes that he is using an "automatic" battery, a form of Grenet, with carbons 4½ by 2½ and zincs the same size, in respect to which he inquires :—1. Would a battery with elements half the above size do as well to run a small motor? 2. Comparative efficiency of a battery with only one carbon and a zinc in each cell? 3. Would it be as well to have a carbon cylinder, instead of two plates with a zinc rod in centre? **Ans.**—1. No The efficiency would diminish nearly in proportion to the lessened surface of the plates, as you will find by raising them partly from the solution. 2. We cannot say without more definite data The efficiency however would be much less, when used for a motor. 3. No. The proposed arrangement is better adapted for long circuits of high resistance.

[56.] **Effect of Temperature on Voltaic Batteries.**—W. A. P., Hartwick Seminary, N. Y., inquires : At what degree of cold (Fahrenheit) the following batteries cease to act : Gravity, Daniell, Leclanché, Grove, Grenet, Bunsen and Smee. At what temperature will the gravity battery give the most and strongest current? **Ans.**—We cannot find that any careful determinations have been made as to the effects of temperature upon batteries. All kinds of batteries appear to work most satisfactorily, all things considered, at a temperature of about 20° C (68 Fahrenheit) ; but they do not entirely cease to act even when frozen solid. The different forms of sulphate of copper battery are most easily affected by a fall in temperature, while the nitric acid and bichromate batteries are but slightly reduced in efficiency. The Leclanché cell is not very much affected by changes in temperature.

[57.] **Fixing Magnetic Figures.**—W. C. W., Erie, Pa., writes: —How can I preserve the magnetic curves formed on glass by iron filings under the influence of a magnet? **Ans.**—Coat the glass with a solution of gum-arabic and dry it, before forming the figures. Soften the gum by exposure to steam, upon drying, the filings will be fixed. Such a glass plate may be used in a magic lantern. Another method is to moisten a sheet of white paper with a mixture of 1 part each, saturated solution of ferrocyanide of potassium, and nitrate of ammonium and 2 parts water. Press it upon the filings and they will be printed on the paper in blue.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Electric Railway Boom.—Electric Light Wires Start a Fire at Headquarters.—Mayor Low of Brooklyn Opposes Underground Lines.—The Bankrupt Telegraph Company.—Activity in the "Ticker" Business.—More Electric Lighting Wanted.—Removal of J. H. Bunnell & Co.—Electricity as a Highway to the Penitentiary.—Leclanche Jars as Jam Pots.

It appears certain that the present year will witness substantial progress in the establishment of electric railways in this vicinity. The suggestion that electricity be given a thorough trial on the elevated railways, has met with the approval of the Manhattan Railway Co.'s managers, and the Van Depoele Electric Manufacturing Co. of Chicago has been added to the list already embraced by the American Electric Railway Co. It is also reported that Magnus Volk, proprietor of the Marine Electric Railway at Brighton, England, has applied for admission into the association. He is very confident that electric power will be successful as applied to our elevated railroad system.

The Daft company is already engaged in preparing the Brooklyn bridge railway for a trial of its electric motors. The experimental trips will be made without interfering with the existing cable arrangements. Electricity will gain some prestige on the bridge railway if not elsewhere, as the cable system has had the reputation of failing several times when it was most urgently needed. While the electric railway is a novelty it will certainly attract a large number of passengers who might otherwise go elsewhere. Its use may therefore be looked for in connection with the vast excursion traffic to the beaches during the summer. A survey has already been completed for an electric railway between Far Rockaway and Rockaway beach. The total length of the road will be a little more than 5 miles. The rails will be laid on an iron superstructure similar to that of the elevated railways in this city. It is expected that the contracts for building the road will be made within a few days, and work commenced immediately afterward, as it is intended to open it for travel on July 4 next. The projectors recently filed articles of incorporation in Albany and Jamaica for the Rockaway Electrical Railroad Co., with a paid up capital of $200,000. It has already been reported that the introduction of electric motors will be opposed by the Brotherhood of Locomotive Engineers, but their advent will doubtless be welcomed by the stationary engineers, At all events the success of the system will depend on its merits, and the suspension of traffic for a few days on the short elevated railways, where other means of transportation exist, would not be a very serious matter to the public.

The high wind which visited this city on the 17th was unusually severe in its effects on the telegraph lines throughout the country. In New York it presented renewed arguments for placing the wires underground. By a cross between an electric light and a city fire alarm wire, a dynamic current was conveyed to Fire Hall, which started a small conflagration and for a moment threatened disaster to the entire apparatus at headquarters. Of course active measures were at once taken to extinguish the flames, which were so immediately successful that the damage was not serious. The insulation on some of the electric light wires must be nearly worthless, and with the prospect in view of being forced to place their wires underground, it can scarcely be expected that their owners will incur any expense in their maintenance which can possibly be postponed.

Brooklyn is the only place in the state outside of this city to which the underground telegraph bill is applicable. Both of these cities have had their borrowing authority cut off by a recent constitutional amendment, and are now confronted with the unusual expense of burying the municipal wires as required by law. Mayor Low in his annual message was very decided in his opinion of the underground bill, as is shown by the following extract:

> The Underground Telegraph law, so called, of last session has been a great embarrassment to the city. Its only known effects thus far, excepting a slight experiment with underground wires by the telephone company in the neighborhood of the City Hall, have been to prevent the city from securing $5,000 worth of telephone service per annum free of cost, and to prevent in a number of instances, the extension of the fire alarm telegraph system. The effect of the law is wholly negative. It does not provide a single positive direction or method as to the accomplishment of the end which it enjoins. I am clearly of the opinion that Brooklyn ought to be exempted from its provisions unless at the ensuing session of the Legislature it can be made a practicable measure.

The receivers of the Bankers and Merchants' Telegraph Co., are still pulling hard against the rapids. They have effected settlements with some of the larger creditors of the company, partly on a basis of 60 cents on the dollar, while others were paid in receiver's certificates having two years to run. The employés are paid in driblets. The Baltimore and Ohio company is continually adding to its working force. The recent acquisition of D. J. Ludwig and some of his assistants from the Commercial News Department of the Western Union company, points to the organization of a similar service by the new company. A system of quotation printers will also be added. Mr. W. F. Coffee is actively engaged in preparations for starting a quotation system using the Woershing printer. The failure of the Gold and Stock Telegraph Co. in its efforts to obtain an injunction against the Commercial Telegram Co., will allow the latter to continue in its vigorous competition for this lucrative branch of the telegraph business. The Gold and Stock company will soon be in the field with an equipment of Scott printers, which it is expected will enable it to keep abreast with the transactions of the stock exchange during the most active market. The new instruments will be operated by dynamic electricity, and the estimated cost of the change is over $100,000. It is believed that this expenditure will however place the company so far in advance of its rivals, that it will be secure in its practical monopoly of the business for many years.

It is reported that the New York Steam Heating Co. has offered the government a rental of $10,000 per year each, for the basements of the Custom House and Post-office buildings in which to locate plants, probably for electric lighting. It offers to light and heat the buildings in addition to the rental. This service now costs the government about $80,000 annually. It is understood that the supervising architect will report unfavorably to the proposition, on the ground that the government is likely to need the space, and also that it would be an improper precedent to allow private parties to obtain such a foothold on the premises named. If this attempt fails it will doubtless be renewed after the coming administration takes charge of affairs. There is a demand for more electric lights down town than the Edison company can furnish, and since the reduction in the price of gas from $2.25 to $1.75 per 1,000 feet, there has been a general complaint that the quality of the gas has so deteriorated that there is really no benefit to the consumer.

J. H. Bunnell & Co. have removed to the south-west corner of Liberty and New Church streets, a few doors east of their old stand No. 112 Liberty street. The new store runs through from Liberty to Cedar street, while half of the frontage on New Church is of glass, making a salesroom exceedingly light and convenient. The location is quite a prominent one, and the change will no doubt prove beneficial to this young and enterprising firm.

Electricity has been recently identified with several incidents, which have brought the participants into the hands of the police. A young man who was discharged from a lumber yard in Brooklyn recently, made his old employers happy for a time, by telephoning orders from different customers for lumber to be delivered at various places. His scheme was discovered, and the boom in the lumber business terminated before he had made any sales.

Just before the holidays John Cunningham and John Burns wearing the uniforms of Western Union messengers, and fortified by a "New Year's greeting" under the guise of poetry, visited various down town merchants and brokers, and collected $820, which it was supposed they were to divide with their comrades. The fraud was discovered and the two bogus messengers were convicted of petit larceny, and sent to the penitentiary for one year.

John H. Davis & Co. called a messenger from the Independent Messenger Co., which does business for the Stock Exchange. The call was answered by W. H. Devlin, who took $1,365 in coupons to the Merchant's Exchange National Bank to be cashed. Contrary to ordinary business usage the coupons were paid in greenbacks instead of a check, and the boy failed to return. A detective was put on his track, and he was finally intercepted at Syracuse on his way to Montreal, and $1,050 recovered, also $266 which he had left with a comrade in this city.

The burglar alarm apparatus of a well-known Paterson manufacturer, living in Broadway, refused to work, and an electrician was sent for. He found that some one had removed the battery from the shelf in the cellar where it had been placed. The cook, being consulted, explained that she had found the jars and washed them out, as the sweetmeats were all spoiled and mouldy. Then she proudly pointed to the missing battery jars, as bright as new dollars, on the kitchen shelf with the fruit jars.

New York, Jan. 25, 1885.

CHICAGO.

How Fires in Theatres are to be Promptly Extinguished.—Tests of Various Insulated Wires.—Who was the Original Inventor of the Storage Battery?—The Chicago Driving Park Not Yet Lighted by Electricity.—Telephone Dividends Payable on Sunday.—The Van Depoele Electric Manufacturing Co.—Electric Light Interests Awaiting Action of the City Council.—Cut-throat Telegraph Rates.

My attention has lately been called to an electrical arrangement for theatres, public halls and the like, where, from the inflammable nature of the scenery and stage appurtenances a conflagration, with all its concomitant horrors, is ever possible. The inventor is a Philadelphia gentleman, whose name figures quite extensively in the patent office reports of the past few years. In the office of the chief of the fire department this gentleman, Mr. W. C. Shafer, has placed a complete working model of a theatre, with a very pretty little stage set, the curtain up and all as if a

play were being enacted before an audience. After a full explanation of the *modus operandi* of the apparatus, he touches a match to a string, which burns, of course. Down drops the curtain by the run, a trap door in the roof opens over the stage, an unexpected deluge of water falls, the auditorium doors fly open, and the audience presumably make their exit before having hardly smelled the smoke of the burning, while, as they emerge, they see in the foreground of the out-door picture the representatives of the fire department at full gallop in response to the thermostat alarm. The whole apparatus is ingenious and quite complete in all its connections and arrangements. In practice the curtain is of asbestos cloth, on a wire netting. By means of a weight of 700 pounds, and a combination of gearing, this is held suspended by a mere string, and when released will drop about 34 feet in six seconds. During the first foot of this descent it rings an alarm bell to the actors, who clear the line of its drop; or, its machinery may be discharged by means of a thermostat, in lieu of the burning string. In case of an accidental release of the curtain a cord at the prompter's side of the stage governs a break, which perfectly controls the falling curtain at any point in its descent. The battery used is normally closed, and a magnet in the circuit notifies the party in charge by ringing a bell through a local circuit when the current of the main battery is weakening, but before this has so far failed as to let go the sustaining magnet. If the combination will work as well in practice as in the model it certainly looks like a valuable adjunct—for very little expense —to the show business.

Insulated wire for underground purposes still holds its own as a topic of interest. Samples are constantly making their appearance here, and hardly a week passes without a test—and these are crucial—in the city electrician's department. Some months since I chronicled a test which was far from satisfactory on a sample of one of these, a much advertised and much endorsed wire, nearly a quarter of a mile long. A second sample of the same wire was recently made and sent here which was even worse than the first, giving less than one-half the insulation resistance. On the other hand a sample of wire 350 feet in length, cased in a copper plated hard rubber tube, was coiled in a large tank of water for several days, and during the last three days of the immersion 8 tests were made at intervals of several hours. These tests invariably showed the same result—3,000 *meghoms to the mile!*

A sample of wire insulated with gum copal dissolved in castor oil, cotton wrapped, showed absolutely no value after a limited immersion. Nor was this the result of a leak from some single point—for when after removal from the tank it was laid upon the floor, the general leak was made apparent whenever a ground connection was made with its damp outer covering at any point. It is but fair, however, to state that the wrapping was poorly done, and the whole sample reminded one of the musical expert's remark on a new song handed him for criticism. "It looks as if somebody had made it himself."

In an article on storage batteries (O. J. L., in *Nature*), in the January number of your journal, Faure is credited with the invention of the storage battery. I had the impression that Gaston Planté was the original inventor, or at least, was before Faure. Faure claimed originality for the invention, and this was controverted in the "Société d'encouragement," in 1881, by Emile Reynier, in favor of Planté. The late Comte du Moncel, at that time in an editorial on the preposterous claim, said: "We would like to know where is the originality in this invention of M. Faure. Does he employ other electrodes than M. Planté? Is the effect produced by electrolysis in his battery different from that produced in the Planté? Is there not always a film of peroxyde of lead formed at the positive electrode? In principle, in materials used, in form, and in results obtained, there is absolutely nothing new in the Faure battery," etc. Still, the old saw, "a lie will travel from Maine to the Rocky Mountains while truth is pulling on his boots," will continue as trite and applicable as ever, while Drawbaughs and Faures cumber the ground. A prominent Chicago inventor's definition of a patent claim comes to mind in such cases. One fellow invents a coffee pot. Another changes the places of the spout and handle, and claims this as a new invention; "because, don't you see, neither the spout nor the handle are on the same side as in the other, and besides, mine was the original invention, anyhow."

How often it is necessary to go abroad for home news. One of your electrical contemporaries in a review of electrical events and progress in 1884, mentions that "at Chicago an installation was made of 330 arc lamps to light up a new driving park," etc. When someone was "making" a dictionary, he submitted a definition to a lexicographer for criticism. "Crab—a fish, of red color, which swims backward." "Correct, except in three particulars. A crab is not a fish, it is not red, and it does not swim backward," was the criticism. Three hundred and thirty lamps were not installed in a new driving park; there was no installation except in an old driving park, which consisted of but 10 arc lights; this plant was only for a special occasion, and remained but four days.

The Chicago Driving Park is to be lighted next year, with 230 Western Electric lamps and 100 Excelsior lamps, which will be inaugurated on June 6th. The machines for this plant are being constructed, and poles will be set as early in the spring as the settling of the ground will permit.

The Wisconsin Telephone company paid a quarterly dividend last week of 2 per cent., making their tenth. The Chicago company has also divided with the holders, and the Central Union has declared a quarterly 1½ per cent., payable on the 25th. Let's see; what day of the week did you say that would be?

The Van Depoele company has reorganized and is now the Van Depoele Electric Manufacturing Co. I was at their shop a day or two since, and while they complain like all the companies of hard times, they are as busy as nailers on lamps and motors. One of these of 50-h. p., is being built for railway service, and as this company is one of the many in "The American Electric Railway Co." consolidation, it will probably make its *debut* among those to be tried on the Second avenue elevated road in your city. Mr. Van Depoele has introduced in this, as he believes, some new and peculiar combinations which will give important results. I am not at liberty to mention details, but may say in general that, judging from results obtained in the performance of a 20-h. p. motor, in running the machinery and elevator of the shop, he has good foundation for his belief.

The electric light companies as a rule are comparatively at a standstill for a time. The petition of sundry citizens to the city council, asking permission to hang outside lights has not yet culminated in anything save delay, and of course it is impossible to foretell what the outcome will be. I honestly think, however, that all will yet be satisfactorily arranged, and that work will soon resume its former activity.

The B. & O. Telegraph Co.'s cut in rates was rather a surprise, but the business of the other companies seems little affected by it, to judge from the standpoint of an outsider. It will undoubtedly increase the amount in gross of telegrams sent, for the rates are now so low that one can often better afford to telegraph than wait for the fastest mail.

CHICAGO, Jan. 15, 1885.

PHILADELPHIA.

An Era of Litigation.—The Telegraph Companies object to the Pole License Fee.—The Referee Decides that the Fees are Unreasonable.—Judge Biddle's Decision in the Local Electric Light Suit.—Plans of the American Telegraph and Telephone Co.

THE Referee appointed by the Court in the suits of the city against the Western Union and Mutual Union Telegraph companies and the Bell Telephone Co. has filed his report, in which he finds for the defendants in every case.

The ordinance of 1881 provides that "no pole shall be erected without the license of the Superintendent of the Police and Fire Alarm Telegraph shall have been obtained therefor, and for every license so granted shall be paid to the city treasurer, for the use of the city, the sum of $5 per pole." Further, it says that application shall be made for continuing the license for the ensuing year, and the charge for such license shall be $1 for each pole. The ordinance of 1883 says: "On all conductors or wires suspended above ground, except such as are used or owned by the city of Philadelphia, an annual payment of $2.50 per mile, or part thereof, in length of wires or conductors, shall be paid for each and every wire or conductor used or to be used for telegraphic, telephonic, or other purposes." "Failure to make payment as required thereby shall subject the offender to the penalty of $50 per month for each and every day thereafter until payment is made."

The actions were brought to recover the license fees and a penalty said to have been incurred by the Bell Telephone Co.

The defendants filed answer, claiming that the municipality had no power to enforce ordinances; that the fees are unreasonable and amount to a revenue; that they exceed the rate of taxation on other property, and operate in restraint to trade, and that the companies had paid state tax on the poles and wires.

The fees claimed amount to $6,885. The Referee's report says: "If the exaction of a license in any case is simply a means, in good faith, of enforcing reasonable police regulations, then such exaction is a *legitimate* use of the power to regulate. If it is an attempt to tax, then it is an abuse.

"I conclude, therefore, that the city has a right to exact reasonable license fees for the erection and maintenance of poles and wires, and the question then is whether the fees sought to be charged by the ordinances of 1881 and 1883 are reasonable, which brings us to the third question discussed before me.

"I am of the opinion that the license fees required by these ordinances are not reasonable, and are, therefore, not within the proper powers of the police regulation possessed by the city. They are in effect an attempt to impose a tax, which the city has no right to do.

"That the fees are unreasonable seems to me to be apparent from the undisputed facts of the case. The total cost of maintaining the whole system of police and fire alarm telegraph is about $25,000. Of this, only 10 per cent., or $25,000 at the most, is chargeable to the expense of supervising the erection and maintenance of poles and wires by telegraph and telephone companies. License fees which would aggregate only $2,500, or perhaps $3,500, would be a reasonable exercise of the power of regulation. License fees of which the total amounts to 50 per cent. of the whole expenses of carrying on the depart-

Digitized by Google

ment are, to my mind, in the nature of tax. This view seems to be strengthened by comparing the amount paid with the value of the property. The cost of erecting poles and wires in the city is, according to the evidence, in the neighborhood of $500 per mile. This is estimating 40 poles per mile. The tax in such case would be something over $40; in other words, nearly 10 per cent. of the value of the property. If it be said that the value of the poles and wires is no criterion as to the value of the property, the property being really the franchise to erect poles and stretch wires, the answer is that the corporations already pay tax on their capital stock, and that there would seem to be no authority on the part of the City of Philadelphia to do something which would practically amount to levying a tax upon the corporate franchise.

"For this reason, therefore, namely, because the license fees exacted are unreasonable as fees, and because they operate in substance as a tax, I am of opinion that the ordinance cannot be enforced, and that the finding in each of these cases should be for the defendants, and I accordingly so find."

Judge Biddle recently delivered an important decision sustaining a demurrer filed by the Underground Electric Light and Power Co., in the suit brought against that corporation by the electric light company which operates the Brush system. The latter company was incorporated under the general incorporation law of 1874, under the 34th section of which they claimed to have the exclusive right to supply electric light to this city until they had for five years declared dividends equal to 8 per cent on their capital stock. They asked that the Underground company should be enjoined from violating their exclusive right, such profits not having as yet been realized. Judge Biddle first remarks that, before a claim of this magnitude can be allowed, a court of equity must be entirely satisfied that it was the clear intent and meaning of the law, under which the right is claimed, and that all the provisions of the law have been strictly complied with, and then discusses the several provisions of the act and the best settled rules of statutory interpretation. He then says: "The complainants having failed to satisfy us that they have received the lawful consent of the authorities to erect their works in the city, the demurrer in this case is sustained.

The gentlemen interested in the American Telegraph and Telephone Co. have received word from Harrisburg that the charter they applied for some time ago had been duly granted. This company proposes to run lines from Philadelphia to Easton and Pittsburg, and ultimately to extend its operations to all the principal cities and towns of the state. The incorporators are Messrs. J. E. Kingsley, Samuel B. Huey, Josiah R. Adams and F. E. Buchler, of Philadelphia, and Thomas B. Doolittle, of Boston. This company will use the Bell system.

PHILADELPHIA, Jan. 16, 1885.

BOSTON.

Mysterious Manifestations of Massachusetts Mayors' Master Minds.—What Boston Deems a Big Fire Turnout.—Patent Litigation Between Electric Light Companies.—The Western Union Puts 30 Wires Underground.—Organization of the Boston Telegraphers.—The Electric Light Consolidation Still in Abeyance.—An Electric Ship's Log Register.—Calling a Cab and Catching a "Cop."—Improvements in the Fire Alarm System.—The Electrical Exhibition and its Attractions.—A New Blake Transmitter.—The B. & O. Telegraph Co. Loses its Telephone Service at New Bedford.

IT has been interesting to observe the workings of the various great minds inaugurated as mayors of the cities in this vicinity, so far as they grasp the electrical problems before them. The mayor of Boston speaks highly of the electric light, and figures out economy in the present system of lighting. The mayor of Lowell recommends that some of the electric lights be discontinued; and in consequence of his remarks that the police telegraph, which has been in use in that city, was unnecessary, impracticable and unauthorized, it has been taken out. The mayor of Newton recommends that the school houses be provided with private fire alarm signal boxes. At Haverhill his honor suggests the use of a 5-circuit repeater in connection with the fire alarm. The new mayor of Worcester advises putting in more electric lights. In Springfield the newly-elected recommends the adoption of a police and telephone system.

An alarm from box 746, December 29, brought to Jordan & Marsh's extensive dry goods house 7 steamers, 3 ladder trucks, 2 chemicals, the water tower, aerial ladder and Hayes truck, and, in the words of one of the engineers, "it was the best turnout the department has made in 20 years, every piece of apparatus being promptly on hand." No. 746 is one of the 14 special boxes located in hospitals, theatres, public buildings and large dry goods stores, and each one calls for a large number of pieces of apparatus on the first alarm. An immense crowd of people swarmed to the scene, but fortunately nothing was burned of any account. Fifty dollars will cover the fire damage, although the smoke may have caused more.

The United States Electric Light Co. have commenced suit against the Thomson-Houston Electric Light Co., of Connecticut, having its factory at Lynn, Mass.; the American Electric Illuminating Co., and the Merchants' Electric Light & Power Co., of this city, for the alleged infringement of an important patent connected with the electric light. The New England-Weston Electric Light Co. is a party in the suits against the last two named companies. A permanent injunction is asked for. The infringement alleged is on E. Weston's patent—234,443, November 16, 1880—on a ventilated armature for dynamo machines. The Thomson-Houston company defends the suits.

On January 1st the Western Union switched 30 of their overhead wires into their new underground system, through to Friend street, and have them now all in use. They work very well. The unsightly poles, over which there has been so much agitation, will now come down and be made useful in some other place or capacity.

On the afternoon of January 4th the telegraphers held a meeting at Young's Hotel. Officers were elected and a complete organization was perfected, but the names are not made public. The name is "Boston Council, Telegraphers' Protective Union," with an enrolled membership of 60 members, from all the telegraph companies of the city.

The consolidation of the local electric light companies does not as yet come off. Committees have been appointed from two of them to consult, but at last accounts they had not met very unanimously. There are always to be found people who are willing to consolidate and unite to divide the profits with those stronger and more prosperous than themselves.

A new and simple electric ship's log has been on exhibition in Gloucester, the invention of two young men of that place. The object of the invention is to register, by means of an electric current on board of sail or steam vessels, the number of miles traversed through the water. The flange spindle has a projected point, and at each revolution of the propeller the projecting point touches the spring on the diaphragm, presses it against a cable wire and closes the circuit. On board the ship is placed a register, and when a mile has been made the figure 1 appears on its face. With the use of this log the register can be taken without raising the log from the water.

The necessity of making proper connections was aptly illustrated one evening recently as a gentleman, late in the evening, sauntered into a district box cubby to have a herdic called to take him to the railroad station. The boy in charge gave the wrong call, and summoned the police. Meanwhile the gentleman, seizing his gripsack, sauntered out. In came the "cop" with a boy. The "district boxoneer" told the boy he would find the passenger down the sidewalk, describing him, etc. Soon the passenger, struggling in the hands of the "bobbie," returns, the latter inquiring what offense the former had committed. Mutual and triple explanations ensue. By this time it's too late for the train, and the passenger retires to a hotel to dis-*cuss* the district system.

The fire alarm office at the City Hall has been improved in many ways within a few weeks. A number of new receiving and transmitting instruments have been placed in position. To provide for the gradual increase of the system, as more territory is covered by the fire department, arrangements have been made so that with a few connections alarms can be received from 36 circuits, 21 only now being in use. There are now 365 fire alarm boxes and about 300 miles of wire. As a precaution, in case of the destruction of the fire alarm office by fire, the superintendent has established in various fire department houses a number of batteries, by which, in a very short time, a complete fire alarm system would be in operation throughout the city.

The Electrical Exhibition is still offered to the public as a means of entertainment and amusement. It is a very pleasant place to pass an evening. The exhibits are mainly of a kind to mildly instruct and please the popular mind. As a technical electrical exhibition it has no claim, but there is variety enough in the exhibits to draw that floating portion of the people who want to go somewhere. The daily papers have been kind in their notices, and each new arrival has been duly mentioned. Thos. A. Edison has been a frequent visitor. As he is a prominent exhibitor, his anticipated presence has always been announced, and he has in fact been made an attraction. To his and Mr. Ezra T. Gilliland's efforts what success the exhibition has had is largely due. Edison has a pretty show of incandescent lamps, sections of his underground wires, quadruplex and telegraph apparatus. The phonograph has been an attraction. The Oram telephone time repeater is in charge of the *Electrical Review* company. The Weston company show very handsome clusters of lamps. "Easy Lessons in Electricity" is being printed on a press run from a Weston dynamo; Kettell's clock regulating system is shown. The blind carver works behind a bench; what circuit he is on does not appear. Devices for utilizing wave power are explained by a young woman; this is *not* the Vienna or any other hair wave. Gear cutting machines and castings abound. Blodgett Bros. exhibit as a part of their admirable show the engine and dynamo recovered from the wreck of the "City of Columbus." The Jerome Redding company have a good exhibit; their watchman's register, with type-writer card, is something new. Washburn & Moen have an exhibition of wire of all kinds. At this "electrical" exhibition one can buy all kinds of ivory articles; Waterbury watches; a convenient kerosene fixture; rubber stamps, of which the rubber is vulcanized, heated, etc., by "electric" heat. The attendance has been small, and not much interest has been shown by the exhibitors. In most cases

Digitized by Google

no one is in attendance to explain the exhibits, and of those who *are* on hand, unless they have something to sell, they gaze at one with a stony, glassy stare.

Mr. Francis Blake, as the journals have announced, has invented what he calls a "new Blake transmitter." He has made a great many experiments with it, in various forms, and yet no one knows what it is, excepting his patent solicitor. Mr. Blake has a laboratory and workshop at his residence in Weston, Massachusetts, and makes all of his models and experiments with his own hands. I had the pleasure of listening to the new transmitter, Mr. Blake speaking from Weston to Boston, a distance of about 15 miles. The transmission was loud and the articulation remarkably clear.

The Southern Massachusetts Telephone Co., on the 15th inst., endeavored to remove their instruments from the Baltimore and Ohio Telegraph office at New Bedford, and were resisted, as the service had been paid for in advance. The telephone company has ordered its operators not to respond to the calls of the B. & O. Telegraph Co. A war appears to be in prospect.

BOSTON, Jan. 17, 1885.

WASHINGTON.

Mr. Money's Postal Telegraph Bill Goes Over Four Weeks.—A Grand Electric Lighting Scheme Probably Killed.—Installation of Incandescent Lamps by the U. S. Company.—Extension of Electric Street Lighting.—Successful Working of the Various Subterranean Wires.—An Experimental Exhibition of a New Electric Lamp.—Weston Lamps for the Washington Monument.

MR. MONEY, Chairman of the House Committee on Post-offices and Post-roads, had indulged in a faint hope that his committee would be reached Jan. 19 under the rule permitting suspension of the rules for action upon the Postal Telegraph bill, but the day was spent on obstructions thrown in the way of the passage of the bill to place Gen. Grant on the retired list, and with the day went Mr. Money's chances for the next four weeks, and probably for the session, as the appropriation bills will probably interfere with another effort as late as the 16th of February. It is not likely that the bill would have received the necessary two-thirds vote, but it would have been interesting to have seen how the House stood upon the question. With this goes almost the possibility of legislation on the telegraph by this Congress, and its prospects for the next are not much brighter unless it is made an Administration measure, which is in no wise likely.

In April last Mr. Cosgrove introduced in the House a bill "To authorize the lighting of the navigable waters of the U. S. with electricity." The bill authorized O. W. Childs and his associates "to acquire, hold and own" suitable stations and to erect and use suitable appliances therefor, with the right to enter into contract with and receive pay from those who desire the use or who may be benefited by the system of light adopted. The said Childs and associates were to be permitted to establish such system of transmitting intelligence as they might deem proper in connection with said system of electric lighting. The bill went to the Committee on Commerce and comes back somewhat circumscribed; the substitute simply authorizing the construction at their own expense of the necessary building rafts or other structures for the purpose of experimenting in electric lighting, providing such structures shall not interfere with navigation, and after plans, specifications and drawings have been submitted to and approved by the Secretary of War. This bill will probably go, with several thousand others, into the waste basket, March 4th.

The incandescent lamps for the branch of the government printing office located in the sub-basement of the Treasury building, by the United States Electric Light Co., were lighted on Wednesday last and prove highly satisfactory. The location is such that the ventilation is very imperfect, and the substitution of electricity for gas is warmly welcomed by the employés. The same company will in a few days place a number of the 125 c. p. lamps of the Weston patent on the upper floors of the Treasury building. It is proposed to place 200 incandescent lamps of this company in the Interior Department, as soon as the wires can be run.

The street lighting by the United States company on F street has proved so satisfactory that, encouraged by the business men on 9th street, they have applied for and been granted permission to light that street from F street to Pennsylvania avenue, the authorities paying an amount equal to the contract price for gas, and the merchants benefited paying the difference. Application has been made by the United States and the Brush-Swan companies to light Pennsylvania avenue on the same terms, but as yet neither have received the desired permission. The rivalry between 7th and 9th streets is so great that the former will soon come under the electric system.

The telephone company has recently laid a 100 wire cable from its exchange, New York avenue, between 14th and 15th streets, to the corner of 5th and D streets, a distance of about a mile and a quarter, and the wires are working well. With enough electric light, telegraph, fire alarm and telephone wires underground to make a thorough test, and all working satisfactorily, the district commissioners feel strengthened in their efforts to drive out the overhead wires.

The revived telegraph lines are not likely to crush out their older rivals soon. I hear that the Bankers and Merchants' company have not paid their employés for several months, and that they are getting quite despondent. Manager Cox and his associates have been untiring in their efforts to build up the business, and their zeal deserves a better reward.

Mr. J. Von Gestel has been exhibiting a new electric lamp of his invention in the basement of the Capitol for a few days past. His light is produced by a very small carbon in contact with a copper rod—a semi-arc light—with a short bar of compressed and baked magnesia resting above the point of contact. This, he claims, absorbs the heat and prevents the consumption of the carbon, while the magnesia becomes incandescent, throwing out a brilliant light. His experimental lamp is crudely made and not well balanced in the several parts of its mechanism, and has not yet reached the maximum claimed for it, but gives good promise of doing so. Further tests are to be made.

The Edison people have been invited to substitute their lamps for gas in two of the panels over the Senate chamber, as a test of the two modes of lighting. If the test is satisfactory, they will substitute the incandescent light for gas in all the panels, and probably in the business offices of the Senate before the meeting of Congress in December. The long night sessions incident to the last days of a Congress will afford an excellent opportunity for testing, side by side, the two modes of lighting. It is a question of convenience rather than of economy, and the lamps stand a good chance to win.

The following statement which I noticed in a recent New York daily, is not in accordance with the facts so far as this city is concerned.

Thomas A. Edison, inventor.—A dark day, yes, but all those clouds have a silver lining for me. How is that? Well you see on days like this the out-turn of light in the down-town central station is about doubled and our receipts are correspondingly increased. Busy? Never more so. I have got out a new batch of telephone improvements. They think well of them in Boston. You have heard I suppose that the light company has just signed a contract with Colonel Casey, the chief engineer of the Washington Monument, to light the interior with 125 lamps. That puts the electric light 550 feet in the air, considerably higher than we ever expected to get when we hung the first lamp on a telegraph pole in Menlo Park a few years back.

On January 24 at 12 o'clock the bids for lighting the Washington monument by electricity were opened, and the contract awarded to the United States Electric Lighting Co. of this city for $1,972, being $28 below the Brush-Swan, and $628 less than the Edison, offers. The specification calls for an incandescent dynamo, of not less than 150 lamp capacity, 75 lamps and appurtenances, to be ready for service on Feb. 21, when the dedication is to take place.

The sleet storm of January 23d prostrated telegraph and telephone wires in every direction. The occasion was taken advantage of by President Waring of the Standard Underground Cable Co., who availed himself of nature's protest against overhead wires, to advance the interests of his cables in government circles on the following day.

WASHINGTON, D. C., Jan. 26, 1885.

NEW ORLEANS.

Incomplete State of Electric Light Plants.—The Edison Company's Installation a Great Success.—What the Other Companies are Doing.—Improvements in the New Orleans Telephone Service.—The Louisiana Time Telegraph Co.—The National Improved Telephone Co.—The Coming Electric Railway.

NOTWITHSTANDING all the efforts in that direction, the several plants for lighting the exposition grounds and buildings are not entirely in readiness as yet. The Edison company is in advance of the others, inasmuch as its plant in the main building was completed some time since, and has been running without interruption. This, they claim, is the largest isolated plant that has ever been erected—capacity over 5,000 lamps. From its unique design it is called the "Fort Edison Battery." Six engines are placed as the spokes of a wheel, and the 12 dynamos (400 ampère machines) driven by them, surround them in a circle. Two thousand lamps are placed in Music Hall and its approaches. Conspicuous in the former are the 5 beautiful clusters of 70 lamps each, suspended along the centre of the dome. The various offices in the building and its entrances require 1,000 more, and the art gallery, 2,000 feet away, is wired for another thousand. Besides these, the Furniture Pavilion of the Grand Rapids company will use a considerable number. In the government building a 1,500-light plant is being put in, the wires having already been distributed to the offices located therein.

The Louisiana Electric Light and Power Co., are putting in 35 30-light Excelsior machines, of which a number have been

Digitized by Google

running for a month or more. Their contract calls for 800 standard arc lamps for the interior of the main building, which they say is the largest of like character ever made. They will also furnish lamps to any exhibitors who may need them. A 36,000 candle-lamp, will probably be placed in each of the 5 entrances to this building.

The Jenney Co., have 5 Star towers within the grounds, upon each of which are 10 lamps.

The Thomson-Houston Co., illuminate Horticultural Hall.

The government building (excepting the offices lighted by the Edison Co.) is contracted for by the South-western Brush Co., but has not yet been thrown open to the public at night.

Last spring The Great Southern Telephone Co., succeeded the Louisiana Bell Co., to the business of this city, and since then a great change has been made in the systems. All wires were transferred from house-tops to poles, a new and more suitable exchange building was moved into, and affairs generally greatly improved. Lately a new multiple board of the Western Electric Co. has been put in, the connections being changed to it in 45 minutes. Over 1200 subscribers are on the books and more coming in. Connecting lines are in operation along the river as far as Port Allen—140 miles. A line to Baton Rouge is now being built of No. 14 hard-drawn copper wire from the Ansonia Co. Other lines radiating in nearly all directions from the city, are either built or under way, upon several of which 14 copper wire is used, when these are all completed, this section of the country will certainly enjoy unsurpassed telephonic facilities. In the main building of the exposition, a branch exchange has been established, which can accommodate 300 subscribers. This is connected by trunk lines with the city exchange. The Great Southern, does not appear to fear the coming of rival companies into the field, of which so far it has enjoyed the monopoly. Its general office has been transferred from Nashville to this city.

The Louisiana Time Telegraph Co. is trying to get a foothold among our people, and perhaps in *time* it will succeed, at any rate it will have a good many subscribers for a few months, as the company will put in clocks, *gratis*, for that period; hoping that at the end of that time, they will make a ten strike and wring out the necessary "shekels" for a continuance of the service. Some 200 clocks are placed on the 4 circuits already established.

The National Improved Telephone Co., recently organized and chartered under the laws of this state, propose to compete with the Great Southern for the business of this city. They have licensed the Crescent City Co, who have 1,000 poles on the way, and who are going right to work. They use instruments patented by Chas. A. Randall and T. J. Perrin, and for a switch board use the Perrin multiple exchange system, also the McTighe receiver. This company has an exchange in the centre of main building, connecting the various exposition offices upon the grounds with each other and with those in the city.

An electric railway will soon be ready upon the grounds. The track is completed, and the Daft motor is expected daily.

NEW ORLEANS, Jan. 13, 1885.

ELECTRICAL NEWS AND NOTES.

THE DECISION IN THE CANADIAN TELEPHONE CASE.[1]

On January 24, 1885, the Hon. J. H. Pope, Minister of Agriculture and Commissioner of Patents, rendered a decision in the Toronto Telephone Manufacturing Company vs. The Bell Telephone Company of Canada. This is a case of dispute raised against the existence of Patent No. 7,789, granted the 22d of August, 1877, to Alexander Graham Bell, and now owned by the Bell Telephone Company of Canada, for alleged forfeiture on the ground of non-manufacturing and of importing, in the terms of Section 28 of "The Patent Act of 1872." Messrs. Roaf, McLean, White and Johnson were counsel for the disputants, and Messrs. Hector Cameron, Dalton McCarthy, Dr. McMichael, Hon. Wm. Macdougall, Z. A. Lash and S. G. Wood for the respondents. The petition addressed to the Minister of Agriculture (bearing date 2d September, 1884) by the disputants, represented that patent No. 7,789 is null and void, and should be so declared, for non-compliance with the provisions of the 28th section of the Patent Act of 1872, requiring manufacturing within two years and forbidding importation after twelve months.

THE MINISTER'S DECISION.

The following is the full text of the decision:—This case is the second which has come before this tribunal. It happens that both cases concern interests of vast magnitude, a circumstance which contributed to enhance the sense of the heavy responsibility imposed by the law on me as the Minister of Agriculture, or on my Deputy, in this respect. The first case—*Barter* vs. *Smith*—was tried before Mr. Tache in November, 1876, and his judgment was rendered in February, 1877. I have to refer to that judgment, because it has been made the basis of argument by the learned counsel on both sides in this case, because it constitutes the declaratory law of the country on points raised by the application of the 28th section of the Patent Act of 1872, being in matter of doctrine and of legal interpretation unquestionably correct; and endorsed, as remarked by Mr. Cameron, by the highest judicial authorities, namely, the Court of Appeals of Ontario, the Supreme Court, and, in relation to this present case, by Mr. Justice Osler in his judgment rejecting an application for a writ of prohibition. This tribunal is, therefore, bound to attach great weight to the doctrine and rules of interpretation laid down in that judgment of the Deputy Minister, which judgment embodies the jurisprudence adopted in Canada, when dealing with that section of the Patent Act.

The feature of Patent No. 7,789, granted for what is known under the name of "Bell's system of telephony," is peculiar in so far as it consists both of a process of art and of a portion of the machinery necessary to carry the art into practice. The two elements are inseparable; the electric circuit and the two instruments are the means of giving a practical and tangible shape to the "Bell's system of telephony." Moreover, the instruments, described in the specification and illustrated in the drawings of the patent, are the mechanical contrivances which distinguish this invention from other methods of getting at a similar result. All the elements of which these instruments are composed are of the public domain, and public are also the means of erecting an electric circuit, therefore, the patent is a patent for a new and useful combination of old elements, to obtain an object known beforehand. The combination is the invention, and consequently the subject matter of the patent and mechanism of which it is constituted are new articles of manufacture. The doctrine, universally admitted, of the patentability of a variety of combinations of the same elements for the same object, has been clearly laid down by the Supreme Court in *Smith* vs. *Goldie*. What is patentable is the subject of a privilege, and, in Canada, submitted to the conditions of section 28 of the Patent Act. This patent, like every other patent granted, is, therefore, under the obligations exacted from all patentees by section 28 of the Patent Act of 1872, and subject to the adjudication of this tribunal, should disputes arise as to whether it has or has not become null and void under the provisions of this section. The patent was granted on the 22d of August, 1877, to Mr. Alexander Graham Bell and is now, through a series of assignments, the property of "The Bell Telephone Company of Canada," the respondents in this case. It must be remarked that it matters not who the owners are for the time being, or were at any time; it is the patent which stands before me, as the Minister of Agriculture, to be adjudicated on, not the owners. The patent does so stand with the uninterrupted privileges as well as with the uninterrupted obligations attached to it. This tribunal has not to investigate the *locus standi* of disputants nor of respondents, nor in relation to companies, to inquire whether they are legally incorporated or not; such questions are not within its jurisdiction, and, besides, are quite indifferent to the issue in such cases. When this tribunal is made aware that disputes are raised, in accordance with the provisions of the 28th section, by some person who undertakes to prove his allegations, it immediately becomes the duty of the judges of such disputes to investigate the matter.

In the interest of public rights, if the policy of the law has not been carried out, or in the interest of patent rights if the obligations have been fulfilled, I, as Minister of Agriculture, have not to undertake to initiate cases of disputes, but I must take notice of all cases brought before me in a formal way. The first allegations of the petitioners in this case are that illegal importations have been made of the patented articles, after twelve months from the date of the patent, specifically in the latter days of August, 1878, in January, 1879, and during the years 1880 and 1881. The facts of the first alleged act of illegal importation are as follows:—During the first year of the existence of the patent, the patentee or his representatives in Canada had contracted with Mr. Charles Williams of Boston, in the United States, for one thousand telephones to be delivered within the twelve months allowed by law for importing the invention. At the expiration of the twelve months Mr. Williams had not been able to complete his contract, more than half of the number contracted for having not been furnished. Under the misapprehension, created by the date of the registering of the patent (24th August) that twelve months would only expire with the 24th day of August, 1878, Mr. Williams did forward from Boston, on the 23d of the same month, a lot of seventy-five telephones, which in the ordinary course of transit, should have entered Canada on the 24th, but which, owing to some mishap, did actually pass the frontier only a few days after. The circumstances of these facts show that there was no intention to break through the law, and that the importation was not considerable; therefore this case of importation in the latter part of the month of August, 1878, cannot entail the voidance of the patent.

At the same time that no stress is put upon these facts,

1. We are under obligations to Henry Grist, Esq., Solicitor of Patents, of Ottawa, Ont., for his courtesy in forwarding an early official copy of the proceedings and the decision in this important case.

it is nevertheless an occasion to warn patentees in general against the danger of running so close to the expiry of the twelve months as to incur the risk of coming even a day too late with their last importation. This tribunal is a paternal tribunal, the judges of which are the natural protectors of patentees' rights, and, as such, bound to give to the facts the most liberal construction consistent with a compliance with the spirit of the law; but the patentees are the first guardians of their own interests, and should not put their property in jeopardy by placing these judges in the position of being obliged to overstretch leniency in order to save their patents. During the first year of the existence of the patent, then, the patentee, or his legal representatives, imported, or caused to be imported, about five hundred instruments ready for use, as they had a right to do; a few days after the expiration of the twelve months they also imported, or caused to be imported, seventy-five complete instruments, which latter importation being inconsiderable, and apparently done in good faith, and not with any intention to evade the law, is declared not to have forfeited the patent. There remains now to examine what was done after that time. It is desirable, first, to enter into a cursory examination of the instruments patented as new articles of manufacture. It will, however, be sufficient to investigate the elements of one of these two instruments, the one commonly called the "Hand Telephone," represented in figure 6 of the drawings of the patent. It consists :—1st. Of a casing with a side cover, the whole being at the same time a handle, with a flat ring piece fixed to it, called disc in the trade, and a perforated cup-like screwed top; the whole and the four distinct parts of which are of a form special to this new article of manufacture; this handle casing may be made of any suitable materials, but as a matter of fact is in this case made of hard rubber. 2d. Of four bars of magnetized steel, bound together by screws and nuts. 3d. Of two soft iron pieces, called drop forgings. 4th. Of a bobbin, on which silk-covered, small copper wires are rolled around. 5th. Of wire posts, also called screw cups, and a regulating screw. 6th. Of a metallic vibrating plate or diaphragm, sometimes called disc, as a matter of fact cut out and otherwise worked from what are commonly called japanned or ferrotype plates. 7th. Of a few other insignificant articles of construction. It will expedite matters to consider, together, the two questions raised in the dispute of illegal importation and of non-manufacture, for in the measure that illegal importation goes on, in that measure the industry and the labor of the country are deprived of the benefit of manufacturing. Therefore, we have to examine what, in these instruments, is raw material which does not fall under the application of the 28th section, and what are industry and labor, because it is clear that if the aggregate amount of industry and labor entering into the making of such instruments was mere trifling, unless a criminal intention of totally disregarding the law was shown, which is not the case here, it would not be a liberal nor a reasonable interpretation of the spirit of the law to destroy the patent on account of its importation or non-manufacture. If it were, for instance, amounting in all to a value of ten dollars a year, as the learned counsel, Mr. Macdougall, has it, with the Latin maxim—*de minimis non curat lex*—or even if it were ten times as much as that for every year. As already said, it will suffice to confine our study of the case to the examination of one of the two instruments patented—the "Hand Telephone." The raw materials of this instrument comprise steel in bars, soft iron, wood and vulcanized rubber, to which must be added, as common articles of commerce, silk-covered wires, japanned plates or sheets of ferrotype, as some call them, screws, nuts, and maybe wire posts. The value of each hand telephone complete is about $2.00; the value of the raw materials, including common articles of commerce, entering in each instrument, may be said with certainty not to reach the aggregate of $0.90. Therefore the industry and labor put upon each of these instruments may be set down at about $1.10. One would be inclined to take a much more exalted idea of the value of the labor put upon the two instruments patented, from the statement made by Mr. Sise, the general manager of the Bell Telephone Company of Canada, that their telephone factory at Montreal, established in 1882, has $50,000 capital invested in it, and that the pay-roll of that factory amounts to $30,000 a year wages; notwithstanding that the rubber handles of the hand telephone are not yet manufactured in Canada, as we have it from Mr. Sise, who says that they cannot get them made in Canada, having again vainly tried to do so a week before he gave his evidence in this case, which, of course, can only mean that the Bell Telephone Company have not procured for themselves the moulds to manufacture those rubber handles. Although Mr. Sise does not discriminate the work done at their Montreal factory, it is clear that such an amount of yearly wages cannot be exclusively devoted to the making of the two instruments patented in Patent No. 7,789; but the statement, with all its surroundings, proves that the manufacture of the two instruments is not an insignificant trifle, but is, on the contrary, an advantage worth being looked after. There are many thousands of them now in use in Canada, and there were, at least, several thousands when the Montreal factory was started. The question comes then: Has the patentee or his legal representatives imported or caused to be imported, after twelve months of the existence of their patent, the new article of manufacture patented? There cannot be a shadow of doubt that they have so imported or caused to be imported the articles, manufactured in parts, to be simply put together at an amount of labor, at times paid $0.30, at other times $0.27, in Canada. It is, in fact, virtually admitted by them, when pleading that putting together or "assembling" the parts ready made, is construction and manufacture, in the meaning of the law. It is equally evident that, during the same period, that is coming to the year 1882, they have failed to manufacture to the extent that they have imported, and that, from the year 1882 to the date of hearing the evidence of Mr. Sise, the 3d of December, 1884, they had been importing the rubber handles in a manufactured state. The intention, although not malicious, to evade the law, is nevertheless manifest. During that considerable time of the existence of the patent (to 1882) the same foreign manufacturer, Mr. Williams, with whom the patent owners had contracted for one thousand telephones to be delivered during the first twelve months of the life of the patent, and who furnished only about five hundred during that period of time, did continue to send them to Canada for years to supply an ever increasing demand. But to evade the law and give a color to the importation, instead of sending these instruments consigned to the patentee's representatives, he sent them, in pieces to be put together in Canada, to some one through whose intermediary the patentee's representatives received them when "assembled." All this is proved in the clearest manner by Customs papers, by accounts furnished, by declarations from one of the Cowherds, from Mr. Foster, and by correspondence on the subject. We have it from Mr. Sise himself, with some reticence, but also with some details. He explains the reason why this importation and this non-manufacture were resorted to. "Mr. Charles Williams, one of the owners of the patent," says Mr. Sise, "was and is the only manufacturer of Bell telephones in the United States; he is the only man who is licensed by the Bell Telephone Company to manufacture telephones; he is the only manufacturer to-day that I have any knowledge of ... Mr. Charles Williams was the only man who had that knowledge of it, and who had the control of Cowherd's shop....I think we paid Williams, and I think he was the man who employed Cowherd....Mr. Williams having arranged with Mr. Cowherd to manufacture in Canada, Mr. Cowherd had a number of machines on hand (at the time of Cowherd's death), and Mr. Foster continued the manufacture, and my impression is that he continued to contract with Mr. Foster until we got our shop in such shape that we could make ourselves....There was no time or period when we were not supplied with telephones for the public, either from Cowherd, Mr. Foster or our own manufacture. They were continuously manufactured, inasmuch as they were ready for the public always when they came for them." So far as the law requires a prompt introduction in Canada of a patentee's invention, the patentees have observed the law, as Mr. Sise remarks; but the protective policy of the Patent Act, they have, in intention and effect disregarded and defeated to a very large amount the industrial manufacturing value of the patented article. In support of the pleading that the importation of an instrument in parts is no importation, Mr. Wood, on behalf of the respondents, quoted a recent ruling of the English courts (*Townsend* vs. *Hawthorne*), in which case it was decided that the importation of the materials of a composition of matter was no infringement of the patent; "and," says the learned counsel with reason so far, "what is no matter of infringement cannot be a matter for illegal importation." So far so good; but the conclusion, which is correct in the abstract fails in the concrete, as applied to the present case. The materials of the composition are raw materials unworked, such as would be, in the present case, steel in bars, iron as a commercial article of trade, rubber, and even silk-covered wires; but the moment these are worked into shape and form, to constitute a Bell telephone, they cease to be raw materials and become a manufactured article. Mr. Tache, in his judgment, has anticipated the ruling of the English courts, in the very species of case cited by Mr. Wood. "It is not difficult, says Mr. Tache, to imagine a case in which the importation of all and every one of the component parts of an invention, to be simply put together in Canada, would not be an importation in the meaning of section 28 of the Patent Act ....for example, the case of a patent granted for a composition of matter." It is immediately after this that Mr. Tache adds, referring to such cases: "every one of which must stand on its own merits." The other and last allegation of the disputants is that the patentees have refused to sell their invention after two years of the existence of their patent, namely, to the inhabitants of Port Perry in 1882, to Messrs Lohnes & McKenzie in 1884, to others, and generally refused to sell in order to monopolize the control of the telephonic operations throughout Canada, and derive from their invention more than they were entitled to for the use thereof. A question has been raised on the meaning of the words sale and license as applied to patents. One of the learned counsel was under a misapprehension about the signification of the words used by Mr. Tache in his decision :—"license the right of using on reasonable terms." In this sentence the

Digitized by Google

word license is used in its broad technical sense in patent science; it does not mean a lease upon payment of a rental, but the absolute transfer of a property, which becomes vested in the licensee or purchaser *quoad* the result suggested by the nature of the invention and the extent of the purchase in point of number. Of course, if one or many of the public prefer to lease and agree to do so, there is no disability created by the law to prevent them from entering into such a contract. There are, in the nature of things, three sorts of contracts in relation to patents:—1st. The license to use, or by the purchaser furnishing himself with the means to use. 2d. The sale of the means to use the invention. 3d. The assignment of the whole or portion of the patentee's privileges. As tersely expressed by Judge Hall, in *Pitts* vs. *Hall* (2 Blatchford, 229): "a license, or assignment, or sale of a machine is a transfer *pro tanto*, of the property secured by the patent." In all these cases, however, it must be borne in mind that our Patent Act differs essentially from the English and the present American laws. Our patentees are bound to license, that is, to sell the use of their invention, and bound to see that their invention is not imported after twelve months, and that it be manufactured in Canada after two years, because connivance in an importation is equal to importing or causing to be imported. On the contrary, the English and American patentees are at liberty to import and at liberty to entirely withhold from the public use their inventions if they choose so to do; therefore, they can select their own conditions in a contract, in the nature of which they are bound, of course, when entered upon, but into which they are not forced by law. The instances of refusal to sell, which were the subject of evidence in this case, are several, but, with the exception of three, they are mixed or seem to be mixed with demands to use poles, wires, communication with lines and exchanges, which, naturally, the patentees are not bound to furnish. The three clear instances of refusal are: 1st, the case of Mr. Bate, of Ottawa, commenced in April, 1883; 2d, the case of Mr. Dickson, of Montreal, commenced in November, 1883; 3d, the case of Mr. Richard Dinnis, of Toronto, commenced in March, 1884. The correspondence is completed and certified by statutory declarations. In the case of Mr. Bate, he wrote on the 14th April, 1883, to the Bell Telephone Company of Canada asking them to give him their lowest price for three telephones, including transmitters, for a private line. He was answered by Mr. McFarlane that their agent at Ottawa was directed to call on Mr. Bate. Mr. Bate wrote a second letter to the company to explain that he wanted to purchase and not to rent the instruments. Mr. Sise, in answering this second letter, intimated to Mr. Bate the following: "We do not sell telephones, but we rent them." In the case of Mr. Dickson, a protracted correspondence took place, first opened with Mr. Scott, agent of the company, to be continued with Mr. Sise, in which Mr. Dickson insisted on his right to get the instruments as his property, according to law, and Mr. Scott and Mr. Sise declined to sell, but offered to lease or rent. To close the correspondence Mr. Dickson informed the company that being thus denied the purchase of the instruments, he had decided to have them constructed himself for his own use; to which threat Mr. Sise answered that they could not consent to an unconditional transfer, but would sell a Bell Telephone for thirty dollars, subject to the stipulation "that it is to be used only between certain specified points." In the case of Mr. Richard Dinnis, he wanted to purchase three sets of telephones to connect his office, his residence and his factory, and asked to be informed of the cost. Mr. Sise answered him that they had never sold these instruments, but that he (Mr. Dinnis) could have three sets rented at the rate of $20 per annum, he (Mr. Dinnis) building his own line; but that he would sell the instruments to him for $100 per set to be used only for the purpose stated by Mr. Dinnis. Mr. Sise refers Mr. Dinnis to Mr. Neilson, agent of the company at Toronto, for further information. Mr. R. Dinnis, in an interview with Mr. Neilson accompanied by Mr. Arthur Dinnis, both of whom render an account of the interview by statutory declarations, tried to get information from Mr. Neilson about prices, and asked if he could get the instruments at a more reasonable price and unconditionally, but was answered by Mr. Neilson that he could not give any other answer than the one contained in the letter of Mr. Sise.

The price was unreasonable and with a limitation of use. The case of Mr Bate was one of flat refusal. The two other cases were instances of protracted resistance, ended by offers to sell under restrictions, some of which were beyond the privileges of a patentee. The limitation as to where to use the invention, after purchase, is similar to a sale of a patented sewing machine to be used only in a particular house, or the sale of a patented plough to work only a given plot of land. The patent license in Canada accompanies the purchaser wherever he chooses to move on the wide territory of the Confederation, provided he does not use more than the number of articles purchased. The policy of refusal to license or sell, for the purpose of leasing at a rental, is made plain again by the answers, although very reticent, of the manager of the company to the interrogatories of counsel. A few quotations of his evidence will suffice:—"I do not think," says Mr. Sise, "there has ever been a set sold by us." "I would not swear that we have not refused to sell private telephones. I would not say we did." "I should not be able to say whether we had absolutely refused to sell unconditionally one or two or more instruments, nor would I say that we had not." "I do not think we ever sold an instrument unconditionally." The whole case is plain on the face of it; and it is also plain that the patentees or their representatives had in view to build up a commercial enterprise (for the benefit of the public as they contend), rather than to content themselves with getting their mere royalty on licenses or sales as patentees. With such intention, simply, there is nothing to find fault, so far as this tribunal is concerned, if the steps necessary to carry it out had not led them beyond the provisions of the Patent Act.

The conclusion is that the patentees, the respondents in this case, or their representatives, having extensively imported the patented articles, after the expiration of twelve months from the date of their patent; having not manufactured in Canada the said articles to the extent they were bound to do, after two years of the existence of their privilege; having resisted and refused to sell or deliver licenses as required by the statute, to persons willing to pay a reasonable price, for the private and free use of the patented invention, they have forfeited their patent.

Therefore, I decide that Alexander Graham Bell's Patent (No. 7,789) for "Bell's System of Telephony" has become null and void, under the provisions of section 28 of "The Patent Act of 1872."

J. H. POPE,
Minister of Agriculture.

Department of Agriculture,
Patent office, Ottawa, 24th January, 1885.

ANNUAL REPORT OF THE EDISON COMPANY FOR ISOLATED LIGHTING.

To the Stockholders of The Edison Co. for Isolated Lighting:

During the year ending November 1st, 1884, 143 isolated plants, aggregating 19,390 lights, have been installed, making a total, since the formation of your company, of 417 plants for 75,145 lights. These installations have been of almost every kind, as was explained in the last annual report, but during the present year the general depression of all manufacturing interests has seriously interfered with sales to factories, heretofore an important feature in your business.

In addition to permanent installations a profitable business has been done during the past year in renting plants to theatres, exhibitions, halls, &c.

The profits from lamp renewals have also been large, and they promise to increase from year to year.

Over two years ago a separate department was formed for conducting your business in New England. This department proved a source of heavy expense, exceeding $18,000 in a year and one quarter, without producing adequate returns, but subjecting your company to very serious losses from bad debts and other causes. As your Board could not see any reason whatever for its continuance, it was formally disbanded on July 1st, 1884, and the New England business is now conducted with profit through your New York office.

During the present year your company has been put to heavy expense for the purpose of taking part in several large electrical exhibitions, especially in one recently held at Philadelphia. Your directors felt bound to see that the Edison light was properly represented, but they now believe that the system is so well known, and its merits so generally recognized, that you can afford to hold aloof from many of these exhibitions, which, in themselves, do not produce any corresponding benefit. You can refer to the Edison light, whether isolated, underground, station or village plant, in actual operation, and your absence from these expensive exhibitions cannot any longer be misunderstood.

A source of constant trouble in the financial management of your company during the past year has been the heavy cash outlay incurred while each installation is in progress, and even after its completion, as payment is not made therefor until some time afterwards. The length of time which thus elapses is far greater than the credit which your company is allowed by the manufacturers of the machinery, &c., and for the *labor* of installing (a heavy item), cash must, of course, be paid. Furthermore, your company is obliged to carry a large stock of unemployed goods, to have them on hand for installations as required. Consequently, it may be said that the larger the business done by your company, the more difficult it becomes to make receipts take care of payments. Steps are in progress which, if successful, will correct this in part, but it is clear that your present paid-in capital is too small for your business, and it will be for your next Board to decide whether it may not be wiser to put the company in easier circumstances by making a further call for some part of your unpaid stock.

In the spring of 1884 negotiations were commenced between your Board and that of the Edison Electric Light Co., looking to the transfer to you of the business of exploiting and installing central station and village plants *within* the limits of gas territory. Such business *outside* of those limits already belonged to you un-

Digitized by Google

der your original contract with the parent company. On the first day of September last, a contract was executed between the two companies (after ratification by their respective shareholders), by which you undertook such exploiting and installing within gas limits, on a basis of an equitable division of profits; but as it was recognized that this new business would subject you to additional expense and *might*, possibly, not produce any adequate returns, the Light company agreed to make the dividends on the stock of your company held by it, secondary to the payment of dividends on your remaining stock, as is best explained by the following extract from the contract, as executed:

ELEVENTH. Whereas the Light company now owns fifty-one one-hundreths of the capital stock of the Isolated company, and, under its said contract with the Isolated company, dated April 26th, 1882, is entitled to receive, without additional compensation, a like proportion of all future increases of said capital, which provision of the said agreement, it is agreed, this contract does not in any way alter or disturb; and, whereas, the Light company consents, during the continuance of this agreement, and as further and special compensation to the Isolated company, to make certain concessions touching dividends on its said stock, in favor of the other stockholders, to wit, the holders of the remaining forty-nine one-hundreths (which stock, for convenience of designation, is herein called *cash stock*, as distinguished from the Light company's holdings, herein called *Light company stock*): it is agreed as follows, that is to say:

1. All net earnings of the Isolated company, applicable to dividends, shall, during the continuance of this agreement, be applied, first, to paying a dividend of, or dividends aggregating not more than, eight per centum per annum on the said cash stock; second, to paying a like dividend, or like dividends, on the Light company's stock, aggregating not more than eight per centum per annum; and, third, after the said dividends aggregating eight per centum per annum on both classes of stock shall have been paid, any surplus shall be distributed among all the stockholders according to holdings, including both the cash stock and the Light company's stock.

2. As to the said dividends, each year shall stand by itself, and no deficiency in any one year, whether as to dividends on the cash stock or on the Light company's stock shall be carried over to another year.

During the past year your company has met with active competition from numerous infringers on the Edison patents, who, encouraged by the inaction of the Light company, have become more and more emboldened, until many of them now exist as organized companies, working in opposition to your own. Your Board is happy to say that the Light company is now taking active steps to protect its patents in the courts, and there seems to be every reason to hope that speedy and favorable decisions will be secured, thus justifying your claim to the possession of the only practical system of incandescent lighting.

Your attention is invited to the balance sheet herewith, from which it will be seen that the net profits on business completed during the ten months ending November 1st, 1884, have been $60,-248.62.

The great depression in business throughout the country has, however, affected some customers whose accounts were taken over from last year as good. As your Board has not thought it expedient to carry forward any assets of doubtful value, all these accounts have been written off to profit and loss, although some considerable portion of them will, in all probability, be eventually collected. In the same way losses, which were not anticipated on the 31st December last, have since been ascertained on certain experimental installations of the previous year, and these have also been charged off. The operations in 1884 have been sufficiently profitable to admit of all this, and still leave a small balance at the credit of profit and loss, and your capital is intact, with all depreciated or worthless assets written off. Consequently there appears no reason to doubt that, with the safer methods of business now followed, your company will be able in future to resume the payment of regular and satisfactory dividends.

The authorized capital stock of your company is the same as at the date of your last report, namely $1,000,000, made up as follows:

Issued to Light company for license		$382,500 00
Paid for in cash		361,938 66
		$744,438 66
Unpaid installments		8,176 34
		$752,615 00
Still to be issued to Light company for license		127,500 00
Stock not yet called, viz., 50% of $245,000	$122,500	
Less already paid in full	2,615	
		$119,885 00
Authorized capital		$1,000,000 00

By order of the Board of Trustees,

E. H. JOHNSON, *President*.

65 Fifth Avenue, New York, November 18th, 1884.

ANNUAL REPORT OF THE EDISON ELECTRIC ILLUMINATING CO.

To the Stockholders of the Edison Electric Illuminating Co. of New York City:

Your company has now completed the fourth year of its existence, and your board feel that the results achieved are a fair cause for congratulation as to the past and for encouragement as to the future.

Your enterprise was one of peculiar boldness. Starting almost from the moment that Mr. Edison had demonstrated the scientific success of his great invention, you undertook to apply practically, and to its fullest extent, a system which had scarcely been tried at all, except in the laboratory, and which, so far as underground and central station work was concerned, existed only theoretically. When the construction of the present central station was commenced there were in use perhaps a half-dozen small, imperfect, isolated plants; and with only these to guide you, you undertook and have carried to scientific and financial success the great problem of underground central station lighting by electricity in competition with gas.

At the date of the last annual report the First District had scarcely more than reached the point where its receipts were in excess of its expenses. During each and every month of the present year they have shown a handsome increase as compared with last year, and instead of a loss, as in 1883, the operations of 1884 will leave a surplus of fully 3½ per cent on the capital stock, after paying expenses of every kind.

The following table shows in detail the average number of customers and of lamps connected, the collections, operating and general expenses (including all repairs and renewals), taxes, etc., and the profit or loss for each quarter of the years 1883 and 1884. It will be remembered that prior to February 1st, 1883, the light was supplied, as an experiment, free of cost to consumers.

Month.	Average of customers connected.	Average of lamps connected.	Collections.	Operating and general expenses.	Loss.	Profit.
1883.						
Feb. March...	330	4,374	$3,788 64	$9,904 48	$6,115 84	....
Ap. My. June.	398	5,931	8,711 89	14,752 28	6,040 39	....
Jly. Aug. Sep.	439	8,685	15,689 01	15,197 31	....	$491 70
Oct. Nov. Dec.	483	10,172	24,900 11	17,693 08	....	7,207 08
1884.						
Jan. Feb. Mar	498	10,685	28,659 34	18,229 88	....	10,429 46
Ap. My. June.	541	11,594	25,400 54	18,148 97	....	7,251 57
Jly. Aug. Sep.	582	12,503	23,849 34	19,975 88	....	3,873 46

The financial results of the foregoing table are summarized in the following:

	1883.	1884.
February and March	$6.115 84 loss*	$10,429 46 profit
April, May and June	6,040 39 loss	7,251 57 profit
July, August and September	491 70 profit	3,873 46 profit
October, November and December.	7,207 08 profit	14,000 00 profit†
Net loss, 1883	$4,457 50	
Net profit, 1884	....	$35,554 49

* For two months only. The loss for three months would be even larger.

† The profits for December are estimated at	$5,500 00
The actual profits for October and November were	8,500 00
Making the estimated total for the quarter, as above	$14,000 00

As a matter of course, the profits of the station fall off considerably in the summer months, as will be seen from an examination of the foregoing tables. To neutralize this falling off in part, your company has undertaken to furnish electric motor fans to be run by current from the central station; and while their introduction last summer was not possible until too late to secure any considerable results, the fans met with such favor as to warrant the belief that next summer they can be developed into an appreciable and permanent source of revenue.

A heavy item in the operating expenses of the First District has heretofore been that of lamp renewals. Owing to imperfect electrical determinations in the construction of the district, and the consequent inequality of electrical pressure, the lamp breakage was unduly heavy. It is very gratifying to state that during the past summer these defects of construction have been mostly corrected, and improvements have also been made in the lamps themselves, with the result of raising the life of lamps from 400 hours of use in January to 914 hours in November, which is equal to a monthly saving of about $400 in operating expenses on the number of lamps in use at the present time.

The average monthly life of lamps during the past year, as

Digitized by Google

reported by the superintendent of the station, has been as follows:

January	400 hours of use
February	523 " "
March	349 " "
April	448 " "
May	400 " "
June	389 " "
July	502 " "
August	558 " "
September	727 " "
October	730 " "
November	914 " "

The following additions have been made to construction account of the First District since January 1st, 1884:

New plant, including 2 engines, 150 h. p. each; 2 dynamos, 1,200 lights each; 2 regulators, and expenses of installing same	$34,125 08
Station apparatus	1,123 01
Street conductors, viz., 3,849¼ feet	17,140 39
House connections and original lamps	2,958 41
Meters	133 31
Tools and implements	22 68
Motors	2,439 00
Office fixtures	59 38
Total	$58,001 16

The expediency of these expenditures, which have only been made after careful deliberation, is best shown in the financial results achieved, which are due in a considerable degree to the fact that the increased expense of running the station as enlarged, bears but a small proportion to the increase of receipts secured by the enlargement. The station is even now taxed to its utmost capacity, and it is evident that further additions to the existing plant could be made with substantial advantage to the company. In fact, the superintendent of the station reports that there are now on file over 100 applications for the light, of which at least 50, requiring about 750 lamps, would furnish very desirable customers.

Notwithstanding the recent reduction of the price of gas from $2.25 to $1.75 per 1,000 cubic feet, our First District station has not yet lost a single customer, which is the best possible proof that our light, at its present cost (1¼ cents per hour of use for lamps of 16-candle power), is found more desirable and satisfactory than gas even at the reduced price.

Of even greater importance, however, than the enlargement of the First District is the question of starting a district up-town. When your company was organized it was believed that its authorized capital would be sufficient to install both an up-town and a down-town district, but the delays and difficulties encountered with the down-town district were so great that the capital proved insufficient to install it alone, and even now your company finds itself in debt to the Light company for more than $70,000 for money advanced and balance of license, though against this your company claims certain offsets arising from the increased cost of the First District. In fact, the down-town district has been operated in the face of every possible disadvantage; but your board has believed that it was pursuing the right policy in showing what could be done under all these unfavorable circumstances, hoping thereby to shorten the time when it could enlist the necessary capital for work up-town.

The present district, which is bounded by Wall street, Broad street, Exchange place, Broadway, Spruce street, and the East River, is perhaps the least remunerative in the city, being occupied mainly by banking and other offices, which are closed on an average earlier than 6 o'clock, so that the hours of light consumption are very short.

A far richer field for your enterprise would be an up-town district, extending perhaps from 23d street to the Central Park, and from the 8th to Madison avenues. Not only would the hours of light consumption be much longer, but, owing to the great cheapening now made in the cost of everything connected with the Edison system, the cash capital required entirely to install and equip a station of light-giving capacity equal to the present one (and situated somewhere within the limits indicated) would be, as appears from preliminary estimates already made, not over one-half the amount spent for the down-town station. It is estimated that during the coming year this latter will earn fully 5 per cent on its stock, or equal, in other words, to 10 per cent on the cost at which it could now be duplicated. In an up-town station, where there would be longer hours of light consumption, it seems very reasonable to assume that half again as much profit, or at least 15 per cent net per annum at the start, could be earned; and were it not for the general depression at present affecting all electric light investments, embracing both the good and the bad, your trustees would not hesitate to come before you at once with some scheme to raise the capital for a large up-town installation. In all probability considerably more than 15 per cent. could be earned in an up-town district, but even on this basis it is felt that with the results already achieved in the First District, the time is near when a successful plan can be formulated for an up-town station, and as soon as one large station is started up-town there can be no doubt that the extension of the system throughout the entire city of New York will follow.

Your present capital stock is the same as at the date of the last report, viz., $1,000,000, made up as follows:

Paid in	$987,010
Unpaid subscriptions	11,490
Stock in treasury	1,500
	$1,000,000

As the fiscal year of the company ends on the 31st of December, it is recommended that the time for the annual meetings in future be changed to the third Tuesday in January, when the actual results of each previous twelve months can be presented in their entirety, without the necessity for partial estimates which at present exists.

By order of the Board of Trustees.

S. B. Eaton, Vice-President.

OPINION OF JUDGE SHIPMAN IN THE PRINTING TELEGRAPH CASE.

This is a motion for a preliminary injunction against the alleged infringement of reissued Letters Patent, No. 3,810, dated January 25th, 1870, granted to the Gold & Stock Telegraph Co., as assignees of Edward A. Calahan, for an improvement in telegraphic printing instruments for registering gold, stocks, &c.

The original patent was granted April 21st, 1868. The reissued patent contains five claims, the second of which is said to be infringed by the defendants by the use of a patented machine invented by Stephen D. Field.

No adjudication has been had upon the Calahan patent, except the case, in this court, of the present plaintiff against Charles J. Wiley, wherein the validity of the 3rd claim only was involved. The principal question in this case, viz.: as to the construction of the words "jointly or separately" in the second claim, did not arise in the Wiley case.

The present bill was filed on May 29th, 1883, at which time the defendant, had 20 Field printing instruments in process of construction. Before that time they had used the instrument for the purpose of experiment. The plaintiff's *prima facie* case was closed on July 23rd, 1884. The difficulty of ascertaining and proving the construction of the Field machine was a cause of delay.

Therefore, no testimony has been taken by the defendants, although the time designated by the court in which to take and close their proofs has expired. They have presented before me divers affidavits in which their defense is set forth.

The principal question in the case is the construction of the word "jointly" in the second claim, and when I add that it is substantially agreed that the state of the art in 2-wheel printing, at the date of the original Calahan patent, is represented in the Johnson or Theiler mechanism, the question may seem to be a very simple one, but the plaintiff's proofs and the defendants' affidavits show that it is really one upon which much learning, skill and time may be profitably employed, and which is not of ready solution.

The reason why the motion is pressed, under this state of facts, is obvious and is not concealed. The Calahan patent will certainly expire on April 21st, 1885. It is said by the defendants that it will expire on March 16th, 1885, by reason of the expiration at that date of the English patent for the invention. Necessary delays have occurred in the taking of the plaintiff's *prima facie* proofs. The defendants have not been in haste in taking their testimony and the life of the patent is rapidly approaching its close. There is a strong and very urgent motive to have a decision upon the question in the case before the invention is open to the public.

Assuming that the whole testimony is before the court, and that it has been completely presented and can be thoroughly studied on this motion, the fact still remains that a temporary injunction is being sought upon a question which now arises for the first time and which must be examined with the care and patience necessarily incident to a case wherein men's minds must differ. In other words the attempt is made to make a motion for a temporary injunction applicable to a state of facts to which such a motion is not adapted.

It is no answer to the argument that upon a motion for an injunction, *pendente lite*, the question must be susceptible of ready answer and the case must be free from reasonable doubt, to say that this whole case is now before the Court, and that the questions, after the state of the art is ascertained, are those of law which can be settled as well now as at final hearing, because a motion for a temporary injunction is not designed for the adjudication of doubtful questions which have not previously been discussed. While I understand the pecuniary damage to the plaintiff arising from delay, if its rights are being infringed, the history of the case shown and my examination of it satisfies me that the question is one which is open and which needs the attention usually to be given to cases upon final hearing.

The motion is denied.

THE TELEPHONE INTERFERENCE CASES.

The proceedings in interference involving the question of priority of invention of the speaking telephone, which have been pending in the Patent Office since March, 1878, were decided by the Examiner of Interferences in the first instance on most of the issues involved in favor of A. G. Bell; but J. W. McDonough was awarded priority on one important point, which substantially covered the magneto-receiver. The claim in dispute is as follows: "A telephonic receiver consisting of the combination in an electric circuit of a magnet and a diaphragm supported and arranged in close proximity thereto, whereby sounds thrown upon the line may be reproduced accurately as to pitch and quality."

Upon appeal to the Board of Examiners-in-Chief, this decision was reversed and priority awarded to Bell. McDonough then appealed from the decision of the Board, and a hearing has been had before the Commissioner of Patents on the appeal. McDonough's counsel moved to reopen the case and remand it to the primary examiner, on the ground that new evidence had been discovered to the effect that the telephone could transmit articulate speech by means of an interrupted current. It was also contended that the Board had decided against McDonough on the ground that his instrument was not operative, whereas the question of the operativeness of the instruments was not within their province to determine, and that therefore the decision of the Board was invalid. The motion was overruled by the Commissioner, who held that it was competent for the Commissioner on appeal to remedy any invalidity of the decision of the Board, and also for the reason that the motion had been filed without due notice to opposing counsel. William L. Voelker also appealed from the decision of the Board awarding priority to Bell in interferences A and B, and against Edison in interference No. 1. Elisha Gray also appealed from the decision in favor of Bell in case G. Several eminent counsel appeared in behalf of the contestants,—Chauncey Smith and J. J. Storrow for Bell, Colonel Dyer for Voelker, W. D. Baldwin for Gray, Roscoe Conkling for Edison, and General S. A. Duncan for McDonough. The decision of the Commissioner had not been announced up to the time of going to press.

STATE TAXATION OF TELEGRAPH COMPANIES.

On January 20th, the Court of Appeals of New York state rendered an important decision upon the question of the right to tax the entire capital stock of a telegraph company under the statute of 1881. The Western Union and Gold and Stock Telegraph companies have for 3 years resisted the payment of the whole tax levied on dividends declared. They maintained that a tax could not be collected on the dividends on the whole capital stock of the company, but only on the value of the property in the state. They paid the amount due on property situated in New York state, but have fought the payment on the whole capital through all the courts. They argued that the telegraph law of 1861, and not the corporation tax law of 1882, applied to them, while the State Comptroller and Attorney-General held that the tax must be raised on the entire dividend declared. In the Western Union suit Judge Samuel Hand, of Albany, who was referee, gave judgment for the state and sustained the doctrine that the whole capital stock could be taxed, as the law of 1861 was virtually repealed by that of 1882. Appeals were taken through Term, on this and the Gold and Stock Telegraph case to the Court of Appeals. The principal argument was made on the latter, as the Gold and Stock party thought their position was stronger than in the Western Union suit. The Court of Appeals decided in favor of the state. The judgment of the lower courts, so far as it allows interest, is modified, and as modified the judgment is affirmed. All the judges concur except Chief Judge Ruger, who was not sitting. The amount involved is, according to Attorney-General O'Brien nearly $1,000,000.

TEMPORARY STOPPAGE OF THE HELL GATE LIGHT.

The electric light at Hell Gate went out on Saturday morning, Jan. 3, at 4 o'clock, and the brilliant illumination was withheld until Tuesday evening. The stoppage of the electric light was caused by the fact that a part of the screws attaching the armature to the shaft gave signs of being loose. The attendant engineer, noting this, decided that it would be advisable to cut off the light. Owing to the circumstance that there was a lack of proper tools, such as those which are in use at the Cleveland factory, the repairs occupied the time from Saturday until Tuesday.

"Since the light was first placed at Hell Gate last November," said Mr. C. P. Whitney, Secretary of the Brush-Swan Electric Light Company, "there have been no mishaps worth calling by the name. Once a couple of globes were broken by a bird and the lights went out. Of course the weather has once or twice occasioned annoyance. One night the lights went out, owing to the presence of sleet on the elevator, which kept the attendant from going up. The government is perfectly satisfied with the apparatus and its workings, and the plant has been fully settled for."

Mr. Whitney stated that a duplicate apparatus had already been ordered, so that such a delay in electric lighting of Hell Gate could never occur again. "The original objection of the pilots," he said, "which was not very general, is, we are assured by the government officers, entirely removed. During the nights in which the lights were out, there were many complaints from parties using the water about Hell Gate. Great regrets were expressed at the absence of the lights. Some of the captains of the Sound boats, I have been told, have concluded that it was a very great advantage to have the Hell Gate electric illumination, and that it was materially useful in navigation. It certainly is," concluded Mr. Whitney, "a permanent institution, and is now generally understood to be such."

AFFAIRS OF THE BANKERS AND MERCHANTS' TELEGRAPH CO.

A Referee in the suit of Alexander H. De Haven, a stockholder, against the Bankers and Merchants' Telegraph Co. and its Receivers, who were appointed in the sequestration suit brought by Austin G. Day, a judgment creditor of the company, Thomas S. Moore reported last month that the Receivers should be allowed to issue $1,500,000 of certificates, which should be a first lien on the company's property, and the proceeds of which should be used in settling all claims against the company, excepting those of the holders of its mortgage bonds. In his report, Referee Moore stated that the Bankers and Merchants' company had in its treasury $99,000 of the bonds under the mortgage of $10,000,000 given by it to the Farmers' Loan and Trust Co.; $5,115,000 of them were in the hands of purchasers, and $4,786,000 of them were pledged as security for its notes representing $784,874.18. Besides the notes last mentioned, the company owed $372,209.37 to unsecured creditors for work and material, $145,000 on coupons of bonds of the Southern, and American Rapid Telegraph companies, both of which corporations it controls; $290,000 on bonds issued under a mortgage of the New York and Washington line, $8,700 as interest on those bonds, $4,800 for taxes, $130,000 on Receivers' certificates, issued to enable the Receivers to get possession of certain Western branch lines, and $97,000 borrowed money, for which the Receivers are yet to issue certificates. The $130,000 of certificates were made special liens on the property they were issued for.

Referee Moore also reported that if the gap between Hammondsport, Ill., and Chicago, and that between Meridian, Miss., and New Orleans, were closed, as they could be readily and cheaply, as the material for the connecting lines was on the ground, the business of the company would be greatly benefited. In Referee Moore's opinion, Receivers' certificates, if made a first lien on the property of the company, could be sold for par, or not less than 90, and that the proceeds of the sale of $1,500,000 could be made to redeem every liability of the company, excepting the bonds issued under the ten million dollar mortgage. Judge Donohue has made an interlocutory decree reappointing Messrs. Newcomb and Smith as Receivers of the company, and authorizing them to issue the certificates representing $1,500,000.

THE BELL TELEPHONE PATENT IN CANADA ADJUDGED VOID.

We mentioned in our December number that the Toronto Telephone Manufacturing Co. had commenced proceedings in the Patent Office of the Dominion of Canada, to set aside the patent of Alexander Graham Bell, of August 22, 1877 (No. 7,789), and declare it void under the provisions of section 28 of the Act of June 14th, 1872, respecting patents of invention. This section is as follows :—

> Every patent granted under this act shall be subject and expressed to be subject to the condition that such patent and all the rights and privileges thereby granted shall cease and determine, and the patent shall be null and void at the end of two years from the date thereof, unless the patentee, or his assignee or assignees, shall within that period have commenced, and shall, after such commencement, continuously carry on in Canada the construction or manufacture of the invention or discovery patented, in such manner that any person desiring to use it may obtain it, or cause it to be made for him at a reasonable price, at some manufactory or establishment for making or constructing it in Canada, and that such patent shall be void if, after the expiration of twelve months from the granting thereof, the patentee, or his assignee or assignees, for the whole or a part of his interest in the patent, imports, or causes to be imported, into Canada, the invention for which the patent is granted ; and provided, always, that in case disputes should arise as to whether a patent has or has not become null and void under the provisions of this section, such disputes shall be settled by the Minister of Agriculture or his deputy, whose decision shall be final.

The defendant, in the first instance, unsuccessfully endeavored to procure a writ preventing the Minister of Agriculture from hearing the case, on the grounds that it was *ultra vires* of the Dominion constitution. The case came up on November 24th, and the hearing was continued on December 2d, 1884. On January 25th, 1885, a decision was rendered by the Minister of Agri-

Digitized by Google

culture, declaring the patent void. The full text of the decision is given elsewhere.

The evidence taken in the case is said to have filled 1,500 pages, all of which has been carefully gone over by Dr. J. C. Tache, the deputy of the Minister, who is an expert in patent law.

At the time of the decision an action for damages was pending against the Dominion Telephone Co., on the allegation of infringment of this patent, which had been brought by the Bell Telephone Co. of Canada.

A GAS COMPANY ADOPTS ELECTRIC STREET LIGHTING.

A company was formed in Lockport, N. Y., about two months ago to introduce electric lighting, and it obtained from the city government the right to erect poles and string wires in the streets. After this the gas company, a monopoly of long standing, bought a controlling interest in the electric company, and it was thought this would end the electric light business, but on Jan. 12 a new company appeared before the common council and obtained the privilege to light several streets by electricity in place of gas. On Jan. 16 in the midst of a driving snow-storm the gas company commenced with a large force of men to pull down their gas posts and put up electric poles in place of them in Main street, which right had already been given by the council to the new company. A war of words between officers of the two companies occurred, but work was continued without interruption. Trouble is expected in the future.

PROGRESS OF INCANDESCENT LIGHTING.

Since writing the editorial on "Isolated Electric Lighting Plants," which appears in this issue, we have obtained the following information showing that there already exists a very considerable demand for this very class of work.

In this city, the United States Illuminating Co. has erected a plant of 1,800 incandescent lamps for the "Chelsea" apartment house, 500 for the building on upper Broadway, occupied by Aitken, Son & Co., and A. A. Van Tine & Harris; also 120 for Oppermann's Brewery on 45th street.

Contracts have also been closed by the same company with the Union Ferry Co., for lighting 2 of its new boats on the Fulton line with 75 lamps each, Cyrus W. Field's new Washington building on lower Broadway with 900, and the new station of the Pennsylvania R. R. Co. at Jersey City with 600 lamps. It will be remembered that the former station was destroyed by a fire originating from a gas explosion, the loss being estimated at $500,000. Attention was directed to this in our September issue in an editorial on the "Comparative Safety of Electric Lighting."

If the large gas consumers would devote more attention to this subject, they would doubtless effect greater reforms in the gas service than by holding indignation meetings, as was done on the 27th of January, with the vain hope of securing relief through legislative measures.

LAKE SUPERIOR COPPER ORE MINES.

The output of copper ore from the mines of Lake Superior for the year 1884 was as follows: Calumet and Hecla, 24,997 tons, being an increase of 4,372 tons over 1883; Quincy, 3,447; Franklin, 2,302; Osceola. 2,508; Atlantic, 2,199; Allouez, 1,371; Huron, 1,192; Central, 1,031; Peninsula, 865; Conglomerate, 841; Copper Falls, 606; Hancock, 461; Phœnix, 482; Wolverine, 440; Grand Portage, for five months, 154; Pewabic, 141. Product of all the Ontonagon County mines is estimated at 500 tons. The total products foot up 43,537 tons, an increase over 1883 of 6,052 tons. This ore will yield from 78 to 80 per cent. of fine copper after smelting. The mines are generally in good condition, but the unprecedentedly low price of copper has a depressing influence on all mines. This has already led to the suspension of work by the Peninsula, formerly the Albany and Boston, mine. On the other hand, the Conglomerate has resumed work, to be continued until spring. The property of the Pewabic has been sold to satisfy an execution issued at the suit of James H. Seager, S. D. North, of the Quincy mine, being the purchaser. The dividends paid last year were as follows: Calumet and Hecla, $1,300,000, making a total of $25,650,000 since its organization. Quincy, $280,000; total, $3,867,000. Central, $40,000; total, $1,710,000. Osceola, $625,000; total, $972,500. Franklin, $80,000; total, $348,000. Atlantic, $40,000; total, $260,000.

ERROR OF A NEWS AGENCY.

Considerable excitement was created among the oil brokers on January 20th by the report sent over Kiernan's Financial News printers that "the McCalumet Oil Company, of Pittsburg, the second largest oil company in the United States, has just made an assignment." The McCalmont was the company generally understood to be referred to, the name "McCalumet" evidently being an error of the tape. The secretary and treasurer of the company promptly denied the truth of the report and stated that the concern was in good condition and had reduced its indebtedness over $500,000 in the last nine months. Later the same officer furnished this statement:

> The false rumor was circulated over the tickers this morning that the McCalmont Oil Company had failed. The company promptly denied the report, set to work to discover its authors, and instructed its attorney, John Brooks Leavitt, to institute a suit for libel against Kiernan & Co., the owner of the ticker, for publishing the report, and also a suit against Knoblauch & Co., and C. I. Hudson & Co. for conspiracy in spreading it.

TROUBLE AVERTED.

The receivers of the Bankers' and Merchants' Telegraph Co. were presented with the following memorial, January 16th:

> "The employees of this company earnestly protest against receiving our salaries on the instalment plan, which has been in vogue for some months past. Money is still due us for the month of December and January, and the majority of us have incurred debts for the necessaries of life which must be met at once. Recognizing the fact that the law gives remuneration for labor performed preference over all other debts, we insist that you devise means for settling with us in full up to Jan. 16, on Tuesday, Jan. 20."

Checks were prepared in accordance with this request for all arrearages up to January 1st, otherwise, as is generally understood there would have been a general withdrawal from the service.

PROGRESS OF THE TWENTY-FOUR-O'CLOCK MOVEMENT.

At the annual meeting of the American Society of Civil Engineers, the committee on standard time reported that it had communicated with a number of prominent men in all parts of the country, and that 92 per cent. were decidedly of the opinion that the hours should be counted in a continuous series up to 24. Out of 171 railroad officials 98 per cent. were in favor of the change. Telegraph interests were reported to be in full sympathy with the movement, President Green being given as authority for the statement that besides reducing the number of errors, the transmission of fully 150,000,000 letters would be annually saved.

ELECTRIC LIGHT AND POWER.

Domestic.

Quincy, Ill., and Trenton, N. J., are among the cities which now have their streets lighted by electricity.

The Newton (Iowa) Electric Light Co. has filed articles of incorporation with the Secretary of State. Capital stock, $25,000.

The works of the Crump Label Co., at Montclair, N. J., are now lighted by 300 Weston incandescent lamps, and the Favorite Mills at Jersey City by 250 of the same.

The Electric Light Co. of Dubuque, Ia., having discovered that it has been losing $1,000 per annum, resolved at a late meeting to discontinue its lights, and offer the plant for sale at half price.

Atchinson, Kansas, after ten days' experience with the electric light, developed such a demand for more of the same that the local company has arranged to double its capacity.

The works of the Gilbert Manufacturing Co. at Ware, Massachusetts, are now lighted by arc lamps, which are said to be preferred to the incandescent.

The H. C. Frick Coke Co., of Connellsville, Pa., has been making experiments on the incandescent electric lamp for use in the mines. The principal point to be determined is the cost of the light. The electric light is also being introduced in some of the Schuylkill county mines.

The following tariff decision is of interest to colleges: "Dynamo-electric machine, although adapted, as claimed, for use in a college to produce illumination for projection of pictures on a screen in illustration of subjects of instruction, is not dutiable as a philosophical instrument, but is subject to a duty of 40 per cent. ad valorem as a manufacture of metal." (Letter to the Collector of Customs at Boston.)

W. H. McGrath, superintendent of the Brush Electric Light Co. in New York city, says "We run from our two stations 1,300 arc lights, 344 for city lighting, the remainder for private use. To do this requires fifty dynamos, 1,400 h. p., and over 300 miles of wire. In our stations we never had an accident. On December 20, the New York company was five years old. Some of the machinery has been in almost continuous use since 1879, and without apparent depreciation. New York streets will soon all be lighted by electricity. No one corporation could afford to put its own wires underground. There is, however, little to hinder except the expense. Our business is a profitable and growing one. The chief advantage we have over gas plant in the manufacture of light is on the score of labor, coal and the matter of depreciation of which I spoke. We can get a h. p. by the consumption per hour of 2 3-10 pounds of, say, $3 coal."

Digitized by Google

Foreign.

The *English Mechanic* doubts whether the elevated railways will be operated by electricity for some years to come.

The electric light, says the *Dyer*, is being introduced into many of the dyehouses of Bradford (England) with great success, and affords a cooler and purer air than gas. The arc light is found to be useful for matching shades, whilst the incandescent lamp is of use in grey rooms, cleaning rooms, &c., where benzine is employed, or in any place where there is danger of fire.

The Société Espagnole d'electricitie de Barcelone has now in operation in different cities and towns in Spain, 504 arc, and 924 incandescent lamps. Of these, 185 arc and 281 incandescent lamps are in the city of Barcelona.

Austria is going into electric railways on a liberal scale, an extensive system of communication being planned, at a cost of 7,000,000 florins. The house of Siemens & Halske, which has done so much for the devolopment of the industrial uses of electricity, is to construct the projected system.

ELECTIONS AND APPOINTMENTS.

The Standard Multiplex Telegraph Co. has elected as directors Clement A. Griscom, James D. Potts, Frank T. Frith, Franklin Jones, Wendell Goodwin, M. T. Pickering, P. H. Delany; President, Clement A. Griscom; Vice-President, Wendell Goodwin; Treasurer, W. H. Barnes; Secretary, E. A. Calahan.

The Commercial Telegram Co. has elected the following directors: J. H. Prall, Richard S. Newcombe, Geo. H. Pell, John B. Scott, A. H. DeHaven, Charles E. Quincey, Geo. Turnbull, J. V. Bonhier, Geo. L. Hutchings, James G. Smith, J. G. Case, G. S. Mott, S. D. Field, A. H. Baldwin and C. Mingesheimer.

MISCELLANEOUS.

At a recent meeting of the Franklin Institute, it was stated that the electric fire-damp indicator had been tried with signal success, in some West Virginia mines. This indicator is the invention of a Cincinnati mechanic.

MANUFACTURING AND TRADE NOTES.

The Western Electric Co. is making at the Chicago factory a multiple switch-board for Stockholm, Sweden; putting in a 50-light plant for the Western Indiana depot, Chicago; a 25-light plant for Commodore Davidson's new opera house and skating rink, St. Paul, Minn., and another 25-light plant for Rand, McNally & Co., Chicago. This company recently shipped a 12-light plant to Antwerp, Belgium, and a 12-light plant to South Melbourne, Australia. In the other branches of business it is fitting up the new Montezuma Hotel, at Las Vegas, New Mexico, the new Windsor Hotel, New Orleans, La., and Hotel Royale, at same city. The works are running full time.

PERSONAL MENTION.

Prof. T. C. Mendenhall has been appointed Chief Electrician of the U. S. Signal Bureau.

RAILWAY SERVICE.

A complete set of electric railway signals has been presented to the Massachusetts Institute of Technology by the Union Switch and Signal Co.

THE TELEGRAPH.

Domestic.

Wm. O. Ross, a stockholder of the Baltimore & Ohio R. R. Co., has brought suit against that corporation in the U. S. Circuit Court at Baltimore, to ascertain the amount of money advanced by it, and on what authority, for the purpose of constructing and operating its telegraph system. He believes $3,000,000 has already been expended.

Foreign.

The telegraph wires are carried through the Alberg tunnel by 4 cables containing in all 14 wires. They weigh 150,000 lbs. and cost nearly $40,000. Two are cased with iron, one with lead, and are placed in a carefully protected channel below the track level. The fourth, with but one wire for railroad signaling, is suspended above ground.

THE TELEPHONE.

Domestic.

The Magic Telephone Co. has been incorporated by Samuel E. Landis, Wilbur F. Hoffman, and Josiah Bryan. It is to have a capital of $500,000.

Judge Nixon, at Trenton, has issued a preliminary injunction restraining the New Jersey Overland Telegraph Co. from constructing, using or selling the patented improvement of the American Bell Telephone Co. till the further order of the court. It is said that the company has notified its subscribers that their service must be suspended.

The Globe Telephone Co. has filed articles of incorporation in the county clerk's office, Camden, N. J. The capital stock is $500,000, and the incorporators are James Work, Thomas E. James, Thomas H. Leigh, of Philadelphia, and W. W. Goodwin of Camden.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER *by* Pope & Edgecomb, *Solicitors of Patents for Electrical Inventions*, 59 *Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From December 23, 1884, to January 20, 1885 (inclusive).

Alarms and Signals:—*Circuit-closer for Alarms*, A. Lungen, 309,790, Dec. 23. *Fire Alarm Box*, W. C. Hess, 310,424, Jan. 26. *Burglar Alarm*, W. F. H. O'Keefe, 311,027, Jan. 20.

Clocks:—*Secondary*, G. and F. Trippen, Jr., 309,809, Dec. 23. *Time Indicating Apparatus*, J. C. Wilson, 310,106, Dec. 30. *Electro Pneumatic System*, C. A. Mayrhofer, 310,530, Jan. 6.

Conductors, Insulators, Supports and Systems:—*Joining Conduit Sections*, B. Williams, 309,907, Dec. 30. *Insulator*, H. L. James, 310,059. *Binder for Electrical Conductors*, J. Brady, 310,177, Jan. 6. *Manufacture of Conductors*, A. A. Cowles, 310,258. *Metallic Curbing for Containing Wires*, P. H. Griffin, 310,271. *Conductor*, H. C. Watt, 310,345. *Press for Manufacture of Insulators*, G. W. Weyman, 310,484. *System of Electric Lighting*, O. Gassett, 310,663, Jan. 13. *Apparatus for Distributing Electricity*, same, 310,664. 310,665. *Protector for Underground Pipes*, W. R. and J. M. Rowbottom, 310,727. *Underground Housing and Insulation for Conductors*, E. C. Townsend, 310,748. *System of Generating and Regulating Currents*, E. Weston, 310,763. *Conduit Pipe*, T. Bacmeister, 310,773. *Machine for Making Compound Wire*, J. W. Ells, 310,805. *Cable*, H. A. Clark, 310,879, Jan. 20. *Device for Securing Wires to Poles*, G. L. Broomhall, 310,931. *Suspension of Aerial Cables*, E. T. Gilliland, 310,938. *Art of Making Wire*, T. Midgley, 310,956. *Manufacture of Insulating Compound*, A. Muirhead, 310,957. *Apparatus for Manufacturing Compound Wire*, M. G. Farmer, 310,993. *For Coating Wire with Metal*, same, 310,994. *Process of Manufacturing Compound Wire*, same, 310,995. *Lightning Conductor*, J. R. Fricke, 311,115. *Connection for Conductors*, E. H. Johnson, 311,130.

Dynamo Machines and Motors:—*Motors*, W. H. Chapman, 309,522, Dec. 23; C. C. Peck and W. H. Chapman, 309,562. *Regulator for Generators and Motors*, W. K. Freeman, 309,536; B. F. Orton, 311,141, Jan. 20. *Armature for Dynamos*, B. F. Orton, 309,560, 309,735, Dec. 23; C. F. Brush, 310,876, Jan. 20. *Dynamos*, E. Weston, 310,762, Jan. 13; H. R. Boissier, 310,782. *Brush Holder for*, same, 310,780.

Galvanic Batteries:—E. Weston, 310,004, Dec. 30, W. K. Kidder, 310,831, Jan. 13. *Galvanic Polarization Battery*, C. A. Faure, 309,939, Dec. 30.

Ignition:—*Gas Lighter*, A. R. Molison, 309,971, Dec. 30; C. W. Weiss, 310,002.

Lamps and Appurtenances:—*Arc Lamps*, J. B. Allen, 309,816, Dec. 30; A. Davidoff, 310,124; L. G. Woolley, 310,630, Jan. 13; S. H. Short, 310,736; N. McCarty, 310,837; W. Hochhausen, 311,073, Jan. 20. *Focusing Arc Lamp*, W. Hochhausen, 311,074. *Voltaic Arc Lamp*, W. P. Patton, 311,142. *Regulator for Lamps*, C. L. Buckingham, 310,119, Dec. 30; H. P. Boissier, 310,781, Jan. 13. *Cut-out for Lamps*, same, 310,783; W. Hochhausen, 311,072, Jan. 20. *Incandescent Lamp*, O. A. Moses, 310,145, Dec. 30; C. A. Hussey, 310,516, Jan. 6. *Holder for*, T. W. Bryant, 310,373. *Socket for*, S. Bergmann, 311,100, Jan. 20. *Thermal Cut-out*, W. Stanley, Jr., 310,472, Jan. 6. *Manufacture of Incandescents*, E. Weston, 310,761. *Combined Gas and Electric Light Fixture*, P. H. Klein, 311,131, Jan. 20. *Illuminating Point for Electric Light*, C. F. Brush, 10,544 (re-issue), Dec. 23.

Measurement:—*Measuring Apparatus*, M. G. Farmer, 309,937, Dec. 30; J. Canderay, 310,252, Jan. 6.

Metallurgy:—*Process of Separation for Metals*, B. Moebius, 310,302, Jan. 6. *Apparatus for Separation and Deposit of Metals*, same, 310,533.

Miscellaneous:—*Apparatus for Operating Bolts*, W. Vogel, 309,585, Dec. 23. *Device for Applying Electricity to the Human Body*, 309,897, Dec. 20. *Dental Plugger*, J. H. Van Ness and M. A. Bland, 310,099. *Thermo electric Pad*, S. G. Kram, 310,140. *Plating Basket*, A. Murphy, 310,146. *Mariners' Compass*, J. Scotland and F. Cordon, 310,729, Jan. 13. *Dumb-bell*, J. H. Shaw, 310,733. *Electro-magnetic Clutch*, W. A. Rogers, 310,913, Jan. 20. *Shuttle Operating Mechanism*, E. S. Winchester, 310,970.

Railways and Appliances:—*Railway*, F. H. Dauchell, 309,606, Dec. 23. *Visual Signal*, F. M. Godfrey, 310,412, Jan. 6. *Signal*, C. R. Johnson, 310,519. *Railway System and Car*, M. H. Smith, 310,962, Jan. 20. *Railway Yoke*, C. Bullock, 310,558, Jan. 13. *Single Rail Circuit for Signals*, H. D. Winton, 311,050, Jan. 20.

Storage Batteries:—C. A. Faure, 309,838, Dec. 30; W. A. Shaw, 309,886; L. H. Rogers, 310,724, Jan. 13, S. Kalischer, 311,007, Jan. 20, 311,006.

Telephone Systems and Apparatus:—*Call-box*, E. Gray, 309,617, Dec. 23, *Microphone*, F. J. Semal, 309,742. *Switch*, J. D. Lyle, 309,791; F. W. Harrington, 310,890, Jan. 20. *Telephones*, 310,068, Dec. 30; H. E. Waite, 310,751. Jan. 13; H. P. Pratt, 310,961, Jan. 20. *Telephonic Apparatus*, T. F. Taylor, 310,094, Dec. 30. *Transmitter*, J. H. Rogers, 310,151. *Signaling Apparatus*, J. H. Cary, 310,379, Jan. 6. *Telephone System*, W. A. Jackson and W. R. Cole, 310,282. *Combined Spring-jack and Annunciator*, L. Townsend, and R. W. Moore, 310,749, Jan. 13; L. Townsend, 310,750.

Telegraphs:—*Means for Overcoming Static Disturbances*, C. Selden, 309,571, 309,572, Dec. 23; F. W. Jones, 310,684, Jan. 13. *Quadruplex*, C. Selden, 309,573, Dec. 23; F. W. Jones, 310,685, Jan. 13. *Autographic Reed Telegraph*, B. A. Brooks, 309,600. *Means for Preventing False Signals on Reversals in Quadruplex*, H. Van Hoevenbergh, 309,751. *Printing Telegraph*, G. M. Hathaway, 310,587, Jan. 13.

Expired Patents:—A list of the more important electrical patents which expire during the current month is subjoined:—E. S. Ritchie, *Holtz Electrical Machine*, 74,139 Feb. 4; D. Munson, *Lighting Rod*, 74,402, Feb. 11; W. N. McInnis, *Spring for Relay Magnets*, 74,925, Feb. 25.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, *115 Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

NEW YORK, MARCH, 1885.

DEFECTS IN LETTERS-PATENT.

THE result of the litigation between the Gold & Stock Telegraph Company and the Commercial Telegram Company which was decided in the United States Circuit Court a few weeks since, is not without important lessons to intending patentees and purchasers of patents for valuable inventions. The history of the case is briefly this :—In 1868, Edward A. Calahan was granted a patent for a printing telegraph instrument which has since become well-known as the "Calahan three-wire stock-printer." The invention was simple, in fact almost crude, in its conception. It contained two type-wheels rotating side by side in parallel planes, one of which was provided with type for printing the letters of the alphabet and the other for printing numerals and such fractional signs as were useful for the purpose for which the instrument was intended. Each of these type-wheels advanced independently by a step-by-step motion communicated by an electro-magnet, ratchet and pawl. A third electro-magnet effected the impression by forcing a strip of paper simultaneously against the peripheries of both type-wheels. It is obvious that under this arrangement the letters were printed in one line and the figures and fractions in another. A letter upon one wheel and a numeral upon the other could be simultaneously imprinted, or a character upon either wheel separately by presenting a blank space opposite to it upon the other wheel. In the use to which the machine was actually applied, that of printing stock quotations, the capacity to print jointly was useless, the only necessary mode of operation being to print the title of the stock in letters with one wheel and then to follow it with the price printed in numerals from the other wheel. It was also found in practice that this mode of printing the record in two lines was in itself advantageous, because it was more quickly and easily read.

The Gold & Stock Telegraph Company was organized in 1867 on the basis of this invention, and eventually became one of the most profitable telegraphic enterprises in the country. The Calahan patent has always been esteemed as one of its most valuable possessions. Two years ago a competing system was established by the Commercial Telegram Company, making use of an instrument which printed a record in two lines exactly resembling that of the Calahan instrument, and which, while it had the like capacity to print separately in either two lines, did not have the capacity to print simultaneously in both lines.

The Gold & Stock Telegraph Company thereupon applied for a preliminary injunction against the Commercial Company, alleging an infringement of one claim of the Calahan patent, viz.:—

> Two or more type-wheels moving independently and controlled by magnetism, and arranged so as to print jointly or separately upon one strip of paper in two or more lines, substantially as specified.

Upon the hearing, the learned counsel for the defendant contended that the meaning of this claim was doubtful and said in effect that no one could tell whether the patentee intended to embrace within his claim an apparatus of the described kind capable of either printing "jointly" or printing "separately" or whether he meant only to claim a machine capable of printing both jointly and separately. The machine of the patentee had the capacity to print both jointly and separately, while the defendant's machine could only print separately, hence under one construction of the claim the defendant's machine might infringe the patent, and under another construction it might not, and no one could tell from the face of the claim which was the right construction. The Court said, in effect, that the case turned on the proper construction of the word "jointly" and remarked that the defendant's affidavits showed that "it is really one upon which much learning, skill and time may be profitably employed and which is not of ready solution;" and therefore refused to grant the injunction. The only recourse now left to the complainants is a long and tedious litigation, by means of which, if successful, they may recover damages from the defendants, but cannot otherwise interfere with their operations.

If the solicitor who prepared the specification of Calahan's patent had worded the claim in such a manner as to be free from obscurity, and especially had he confined it to the novel and essential feature of the invention, the separate printing from independent type-wheels, it is probable that the Court would have felt no hesitation in granting an injunction.

It may be seen from this example how vast may be the interests depending upon a slight verbal ambiguity or an unskillful use of words in the claim of a patent. Few persons, other than lawyers and experts, have any conception how small a proportion of the whole number of patents in force are capable of affording adequate protection, in case of adverse litigation, to the inventions upon which they are based. But an insignificant fraction of the whole number of patents ever come before the courts for adjudication, yet a large proportion even of these prove to be defective in the essential point of protecting the real invention of the patentee. As a general rule it may be said if an invention is worth patenting at all, it is worth doing in the

Digitized by Google

best possible manner. This is especially true in respect to electrical inventions, for the reason that these, if valuable, usually pass into the hands of large incorporated companies, and it is seldom now-a-days that these companies purchase a patent without first submitting it to a skilled expert for a carefully considered opinion of its validity and scope. The price paid is usually governed far more by the strength of the patent than even by the commercial value of the invention ; in fact the value of an invention may be trifling while strategic advantages arising from the ownership of the patent may be of enormous value. In the instance which we have mentioned, it is safe to say that a different wording of the disputed claim would have been worth some hundreds of thousands of dollars to the owners of the patent, if it could have been effected.

These considerations have now become more important than ever, in view of the position which has been taken by the Supreme Court in refusing to allow the enlargement of the claims of a patent by reissue. The defects in a patent are not usually discovered until an infringer appears, and it is seldom that this happens until it is too late to reform the original patent, so that the inventor often finds too late that the fortune which might have been his, has slipped from his grasp, owing to some trifling defect in the preparation of his patent papers.

ELECTRICAL RIGHTS OF WAY.

One of the most noticeable peculiarities of the telegraphic business is, that although it has been one of the most important and indispensable factors of civilization for over 40 years, its legal status in some respects has not yet, by any means, been positively defined. During this period not only has the original field of electric service been fully developed, but it has branched out in various directions, until at the present day the popular mind believes it, by reason of its wonderful adaptability as a servant of mankind, to be capable of fulfilling almost any desired mission. Yet, in spite of all its boasted progress, the telegraph system of to-day is to a great extent a sort of parasite, pursuing the business of conveying intelligence between different parts of the country by hanging on to the skirts of other organizations, without in itself being possessed of any actual right of way, except, as it were, by sufferance, over the innumerable routes which it covers. The authority of Congress in granting it the privilege of building along post-roads is disputed by states, municipalities and hamlets as an unconstitutional usurpation of power by the national government. The contracts by which the privilege of occupying railway lands has been permitted by their owners, have been attacked as being exclusive, and opposed to the public welfare. The advantages of railway routes for electric lines are now so generally recognized, that the difficulties in obtaining them have been among the many other obstacles to be met and overcome by the projectors of new companies. The avoidance of the multitudinous shade trees along the public highways, has rendered necessary the choice of three evils: a zig-zag line, the mutilation of branches, or the bodily removal of the trees. The occasional "trimming out" process which every turnpike line must occasionally undergo in order to keep the wires working at all, has without doubt been the primary cause of the opposition encountered in late years in securing street privileges in rural districts. Wherever telegraph wires may go, they are—and not without much reason—regarded as an unmitigated nuisance, excepting possibly in the wilds of Hungary, where it is asserted that they serve a useful purpose in protecting the inhabitants from the ravages of wolves, inasmuch as these animals are said to abstain from prowling in their vicinage.

The multiplicity of wires now in existence and their great prospective increase, has led us to the conviction that it will eventually become necessary for their owners to secure, under proper legislative authority, an exclusive right of way for telegraphic purposes by condemnation or purchase, the same as in the case of turnpikes, canals, railways and other public works. Upon land belonging in fee-simple to themselves, with no apprehension of being disturbed, a more substantial system of construction would be adopted, which would render communication absolutely certain at all times. This may be thought by some to be a Utopian view of telegraph construction as it should be, for the facts of telegraphic history have imbued us with the idea that its ways must of necessity be ways of short-sighted economy, and that its future must forever be hampered with questions of economy, competition, adverse legislation, bankruptcy and eventual government absorption.

The cost of a strip of land, say two rods wide, between New York and Boston for example, would not by any means be so great as to be prohibitory. The route might avoid the more thickly settled portions of the country, so that very little land of much value need be taken, while the entrance into cities and large towns could be effected by short sections of underground line or in any other convenient manner. A solid and substantial structure capable of sustaining many hundred wires might be placed upon such a right of way as this, where they would be free from the interference of trees and from the smoking of the insulators by railway engines. Under these conditions, we have no doubt that not only would the wires work far better than they do now, but that the cost of maintenance per mile of wire would be materially diminished. We should very much like to see some telegraph or telephone company whose managers had sufficient confidence in the permanency of the institution to undertake to do this. We have no doubt that it will be done by somebody, perhaps at no very distant day.

THE LIGHTING OF DEEP MINES.

There are perhaps no locations where artificial illumination is at once so important, and the problem of its satisfactory application so difficult of solution as in subterranean mining. In the case of coal mines, the ever present element of danger from explosions adds to the complexity of the conditions, and there has practically been no progress in the direction of the protection of life and property from these frightful accidents since the invention of the well-known safety-lamp by Sir Humphrey Davy seventy years ago. This device, although assuring the safety of the miner, when properly guarded, cannot be considered a satisfactory method of illumination. So defective has it proved in this respect in fact that miners frequently assume the risk of using a naked flame in order that a more powerful light may be obtained in particular cases. It appears that in practice the miner is beset with danger in either direction. A better light is required to enable him to examine the condition of the roof and its

Digitized by Google

supports. Indeed, the danger from the fall of face coal or the walls is more imminent, and correspondingly more dreaded than the explosion of fire-damp, the presence of which may frequently be detected by the sense of smell. Although the liability of damage to property is great, the usual policy prevails among mine-owners of preferring to incur the risk of possible loss rather than submit to the certain although smaller expense of adopting preventive measures. While the use of electric lights has been suggested, much doubt has been expressed as to their perfect adaptability to the winding galleries and isolated chambers of our anthracite mines. Of course there is comparatively little difficulty in lighting an open mine, and an installation of this character has been in successful operation at the Mechernich mines in Rhenish Prussia for more than three years.

The satisfactory result in the open workings induced the company to introduce the system in the subterranean galleries. Here the danger which is always threatened by the falling of loosened pieces of rock demands thorough illumination of the interior. Pitch torches were formerly employed for examining the bore-holes and adjoining fissures after each explosion. The smoky atmosphere rendered the success of the arc lamp somewhat doubtful. In the first experiments lamps of 1,000 and 3,000 c. p. were used, with the positive carbon in the lower holder. While the effect was brilliant, yet the rays did not penetrate the white smoke cloud which collects immediately after the firing of a blast, but as the smoke settles in a few moments, it was thought advisable to suffer this slight interruption and use smaller lamps of 350 c. p., which proved efficient. Ten of these have since been in use, with about 10,000 feet of lead cable, which, by reason of its pliability, allows the positions of the lamps to be changed. The progress already made in this direction leads to the belief that the thorough illumination of mines may be accomplished through the agency of electricity, by the use of existing appliances already familiar to electrical engineers. It is by no means necessary that lights should be so numerous as to flood the galleries throughout their devious ramifications. Circuits could easily be so arranged that incandescent lamps might readily be attached or displaced as required. The use of the arc lamp would of course be inadmissible in mines subject to fire-damp. While admitting that there are various obstacles to be overcome in such installations, we are confident that there can be none which will not give way to the personal application of that ingenuity which has already won so many triumphs in more familiar fields. Not that it is necessary that our great inventors should devote their attention to this work, but that responsible companies should be induced to undertake such installations, and that practical men with varied experience be thus brought face to face with existing difficulties, and be allowed all requisite facilities for removing some of the most imminent dangers now attendant upon our mining industries.

DEATH OF LUTHER G. TILLOTSON.

Few names have been more closely identified with electrical interests in this country than that of Luther G. Tillotson, who died at his home in this city on January 31st. He was born at Ithaca, N. Y., March 1st, 1834, and after receiving a common school education began his business career in 1849, as an operator upon the line of the Erie and Lake Michigan Telegraph Co., of which his father, the late Daniel T. Tillotson, was then Secretary and Superintendent. His progress was rapid, and his ability was so well appreciated, that at the early age of 19 he was appointed superintendent of telegraph on the Erie railway, a position in which he subsequently won distinction as the pioneer of telegraphic train despatching as since developed into a distinct and important branch of railway organization and management. His advanced ideas on this subject were a characteristic manifestation of that foresight, decision and promptness of action which have distinguished his subsequent career. After nine years service with the Erie company, he became impressed with the idea that the future growth of the telegraph would create an important field for merchandising, and in order to avail himself of such a business opening, he resigned the superintendency of the Erie line, and established himself in New York city in 1862 as a dealer in telegraph and railroad supplies, occupying a small part of a Broadway store. His almost immediate success in this enterprise confirmed the correctness of his views, and on the 1st of November 1865 the firm was reorganized under its present title of L. G. Tillotson & Co., General E. S. Greeley and Mr. W. H. Holt being admitted as partners. Mr. Holt retired in 1866, since which time the membership has been limited to Messrs. Tillotson and Greeley.

The business policy of Mr. Tillotson, while eminently a progressive one, was nevertheless cautious. It was his aim not merely to keep thoroughly abreast of the march of improvement, but to establish the reputation of his house as a place where everything could be obtained which could possibly be required in the operation of a railroad or a telegraph in any part of the world from which orders might reach him. Men who were located outside the pale of civilization might order a suit of clothes as well as a cell of battery with entire confidence that the order would be faithfully executed, while upon at least one occasion a superintendent was called for. Such was the excellent judgment of Mr. Tillotson that his selection of a proper man for a position of that kind might well be implicitly relied upon.

Notwithstanding the fact that his guiding hand was felt to be ever at the helm, he did not by any means confine himself to the actual business treadmill. He traveled extensively in pursuit of rest and recreation, thus wisely compelling his associates and subordinates to become thoroughly familiar with every detail of his establishment, so that now, although he has gone out from among them forever, the house of L. G. Tillotson & Co. will long bear upon its character the lasting impression moulded by its lamented founder.

Personally, Mr. Tillotson was one of the most pleasant, genial and liberal of men, although his physiognomy indicated that firmness could, when occasion demanded it, develop into that resolute sternness, so essential to proper discipline in those executive positions which he had filled with such distinguished ability.

Although brought into association with the promoters of many important enterprises, he did not distract his energy by becoming actively identified with them, as he might easily have done. He was at one time a director in the American District Telegraph Co., but beyond this has not been prominently identified with any corporation.

In 1857 he married Miss Emma A. Glenn who survives him, but their only child died in infancy. He leaves an ample fortune, and by his request the firm name of L. G. Tillotson & Co. will be retained; a fitting memorial of the useful and busy life now ended.

THE CONSTRUCTION OF LINES FOR ELECTRIC CIRCUITS.

BY THOMAS D. LOCKWOOD.

(Continued from page 45.)

THE clothes-pin attachment, like most great conceptions, is exposed to the fate of being anticipated. Hon. Amos Kendall, the early agent of Morse, was, before 1850, delivered of the following remarkable system of insulation which we give in his own words: "I think the following the cheapest mode of insulation yet devised, and as effectual as any: With a wide set saw, or otherwise, make a gap in the post downwards, at an angle of 45°, wide enough to receive the wire with its covering. Just cover the wire with the best india-rubber cloth, or a composition of which india-rubber is the chief ingredient, so far that the covering shall extend about 2 inches from the post on each side. Over that, wrap sheet-lead or tinfoil, not, however, extending more than an inch on each side of the post. Sink the wire so covered into the gap on the post, then pass large twine turned around the lead covering on each side of the post, and tie it tight round the side of the post opposite to the gap. It will have the double effect of confining the lead and turning off the water." Happily for the memory of Mr. Kendall he never tried this alleged insulator.

Another brilliant idea is embodied in the "pictur" below. It was first introduced into civilized society by an article in the New York *Electrical Review*, based upon a letter from Aguascalientes, Mexico, which states that the Zacatecas state telegraph lines use these apologies almost exclusively. The attachment itself, as clearly shown in the figure, is a piece of horn, with tip and butt sawn off, and a notch cut in the top. It is, of course, hollow, and surrounds the top of the bracket to which it is screwed. The line wire is passed through the notch and held there, by being fastened with a piece of No. 14 wire. The letter describing this remarkable appliance naïvely states that "these horn insulators, although poor insulators for telegraph, *are splendid anti-induction insulators for telephonic use.*" This statement lets the cat out of the bag. The horn insulators are poor for telegraphic purposes, because they are not insulators at all. Horn is not very much of an insulator at best, having about the same specific resistance as the hard skin of the hand of a laborer, and whatever insulation it possesses is lost by the method of fastening the wire. It is because of this non-insulating character that it will answer in a dry country for telephonic purposes, affording just sufficient leakage to keep the line clear of static induction. It is, however, probable that if the horn was dispensed with altogether, and the wire fastened directly to the bracket or pin, it would work just as well in dry weather. In wet weather, it is not likely that either wood or horn would prove eminently satisfactory, even for telephonic service.

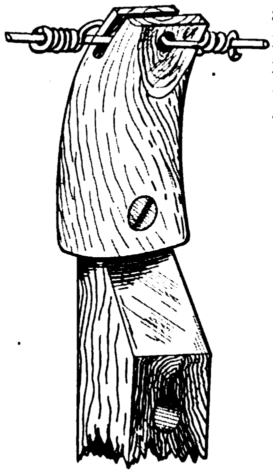

FIGURE 6.

It is a pleasure to look away from these oddities, to an invention in insulators which possesses real merit, and which, when better known, will be extensively employed. I refer to the form of insulator shown in figure 7.

A glance will show the nature of the improvement. In addition to the regular internal screw thread with which the insulator is as usual attached to the pin, there is an external screw on the apex of the insulator, but oppositely wound. That is, if the internal screw is right-handed, the external one is left-handed and *vice versa.*

The line-wire instead of being bound to the insulator with a tie-wire, is fastened with a special clip which is shown detached, in figure 8.

The object in providing the right and left-handed screws, is so that the wire can be fastened to the insulator, and the insulator screwed down on the pin by one and the same operation.

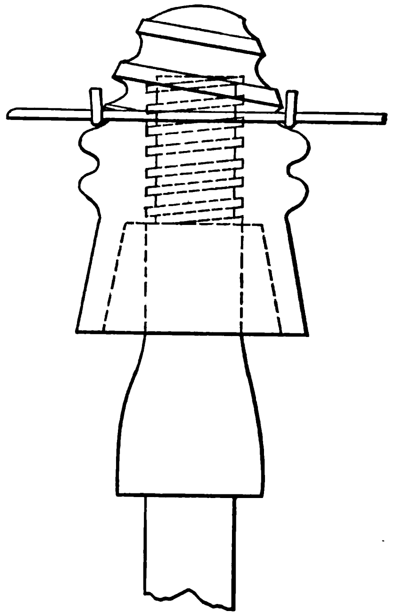

FIGURE 7.

In attaching the wire, the insulator is placed on the pin and given a couple of turns down. The clip is hooked on the line-wire with the ends of the hooks turned upwards. The loop thus formed is then slipped over the top of the insulator, and (care being taken to see that the clip goes down the thread of the screw first with the line-wire following) the insulator grasped by the hand, is screwed down on the pin as far as it will go, the outside screw at the same time insinuating itself into the loop of the line-wire and clip. These instructions for attachment, are by no means intended to serve as iron-clad rules to be observed, but an intelligent lineman observing the intention of the improvement, will readily adapt himself to it, and act according to the different conditions of each case. Even if insulators of this character are employed, circumstances may of course arise in which it will be found desirable to use the old mode of attachment. The insulator as now made, is provided with the ordinary circular groove, upon which the line-wire rests, for attachment with the old time tie-wire.

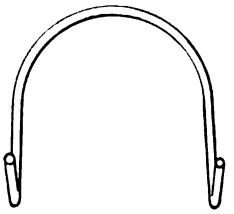

FIGURE 8.

It is, perhaps, unnecessary to recapitulate the advantages which are secured by the use of this form. It is well-known that a concomitant trouble of the old form of attachment was that scales of the zinc coating were sure to be rubbed off, thus leaving spots of unprotected iron wire at which oxidation would promptly commence. The leakage at each insulator may also be reasonably expected to suffer diminution, as the points of contact are lessened; while the line-wire suffers much less mechanical strain. It is also claimed that much time is saved in construction by its use, and it is evident that a single clip may be used many times, and that if it becomes necessary to detach the line-wire at any time, a few backward turns of the screw is the only operation necessary. Practical linemen whose opinion I have asked on this subject, concur in praising it highly and advocate its use, and it would therefore seem

Digitized by Google

that one of the greatest obstructions which threaten innovations, *i. e.*, the opposition of workmen, will not retard the introduction of this insulator.

The application of the external or wire attaching screw, is the invention of an Englishman, J. Slater Lewis, and has been patented in the United States. The happy conception of forming the outside screw of opposite direction to the internal or pin screw, so as to provide for the simultaneous attachment of both line-wire and insulator is, however, to be credited to Frank L. Pope, and is fully described in a patent issued to that gentleman, December 25th, 1883. Both patents have, for the entire country, passed into the hands of the National Insulator Company, of which Messrs. Loren N. Downs and H. B. Lytle, of Boston, are respectively President and General Manager, and J. W. Duxbury, of Providence, R. I., Treasurer. These gentlemen recognizing the practical merit of the combination, and having, moreover, control of other improvements in insulators, have established themselves in the Equitable Building in Boston, and will doubtless take pleasure in furnishing any additional information that may be required upon the subject.

SUPPORTS FOR AERIAL LINES.

These are of twofold character—poles set in the ground, and house-top fixtures fastened upon the roofs and walls of buildings. The habitual haste and hurry of this nation is fully exemplified in the way telegraph poles are treated, from the moment they are cut until they are finally discarded. In the early days of the American telegraph, lines were hurriedly built for fierce competition—poles were set immediately after they were cut, often while the sap was still running, and sometimes without even being barked. The result was a short life and by no means a merry one. This reminiscence is forced upon my mind by the way in which the sad history is even now repeating itself. The lines for the telephone were built much more rapidly than those of the early telegraph; sometimes by men who had been to school in telegraphic construction; more frequently by men who had served no such apprenticeship, and who had, as it were, to learn a completely new business. How should they know that poles should be cut at least six months before they were to be used? And if they did know, had they time to wait? Nor is it an easy matter to persuade these gentlemen that it is wise to paint all poles, or to char the bottoms. The ten cents present is usually a more potent consideration than the dollar to be saved hereafter.

But two materials for poles need be discussed—iron and wood, and the latter is used almost universally in American construction.

The kinds of timber used for this purpose are principally the red and white cedar; chestnut, redwood, cypress and juniper. Spruce and pine are used to some extent, but they are not to be recommended. Where it can be readily procured at a reasonable cost, the red cedar is for all practical purposes to be preferred. It is not a handsome wood to look at, but is very durable, and lasts longer than any other which has come under my observation. Chestnut is also very good, being tough, elastic and tenacious of life. The white cedar also makes a fair pole, but is more brittle and addicted somewhat to snapping off short, when it receives an unusual strain. Cypress and juniper are much used in the south, but the latter seems to be preferable; inasmuch as cypress in a moist, warm climate is easily attacked by dry rot, which materially shortens its life. Juniper is a rather coarse grained wood, but is said to be very strong and durable.

All poles should be cut in late autumn or winter, when the sap ceases to rise. Careful estimates show that this precaution adds some years to the life of a pole.

A report furnished by the Western Union Telegraph Co. to the Superintendent of the United States census and published in 1882, show the average length of poles to be 27 feet, diameter across the top, 6 inches; average cost of each pole, not counting freight, $1.02; and the further statement was made, that the average life of a pole according to the wood used, and the location, was from 12 to 15 years, and in no case exceeded 25 years.

After cutting, they should be trimmed, stripped of their bark, shaved smooth, and then stacked for 5 or 6 months in such a way that the air may freely circulate between them, the lowest tier of the stack being raised a few inches from the ground.

POLE PRESERVING PROCESSES.

Wooden poles have been found to suffer severely from both dry and wet rot, but especially from the latter. They are particularly subject to decay at the ground line. To counteract these destructive agencies, the English constructors have from time to time adopted various preservative processes, applying them to poles before setting them up. These have been of two kinds:

First,—The impregnation of the poles with a strong solution of some metal salt, which salt combining chemically with the vegetable juices, produces compounds unfavorable to decay.

Second,—To impregnate the poles thoroughly with creosote.

It is not necessary to describe the former processes, since it is most unlikely that any of them will be adopted by American constructors.

Creosoting is accomplished by placing the poles in an iron receiver, exhausting the air from them and then forcing boiling creosote into them under pressure. This process has always given such eminent satisfaction that in the future when our timber is less plentiful than at present it will possibly be adopted. It has not, in the United States, as yet been thought desirable to employ any of these processes, as our supply of timber is yet large, and it is also thought that American timber is of a more durable character than that of Europe.

The statement is made that unprepared American timber will last as long as the prepared European poles; but an exception must be made in favor of those prepared with creosote. One protective process invariably used in England, we might, I think, profitably import, particularly as it is neither complicated nor expensive; that is the practice of roasting the butt end of poles in a slow fire until they are well blackened, for about 5 or 6 feet up, before setting them (care being taken not to burn them), and then tarring the blackened part and bottom with a mixture of coal and wood tar, and slacked lime. This compound operation prevents moisture from entering the buried part of the pole.

(*To be continued.*)

APPLICATION OF ELECTRICITY TO HOROLOGY.

BY CHARLES A. TERRY.

I.

One of the earliest and most obvious methods of determining the time of day, is that of noting the position of the sun by the length and position of the shadow cast by an opaque object, and probably the earliest artificial device constructed for the express purpose of measuring and indicating the passage of time was one depending solely upon this method, namely, the well-known sun-dial. The usefulness of this instrument depended, however, too much upon fair weather and a clear sky to render it of any great service, especially in such a climate as that of England. Graduated candles and sand-clocks or hour-glasses were accordingly resorted to for measuring time throughout the day and night, though these could hardly be relied upon as reasonably accurate time-keepers for any considerable periods. The first step toward the production of a mechanical time-piece, which would indicate the hour correctly from day to day, is found in the water-

Digitized by Google

clocks used by the Greeks and Romans, but even these were very far from being reliable and regular in their operation.

The appearance then of the mechanical clocks "impelled by weights and wheels, so that they pointed out the hour, day and night with certainty" was an event of an import which all men must have appreciated. It is probable that such clocks were made during the latter part of the eleventh or early in the twelfth century. For nearly eight hundred years the human mind has been constantly at work developing, improving and perfecting the mechanical time-piece. At first thought it would seem that nearly everything that could be desired must be performed by the ingeniously constructed clocks of the present day, and yet as a matter of fact one is never surprised at finding a number of different clocks indicating as many different times. The ornamental clock upon the mantel usually varies from the tower-clock, and it is often the case that neither indicates the true time, while in any event it is necessary to correct them frequently to make them agree with some recognized standard chronometer or time-ball. Evidently, therefore, mechanical clocks have not in all these centuries been so far perfected that they can as a rule be depended upon to keep uniform time. Again, while it is true the advent of the mechanical clock removed the necessity of turning the hour-glass and filling the water-clock, yet it is no less true that even the labor of winding the spring or weight of the mechanical clock becomes irksome from constant repetition.

Two desirable results are therefore still to be attained in the construction of mechanical clocks, namely, accuracy and self-operativeness. It has been the especial aim of the inventors of electrical clocks to meet both these requirements, and it is proposed in this article to present a brief account of the first application of electricity to clock-movements and dials. In a consecutive article we will consider more in detail the subsequent improvements, the development of a complete electric-clock system, together with certain special forms of electric clocks of comparatively recent invention.

Soon after the first appearance of electric clocks, which was in 1840 or 1841, a considerable controversy arose as to whom belonged the honor of being the first inventor. The principal conflicting claimants were Alexander Bain and Professor Charles Wheatstone. Professors Daniell, Moseley and Willis, Dr. Arnot and W. Snow Harris publicly certified that, in their opinion, Mr. Wheatstone's claims were well founded. Mr. Bain and his friend Mr. Barwise maintained, on the other hand, that they were the exclusive proprietors of the disputed invention, both by right of conscience and also by royal license (they having obtained a patent), and that Professor Wheatstone had falsely and ungenerously sought to arrogate to himself discoveries and inventions of this character to which he had not the smallest rightful claim. It appears that the claim of Professor Wheatstone had for some two years, owing largely to his social position and the high standing of his professional and scientific friends, received general acceptance. In 1843, however, a new advocate of the claims of Mr. Bain appeared in the person of John Finlaison, the Actuary of the National Debt office. Mr. Finlaison published a pamphlet entitled "An Account of Some Remarkable Applications of the Electric Fluid to the Useful Arts by Alexander Bain, with a Vindication of His Claim to be the First Inventor of the Electro-Magnetic Printing Telegraph and also the Electro-Magnetic Clock." In commenting upon this pamphlet the editors of the *Mechanics Magazine*[1] writes as follows:

Mr. Finlaison is "a gentleman of great eminence in a most difficult branch of study, enjoying deservedly the confidence of Government and the public, and distinguished beyond most men for habits of patient enquiry and independent judgment. After a most acute and searching investigation of the several claims to the invention of the Electro-Magnetic Clock and Electro-Magnetic Printing Telegraph he determined the question in favor of Mr. Bain and his friends, Messrs. Barwise and Wright." The one great and important conclusion at which he arrives is "that Mr. Bain is the true man and Mr. Wheatstone (so far as regards the inventions in question) the pretender. For our own parts we adopt this conclusion of Mr. Finlaison's with great pain, holding in very high esteem Mr. Wheatstone's unquestioned and unquestionable merits in many other respects; but at the same time without hesitation; for it is a conclusion irresistably forced upon us, by an attentive, dispassionate and wholly unbiased consideration of the facts and arguments adduced by Mr. Finlaison in its support."

Mr. Bain originally came from Caithness in the north of Scotland, and at the time when he conceived the idea of employing electricity as a moving power for clocks and time-pieces, he was in the employ of John Barwise, an eminent London chronometer maker in St. Martin's Lane. In the pamphlet referred to, Mr. Finlaison says of him: Bain is a self-taught genius, kind-hearted, sober, temperate, candid, incapable of deceit, and utterly free of guile; but considering his years and opportunities well versed also in electrical science. Add to this that in practical mechanics he is not merely an artist of the very first order (an immense advantage this over the man of books, because his hand can execute whatever his mind conceives), but he is endowed moreover with inventive faculties of such fertility that no one can see the exercise of his ingenuity without wondering what new invention may next occur to his prolific imagination."[2]

As early as 1840, Mr. Bain proposed to operate a number of clocks simultaneously, to wind the going and the striking train, to correct the minute-hand from any slight deviation at predetermined intervals, and in fact, to perform nearly all the diverse operations which it has been the endeavor of subsequent electricians to perfect.

Early in 1841, a patent was granted in England to Barwise and Bain for improvements in the application of moving-power, to clocks and time-pieces. They proposed to construct a self-operating clock by securing to the pendulum of a mechanical clock an armature which was to be periodically acted upon by an electro-magnet, the electro-magnet being included in a circuit periodically closed by a sliding rod worked by the pendulum itself. The pendulum also carried a catch-spring which served to drive the clock-train. This device has been reinvented by innumerable later aspirants, but the successful and satisfactory operation of such a clock may well be doubted. A more important part of the invention is that relating to the operation of secondary clocks or dials. Two different plans for effecting this were proposed. The one consisted in completing an electric circuit successively through various conductors leading to as many secondary clocks. This was accomplished by causing a contact-spring, moving with the 'scape-wheel of an ordinary clock, to pass

1. Vol. 39, p. 64, July 22, 1843.

2. Alexander Bain was a native of Thurso, North Scotland, where he was born in 1811. He learned the clock and watchmaking trade and came to London in 1837 with the intention of following that business. While attending a lecture on electricity, soon after his arrival, his ingenious and fertile mind conceived the idea of applying electricity to clocks, which, in turn, led to the invention of a new form of electric telegraph. By the summer of 1840, he had completed models of both these inventions, which he showed to Mr. Baddeley of the *Mechanics Magazine*, who referred him to Professor Wheatstone. The latter interested himself in the invention, but the circumstance led to an unfortunate controversy, not altogether creditable to him. Bain patented in rapid succession his electric clock (1841), printing telegraph (1841), autographic telegraph (1843), fire alarm telegraph (1845), electric thermostat (1845), electric ship's log (1845), and electro-chemical automatic telegraph (1846). In 1848, Bain came to the United States to patent and introduce his telegraphic system and was taken up by Henry O'Reilly who was then engaged in a bitter contest with the owners of the Morse patent. He assisted Bain in procuring his patent, and lines were built all over the country on which the Bain instruments were employed. In 1852, after prolonged litigation, the Bain system was declared an infringement by the Circuit Court of Pennsylvania, although a few lines were in use up to 1860. Bain returned to England, and but little was afterwards heard of him as an inventor. He revisited America in 1863, but it was then evident that intemperance was rapidly undermining his bodily and mental powers. He died of paralysis in January, 1877, at an institution near Glasgow, of which he had been for some years an inmate. He was a man of striking personal appearance, of large frame, with a peculiarly massive head. His name will always be prominently associated with the history of electrical inventions. F. L. P.

across a series of contact-points inserted in a non-conducting disc. With a seconds-beating clock, 60 contacts might thus be made each minute, one for each beat of the pendulum, and as many different secondary clocks in this manner operated by the primary clock. A modification of this plan was to operate a number of clocks simultaneously, and this differed from the first in employing a battery of a greater number of elements and placing a series of clocks in a single conductor. The secondary clocks consisted merely of the requisite train, the 'scape-wheel of which was driven step-by-step by the movements of the armature of a corresponding electro-magnet.

The second plan was to alternately complete a circuit, by the operation of the primary clock, through two conductors including two electro-magnets. A single armature was applied to the two magnets and it was driven to-and-fro in unison with the movements of the circuit-closer of the primary clock. The movements of the armature were communicated to the secondary clock-work by driving pawls. For the purpose of driving a number of clocks in this manner, it was proposed to cause the movements of the first armature to complete the circuit for the next clock and so on through as many clocks as the duration of the contacts of the circuit-closer would permit.

The winding of a series of mechanical clocks was accomplished by automatically completing a circuit with each clock at a predetermined time, and this circuit remained complete for say a minute. The winding magnet of the clock was thus vitalized and its armature driven forward. The reactive pressure of a gun-lock spring caused a bar carrying driving pawls to be driven to-and-fro. The pawls engaged the teeth of ratchet wheels upon the main-spring axis of the going and of the striking trains and thus the clock was wound.

This patent of 1841, contains also a description of a device for setting the clocks to indicate correct time, in one instance by prongs engaging a pin moving with the minute-hand arbor, and another instance by means of an electro-magnet the armature of which moves two clips working upon pivots attached to the front plate of the clock. When the magnet is vitalized the clips grasp the minute-hand, provided it has not deviated more than a minute from the regulating clock, and set it in exact time therewith. This last feature has been extensively adopted in a modern system of synchronizing to which we shall have occasion to refer hereafter.

Although the name of Barwise is associated in this patent with that of Bain, the latter was doubtless the real originator of all the essential features of the invention.

Later in 1841, Bain in conjunction with Lieut. Thomas Wright was granted another patent for "certain applications of electricity to the controlling of railway trains, the giving of signals, printing telegraphs and the actuating of clocks," but the application to clocks was in this instance of minor importance.

About 1843, Mr. Bain constructed an electric clock which was operated by currents derived from two plates, a zinc and a copper or a carbon plate, buried in the earth. These plates constituted an earth battery. Upon the pendulum bob there was placed a helix of insulated wire, and confronting this upon opposite sides were placed permanent magnets. A circuit controlling device completes the connection of the earth battery through the helix when the pendulum is near one limit of its vibration and interrupts the same when near the other limit. The helix when thus in circuit is attracted by one magnet and repelled by the other. Upon the interruption of the current the pendulum oscillates in the opposite direction.

Figure 1 illustrates such an organization. The two earth-battery plates are represented at M and N, and these are periodically connected with each other through a conductor L by the operation of the pendulum. The pendulum rod *a* is suspended by a spring a^1 and at its lower end there is carried a coil C of insulated wire. This coil is intended to vibrate between the poles of permanent magnets N S. These magnets have opposite poles confronting each other so that when a current of electricity tra-

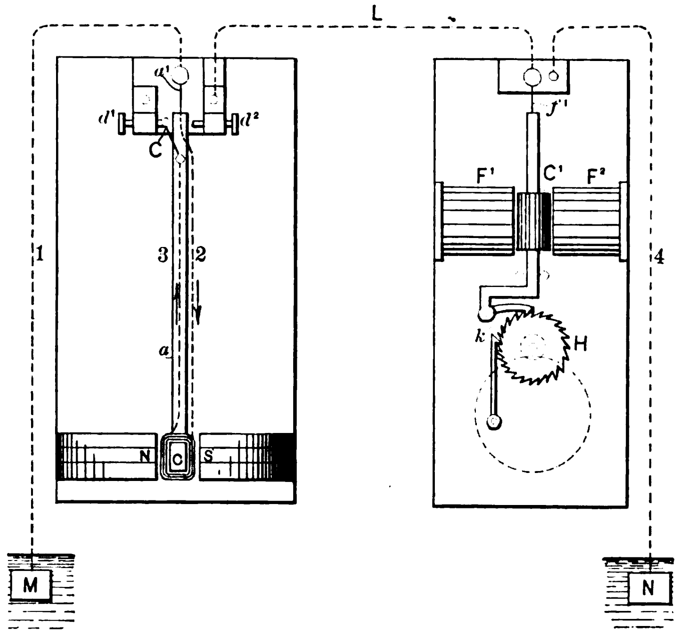

FIGURE 1.

verses the same from the earth-battery the coil will be impelled, in this instance, toward the right hand, both by reason of the repulsion exerted by the poles upon the left hand and the attraction of the poles upon the right hand. For the purpose of completing and interrupting the circuit, a small metallic ball *c* is pivoted to the pendulum rod, in such a manner that it is free to vibrate from side to side. Two insulated contact-stops d^1 and d^2 are supplied to the ball. When the pendulum swings to the left the ball will fall against the stop d^2, and when it swings to the right it will fall against the stop d^1. A conductor 1, leads from the plate M to the suspension spring a^1, and this spring is connected through an insulated conductor 2 with the coil C, and through this coil by a conductor 3 with the contact ball *c*. The conductor L leads from the contact-stop d^2 to a secondary movement. This consists of a coil of insulated wire C^1 placed axially between two confronting compound permanent magnets F^1 and F^2. The coil is suspended by two insulated springs, one only appearing in the figure at f^1.

The two springs are connected with each other through the coil C^1. The line L leads to one of the springs, while the other is connected by a conductor, 4, with the earth plate N. When, therefore, the battery circuit is completed by the movement of the pendulum *a*, a current will be transmitted through the coil C^1, and this will be impelled from one magnet between the poles of the other. Upon the interruption of the current the tension of the springs combine with the force of gravity to swing the coil in the opposite direction. A driving pawl, *h*, is caused by the to-and-fro movements of the coil C^1 to advance a wheel, H, and to thus actuate a clock train.

The compound magnets which appear in this instance each consists of a cylindrical series of permanent magnets surrounding a central core, and the coil, when it swings, passes outside the latter and within the circle of the poles of the former.

Such a clock Mr. Bain constructed and placed in the house of Mr. Finlaison in 1844. It contained but three small wheels, and, of course, required no spring or weight, being impelled by the currents derived in the manner stated. It is reported to have kept perfect time.

Another of these clocks, which Mr. Bain placed at his manufactory, was constructed to extinguish the light which

Digitized by Google

illuminated the dial, at a predetermined time. The clocks of this description were usually enclosed in an oak case about 4½ feet high and 16 inches wide. They were furnished with second, minute and hour hands.

In a patent taken out by Mr. Bain this same year (1843) several different methods of operating clocks upon this principle, by currents derived from earth batteries are described, and the clocks which he introduced into public use appear to have been, for the most part, constructed in accordance with the description contained in this patent. A contemporary writer, John Gray, refers to these clocks as follows:

"When Mr. Bain, the patentee, first introduced this wonderful invention into the city of Edinburgh, I at once gave him an order for an electric clock with instructions to make me, if possible, a particularly good one. The accuracy of its time-keeping qualities may be judged by the fact that it goes correctly within about five minutes a year; that from the 9th of January to the 15th of February during the present year (1843) it has neither gained or lost a single second."

In 1845, Mr. Bain proposed to render a clock self-operative by causing a slight impulse to be repeatedly given to the pendulum. The movements of the pendulum control the circuit-connections of an electro-magnet and the armature-lever of the magnet controls an impulse-lever which is employed for giving the maintaining impulses to the pendulum. In a patent granted to Mr. Bain in 1845, the clocks are described as being so constructed that the current will be automatically interrupted when the vibrations of the pendulum have increased beyond a prescribed limit. The current is then practically withheld until the vibrations are reduced to the required standard.

Mr. Bain's attention being directed at this time more particularly to his electro-telegraphic inventions he did not find time to introduce his clocks into extensive public use although he always regarded the invention as a valuable one, and those clocks which he did put into use gave great satisfaction.

After about 6 years of practical work in manufacturing and testing electrical clocks, Mr. Bain endeavored to operate the clocks by means of permanently magnetized balance-wheels. Such wheels were driven to and fro by alternating currents transmitted through hollow coils of insulated wire within which the balance-wheel passed. The system is very similar to one proposed by other inventors in connection with vibrating pendulums many years later. The same idea was also applied by him to the winding of clocks constructed with springs or weights.

Mr. Bain evidently fully realized the desirability of providing some means for periodically setting all clocks, whether electrical or mechanical, that they might indicate correct time uniformly, for in 1847 he had developed no less than 3 entirely new and distinct methods of "setting to time, clocks and time-keepers." The first consisted of a simple device acting upon the minute-hand and operated by the action of an electro-magnet. The necessary electric current was derived from a thermo-electric pile acted upon, at a particular moment, by the rays of the sun passing through a slotted plate or through a lens. In this ingenious suggestion we find a recurrence to the principle of the sun dial as a means for obtaining correct time. In the second device a thermometrical circuit-closer, likewise acted upon by the sun's rays, was employed, and the third consisted of a rubber-ball released at the proper moment and a circuit-closer for operating the correcting device.

Mr. Bain's inventive genius was not by any means confined to the perfecting of electric clocks nor electric telegraphs, for during the years 1841–'47 he invented improvements in electric railway signals, telegraph line insulators, ship's logs, and musical instruments.

Several other inventors in the field of electric clocks appeared at about this time, and among them one or two Americans. The results of their labors we shall consider hereafter. (*To be continued.*)

INSTRUCTIONS FOR USING HARD-DRAWN COPPER WIRE.

Experience in the use of hard-drawn copper wire has demonstrated the fact that its durability is considerably lessened by the ordinary handling which galvanized iron wire receives in line construction. In order to avoid the damage arising from careless treatment the following instructions have been issued to linemen employed by the Baltimore & Ohio Telegraph Company:—

The hard-drawn copper wire used by this company, while possessing sufficient hardness and tenacity for its legitimate use, will not stand the rough handling to which iron wire may be subjected without injury. In order, therefore, that danger of bruising or marring it may be avoided, while in transit or being strung, the following directions must be complied with:

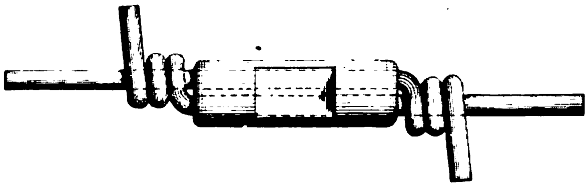
Every coil should be examined before the sacking is removed. In case the covering is frayed or torn, the coil should be closely inspected to see that it has not been cut or marred from the same cause that injured the sacking. In case the wire is found to have sustained injury, the coil must not be used unless the injured portion can be easily cut out.

Coils of copper wire should never be thrown from a moving train.

While unreeling the wire, great care must be taken to avoid twists and kinks. Whenever a kink is found it must be cut out, and a good splice made. This also applies to splits or indentation of any kind.

In tying the wire to the insulator, the wire should not be tied so as to touch the glass. The tie-wire should first be put entirely around the glass, one twist made in it, then the line-wire brought up and the two ends of the tie-wire twisted around it, with at least five turns, thus leaving the line-wire without bends or kinks. When done, the projecting ends must be twisted off, using the pinching portion of the Helvin grip for this purpose.

Care should be taken that the hard-drawn wire be not stretched as tightly as iron wire under like conditions, that it may not be broken by contraction in cold weather.



The Helvin Splice.

Hard-drawn copper wire must always be joined with the Helvin splice, whether in constructing new lines, or in repairing breaks upon finished wires. No excuse will be accepted for the use of any other splice. Linemen must always carry with them a plentiful supply of the couplings.

Splices must be made in strict accordance with the following directions.

Place the brass coupling in the "grip" or clamp, and secure it by means of the catch at the ends of the handles. Run the two ends of the wires to be spliced through the holes in the coupling, letting each project about five inches. Then, with the unemployed hand (pliers must not be used), wind each end closely around the wire as it enters the coupling, taking particular pains to see that the first turn is close to the coupling, that each turn fits closely to the straight wire, and that at least five turns are made. When this is done, put a little powdered rosin on the two wires where they enter the coupling at each end, still keeping the grip upon the splice. Then solder quickly with soft wire-solder. Finally, when cold, break off (do not cut) the projecting ends of the wires. Pliers, vises, or "holdfasts" must never be used on hard-drawn copper wire. Linemen found using them will be promptly dismissed.

THE PROBLEM OF THE ELECTRIC RAILWAY.

BY CHARLES G. CURTIS.

It would be very difficult for an outsider, not an electrician, to form any idea of the feasibility or probable economy of propelling the elevated railroad trains by electricity, unless he had given that subject and particular problem a great deal of attention and calculation, without being influenced by the "claims" of non-expert parties. The difficulty of forming a correct conclusion has been much increased by the fact that nearly all the public have heard on the subject, has been the occasional announcements of tests by independent parties, each of whom has declared its exclusive ability to propel cars by electricity, by reason of certain alleged improvements invented and said to have been patented by them, which made it practically possible, and also by reason of the fact that they own, or would own the only ground patent on the subject; when, as a matter of fact, there have been no such improvements made (of great consequence), no such controlling patents have issued, and the only "ground" patent is still in the Patent Office.

This patent was awarded to Mr. S. D. Field last summer, after a protracted litigation in the Patent Office with Mr. Edison and Dr. Siemens, and will shortly issue to Mr. Field, unless it is put in interference with a new applicant swearing thathe made the invention before Field did in 1879. It will cover,—if it can be sustained broadly, which is doubtful,—every electric railway in which the electric current is generated by a *stationary dynamo-electric generator* and conveyed to the moving car through the rails of the track over which it travels, or through other special conductors laid parallel to the track, with which the car makes a constant traveling connection. This is the only feasible way at present to propel cars by electricity, and is the plan on which it is proposed to run the elevated railway trains.

There has been the usual amount of assertion by certain parties claiming to have greatly improved electric railways, especially as regards the efficiency of the motors, the use of currents of low electromotive force, etc., and to own the only controlling patents on the subject, etc., without any discoverable foundation. Four or five years ago Mr. Edison built an electric railway at Menlo Park about two miles long, upon which many prople have since ridden, showing that it was perfectly possible and even economical to propel one or more trains upon the same track, the current dividing itself between the trains in multiple arc, precisely as the lamps are supplied in the *multiple arc system*, which has been so well developed by the Edison Electric Light Company. His generator was a first rate dynamo-machine, his motor another dynamo and therefore equally efficient, and except in mechanical construction of the track and locomotive, every electric railway built in this country since 1880 has been substantially the same thing, with only slight changes suggested at that time, which have not resulted in any material increase in the efficiency, and have not even been patented. The step from the present electric railways to a complete elevated railroad system as proposed, working uniformly and reliably is not a question of patents or improved motors, but of bringing to bear upon the problem the very best electrical and mechanical engineering talent available.

The advantage of electricity over steam that first suggests itself is the saving in coal, but of course its comparative importance cannot be realized without knowing the total cost of operating the roads. The coal saved is easily calculated by comparing the pounds of coal now consumed in the locomotives with what would be required to produce the same horse-power in stationary engines, and allowing for a proper loss in transmission. For this, we will not start with the much-quoted figures given by London *Engineering*, as the Elevated Railroad Co's. do not pay for their coal at that rate. It will be better to base the comparison upon the quantity of coal actually consumed by these locomotives. Each locomotive is officially stated to burn about 40 lbs. of coal per mile run, at a mean speed of 12.5 miles per hour, which is at the rate of 500 lbs. per hour. It moves an average load throughout the day of about 170,000 lbs. at this speed, equal to 1,100 feet per minute. Applying a coefficient traction of .004 (it would probably be a little less with such good rolling stock), this becomes 680 pounds moved 1,100 feet per minute, equal to 23 h. p., and costing 500 lbs. of coal per hour; or about 22 pounds an hour per h. p. This enormous figure includes everything, waste, reserve, switch engines, etc., and it also includes warming the trains, but the latter service could not amount throughout the year to more than one-tenth of the whole coal, and therefore to obtain the necessary power the company has at present to pay for at least 19 pounds of coal per h. p. hour. Large stationary engines can do it for 2.5 pounds, but the engines and boilers that will be used, will probably, as they always do in general practice, require about 3 pounds, including every waste, but certainly not more. Consequently, if no power were lost in the double conversion between the stationary engine and the driving wheels of the electric locomotives, the actual saving in fuel would be over five-sixths of what is now used. But as such a loss is of course unavoidable, the fuel question resolves itself into:—How much can the electric locomotives be expected to return of the original power put into the stationary generating dynamos? To answer this involves a clear understanding of how an electric motor operates efficiently to convert the current into mechanical work.

Every scientist now knows that a dynamo-electric machine is almost *perfectly efficient;* that is, it will convert from 90-95 per cent. of the power applied to it into electrical energy or current, only 10 per cent. being ever needfully lost. The reason of this is quite clear when we consider that the resistance the machine offers to rotation, which is what absorbs the driving power, is *due to* and *produced by* the current actually generated, and consequently is the equivalent of the current, less of course the loss of from 5-10 per cent. by friction, etc. In other words, if the dynamo, though running, is not generating any current (when the circuit is open, for example), it requires no power to drive it; if generating less than its full capacity, it requires proportionately less power. It is also well settled now, as many electricians had predicted, that the same dynamo-machine will work equally well as a motor; that is, re-convert the current passed through it into mechanical energy; and by combining two such machines it has been assumed that power may be transmitted electrically by turning it first into current and then back into power, with as little loss in the second conversion as in the first. Theoretically this is true, but in practice the same conditions which make electrical transmission most desirable, especially for long distances, also make it impracticable to get as good a result from the motor as from the dynamo; a certain amount of the current being necessarily *lost in heat* in the circuit; though the dynamo can always be made to yield at least 90 per cent. of the power expended upon it. How much this loss will amount to in any given case can only be found by knowing how an electric motor operates, and it would be very difficult, as the matter now stands, for any one unfamiliar with the subject to get at the true theory of its operation. It seems to be generally supposed, even among some of the most eminent electricians, that the loss in the conveying conductors, due to heat, depends only upon their resistance—that is, their resistance, as compared with the resistance in the motor and the dynamo, precisely as in an electric-lighting system—and that, therefore, to transmit power efficiently is only a question of size of conductors. As a matter of fact, large conductors are necessary in practice to carry much power, where currents of low pressure must be employed, but their size does not affect the *percentage* of current-energy in circuit reconverted into power by the electric motor. On the contrary, the efficiency of transmission has nothing to do with either the

Digitized by Google

resistance of the conductors or the particular kind of motor employed, but it depends entirely upon the *opposing* or *counter-electromotive* force set up by the motor when running; and this in turn is proportional to its superiority as a dynamo. There may be other points about a well-constructed motor which adapt it to particular conditions, such as lightness, shape, etc.; but as far as efficiency is concerned, it makes no difference how it is made, whether of an Edison type, or a Gramme type, or any other type. So long as it generates a counter E. M. F. equal to a certain fraction of the direct E. M. F., it necessarily has a converting efficiency represented by that fraction; and the best machine yet produced to "generate electro-motive force" (with the lowest speed, of course), is the best dynamo machine. For this reason the best dynamo machine "reversed" makes the best possible motor, and as the dynamo cannot be much improved in this respect, it is not very probable that the motor has been or will be—notwithstanding the extravagant assertions of certain inventors who have got many thousand dollars from capitalists on the strength of their statements to the contrary. When an electric motor is running, it necessarily, like an electrolytic couple or storage battery being charged, acts like a "reversed" dynamo, and tends to set up a more or less strong opposing current, called a *counter-electromotive force*, and it is the relative strength of this counter E. M. F., compared with the direct E. M. F. of the generating dynamo, that determines what fraction of the whole current in circuit is converted into work by the motor. If the counter E. M. F. be half the direct, the efficiency of the motor will be 50 per cent. If the counter be only 25 per cent. of the direct, the efficiency will be only 25 per cent.; if 75 per cent., the efficiency will be 75 per cent., and if the counter equal the direct, the efficiency will be 100 per cent. or perfect, which in practice is of course impossible. This is true, entirely irrespective of the *resistances* of either the dynamo, the conductors, or the motor. The generating dynamo machine, if ordinarily good, converts at least 90 per cent. of its driving power into circuit current. Of this 90 per cent. the fraction re-transformed into work by the motor is exactly equal to the ratio between the two electro-motive forces, if we deduct from this ratio losses in the motor aggregating at most 10 per cent. due to friction, Foucault currents, etc., which are equal to the corresponding losses of 10 per cent. in the dynamo. In fact, to ascertain the efficiency of any good motor, it is only necessary to measure these two electromotive forces by a galvanometer. These are all the losses that can possibly occur. Hence, with a counter of say 90 per cent., the net efficiency of the double conversion would be 90 per cent. of 90 per cent., or 81 per cent., less 10 per cent. loss in the motor, or about 73 per cent. In other words, the loss between the stationary engines and the track would be about 27 per cent. The very satisfactory efficiency of 73 per cent., and even more, could thus be had in practice, were it not for the fact that the counter E. M. F. reacts directly upon the generating dynamo. Its effect is just like that of so much extra resistance introduced into the circuit. It more or less neutralizes the direct E. M. F., causing the generator to produce just so much less electric current; but without affecting its efficiency, because at the same time the generator requires just so much less power to drive it. If the strength of the counter E. M. F. is carried too far, it is like interposing a very high resistance in circuit, the consequence being that the generator produces practically no current, and no power is transmitted. We know that if we double the resistance in a dynamo circuit, keeping its electromotive force constant, the dynamo generates only half as much energy in the form of current. In exactly the same way a counter E. M. F. of one-half in circuit reacts on the generating dynamo, causing it to generate only half as much current. Thus we see that increasing the counter E. M. F. results in two effects: first, it reduces the amount of current generated by the dynamo; and second, it causes the motor to convert a larger fraction of what remains into work. If the counter be low, the current is strong, but the motor's efficiency is low. On the other hand, if the counter be high, the current is low, but the motor's efficiency is high. The question then suggests itself whether these two things balance each other, or whether there is a certain relative counter E. M. F. which the motor will be giving out its maximum work (it being assumed that the direct E. M. F., being limited, remains constant). The fact is, that the motor will be doing its maximum work when the counter is half the direct, and it is interesting, as a matter of theory, to know why this is so, although in most actual cases a higher counter E. M. F. will probably be used. The work absorbed or the current developed by the generator we know to be equal to the direct E. M. F., multiplied by the current-strength; and the work done by the motor, as in electrolysis, to the counter E. M. F., multiplied by the current-strength. Since the current-strength falls as the counter E. M. F. rises, and *vice versa*, their product is greatest when each is half its maximum, or when the counter is 50 per cent. Hence a given system would be transmitting its maximum capacity when the motor is so worked that it generates a counter E. M. F., equal to 50 per cent. of the direct E. M. F. This fact is of no great importance in practice, however, for a higher counter will probably be employed, because the system will transmit almost as much power, while the efficiency is considerably raised. Besides this even with a counter of about 75 per cent. the dynamos would be giving as much current as they do in a light system, which is all they can carry, and with a counter as low as 50 per cent. the current would probably be strong enough to burn out or seriously overheat them.

The simplest way to estimate how high a counter E. M. F. will be economical in practice, is to compare the case with an incandescent light system. In a light system the current flowing through the conductors is controlled (mainly) by the lamps, and these are made of very high resistance compared with the rest of the circuit, in order that they may receive and turn into heat a large portion of the current in circuit. The Edison system, for example, is so proportioned that when all the lamps are turned on they form at least 80 per cent. of the total circuit-resistance, and they therefore utilize 80 per cent. of the whole current generated, the remaining 20 per cent. being lost as heat, mostly in the conductors. The reason for not making the conductors larger, so as to be of less resistance than 20 per cent. and thereby reduce the loss, is that the cost of the extra coal to sustain this loss is less than the interest on the increased cost of the larger copper conductors; on the other hand, if the conductors are made smaller and the loss exceeds 20 per cent., it is found that the extra power costs more than the increased interest on the copper conductors. Now, in a power system the motors take the place of the lamps, but as they are of very low resistance, they would draw an enormous current from the conductors, sufficient probably to burn out both motors and dynamos. This, however, is prevented by the counter electromotive force generated by the motors, which takes the place of the high resistance in the lamps, and regulates the supply of current exactly as does the lamp resistance in a light system. Consequently, in a well arranged system (as far as can be stated in general), with motors substituted for lights, the counter E. M. F. employed, together with the small resistance of the motors, should be the equivalent of the lamp resistance which it replaced, or a little less than 80 per cent. of the direct E. M. F., which would yield a net efficiency of about 65 per cent. Under these circumstances the dynamos would be giving the same current, and the motors would convert about the same current into power as the lamps were utilizing. Raising the counter above this point would cause the system to furnish less power, so that it would be necessary to increase the size of the plant. In any case, therefore, the efficiency of transmission must be offset by the size of motors, dynamos and conductors capable of delivering the

Digitized by Google

required power. In some cases (water power, for example) efficiency is of little consequence, and cost of plant is everything; while in others, where a large amount of power is to be conveyed, and the original power is costly, cost of plant is insignificant compared with cost of original power, and under such conditions a net efficiency of transmission of over 65 per cent. would probably be more economical than a lower efficiency with a less expensive plant.

All this applies to cases where the motor, being stationary, is kept running at a *practically* constant speed, and when this is so, there is no doubt that an efficiency of 65 per cent. can be obtained. But where the speed of the motor is continually varying, as it will probably have to do in locomotives on the elevated railroad, which part of the time are just starting or moving at less than full speed, the average counter E. M. F. will be considerably reduced. If the motor be mechanically belted or geared to the driving wheels at an unchangeable rate, its speed, and, therefore, its counter E. M. F. will necessarily be very low when the train is started, and much below the maximum when the train is under part headway. It is true that the counter E. M. F. may be kept up when running slower by increasing the strength of the magnetic field, which will have the same effect as keeping up the speed, but then the field will require more current to feed it, and this current is an absolute loss.

The difficulty of the railway problem, therefore, consists in devising some form of *smooth-running, high speed, reliable mechanical* connection to the driving wheels, which will enable the motor to be run at a practically constant and high speed, whether the train be moving slow or fast. Two different rates of gearing at least will probably be required—one to obtain the requisite pull to start with, and the other when the train is moving at more than half speed. With such an arrangement a mean counter E. M. F. of perhaps 50 or 60 per cent. can be obtained on the elevated railroad, and this would give a net efficiency between the belts of the stationary engines and the driving wheels of the electric locomotives of from 40 to 50 per cent. Taking the lowest figure, and applying it as a coefficient of transmission to the original power, shows that 7.5 pounds of coal an hour in the stationary engine will furnish 1 h. p. on the track. As the present steam locomotives require over 19 pounds, this effects a saving of over 60 per cent of the coal.

Suppose that upon the second avenue line, for example, there are throughout the 24 hours on an average of 20 moving trains, each requiring 500 lbs. of coal an hour, or 240,000 lbs. for all for 24 hours, at $4 per gross ton, which amounts to about $436 per day. Sixty per cent. of this, or $260 per day, which is equal to 5 per cent. per annum on $1,898,000, would be saved in coal alone by the change.

It has been said that suitable electric locomotives would cost considerably less than the steam locomotives (which cost about $6,500 apiece), on account of their simplicity and absence of accurately fitted and steam working parts. Electric locomotives, however, have not been a regular machine-made gradually-developed article of manufacture for 20 years and more, like steam locomotives, so that, in spite of their simplicity, which will certainly prevent them from wearing out anything like so rapidly, it will be safer to assume that the cost of the first ones, including all necessary experimentation, will greatly exceed what would be supposed.

Whether the present firemen could safely be dispensed with in the electric locomotive, as has been suggested, is very questionable. Probably the passengers would prefer not to trust their lives to a single man in the engine any more or as much as to a single pilot at the wheel of an East River ferry-boat.

To transform the steam equipment of the elevated roads into an electrical equipment is now beyond a doubt a possible thing; but to make it equally efficient and reliable, and to do it without interrupting the very important travel, or causing accident, will require the very best electro-mechanical engineering ability, or else a long period of slow development. It seems now as if the problem were likely to receive more of the latter.

THE EDISON SYSTEM OF UNDERGROUND CONDUCTORS.[1]

THE essential form of the conductors exhibited by this company is that of an iron tube containing one or more copper conductors insulated from each other and the enclosing iron tube, and having all remaining spaces in the latter filled with an extremely viscous, almost solid, insulating compound, which becomes fluid at a high temperature. This manufactured product is termed an "electric tube." These tubes are manufactured in fixed lengths, generally 20 feet. The conductors project from two inches to three inches beyond the end of the enclosing iron tube, and two lengths of electric tube are joined together by means of copper joints soldered to the projecting conductors, and so formed as to allow the expansion of the conductors to take place without injury or danger. Such joints are protected by a cast iron box completely enclosing them and securely fastened to the ends of the tubes enclosing the conductors. This box is then filled with the same compound as the tube and hermetically sealed.

The exhibit of this company showed the great range in the size and number of conductors which the fundamental form of cased conductor permits, and the great flexibility in making circuits of complicated ramifications, which is given by the plan of having joints at frequent intervals; and the methods of making these joints.

To illustrate the range in size, etc., samples of electric tubes were shown containing conductors varying in number and size, from a single round conductor 1·61 inch diameter, of 2,592,100 circular mills or 2·036 square inches sectional area, in an iron tube 2¼ inches outside diameter, to 271 wires No. 14 Brown & Sharpe gauge, of 4,100 circular mills or ·00322 square inch sectional area, in an iron pipe 3¼ inches outside diameter.

To show the manner in which circuits of a complicated character may be made with this form of conductor, circuits such as those used for incandescent lighting on a large scale, having a large number of derived circuits with conductors of widely differing sizes, there was exhibited a portion of an underground circuit such as is used in T. A. Edison's 3-conductor system of incandescent lighting—a system using tubes, of which the cross-section is shown by figure 1.

This exhibit consisted of, first: a "junction safety catch box." This is a large round box the top of which is flush with the surface of the street; it is provided with a loose outside cover, and a lighter inside cover bolted down to make a water-tight joint with the box; these being removed, disclose the internal electrical connections in a readily accessible position, six inches below the surface of the street. The central portion of the box is occupied by the "pole pieces," consisting of as many rings as there are conductors in the system (in this instance three), each ring having as many radial projections as there are tubes entering the box (in this instance six), these projections, which are symmetrically arranged as regards polarity, are all brought to the same level at their extremities and terminate in plane, polished, gold-plated surfaces one inch square, which are arranged equidistant from each other in a circle around the centre of the box. Each of these surfaces has a tapped hole in the centre.

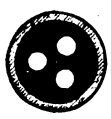

FIGURE 1.

In a circle outside the pole pieces are as many "safety catch joints" as there are conductors entering the box (in

1. Statement furnished by the Edison Electric Tube Company, and edited by the Board of Examiners of the Electrical Exhibition of the Franklin Institute. From the *Journal of the Franklin Institute* [*Supplement*].

Digitized by Google

this instance 18); these safety catch joints are arranged radially opposite the extremities of the projection of the pole pieces; each consists of a copper or composition piece, which has a copper rod soldered into it, projecting about eight inches downwards into the body of the box, the upper end of the composition or copper piece terminating in a plane, inch-square, gold-plated surface, the same as those on the pole pieces. These surfaces of the safety catch joints are on the same level as the similar surfaces on the pole pieces, and radially opposite and equidistant from them.

Two feet below the top of the box (that is, the surface of the ground), the electric tubes (in this instance seven) enter the box and are rigidly attached to it, the joint being made water-tight. The pole pieces and the safety catch joints are all insulated from each other, but rigidly attached to a support rising in the centre from the bottom of the box.

Flexible copper cables join each conductor, of each tube, with one of the copper rods which project downwards from the safety catch joints, so that by means of flat safety catches placed across from the safety catch joints to the corresponding projections of the pole pieces, all conductors of like polarity are joined together at this point with a safety catch in each circuit in a readily accessible position, where it can easily be removed or replaced. Such a box equalizes the electromotive force at that point of all lines entering it, or if one of the tubes is a feeder, that is, runs back to the dynamos, the box is a distributing point for several circuits which may or may not be brought together again at some other place.

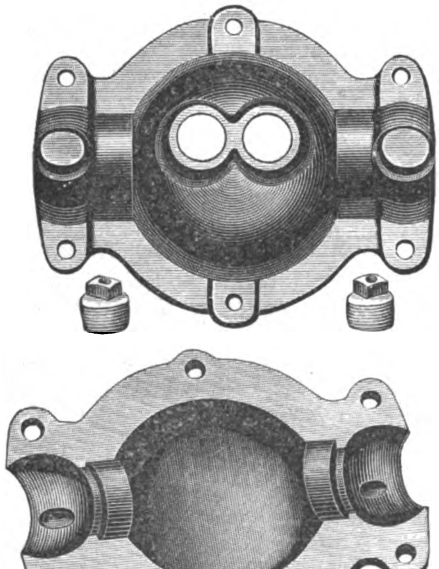

FIGURE 2.

The conductors in the tubes entering this box may be of any size to suit the requirements of the different circuits. The circuits shown entering this box vary from 350,000 circular mills to 133,000 circular mills area of conductor, and are arranged to show how they may be laid, bent in different degrees to right or left, joining each other at their extremities; crossing each other and joined together at the crossing; joining other circuits at any point in the length of the latter; reduced in size at any point of their own lengths, and having derived circuits of any size taken from them at any point of their own lengths; and having all these varied connections of different sized conductors made by means of a comparatively small number of standard patterns of connecting joints, boxes covering the joints, and ball clamps attaching the boxes to the iron tube enclosing the conductors.

The ball clamps, in connection with the boxes, are essential features of all underground conductors of this company's exhibit.

Figures 2, 3 and 4 illustrate the forms of these parts and the manner in which they are used.

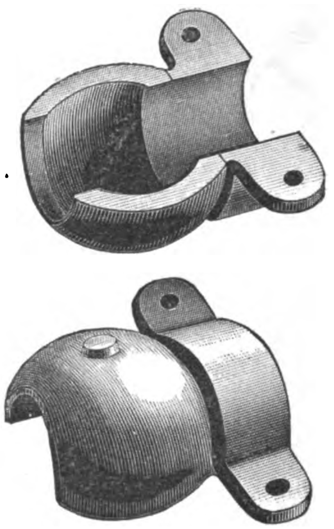

FIGURE 3.

Figure 2 shows the top and bottom halves of a "coupling box," a 3-conductor system, and figure 3 a "ball clamp," whilst figure 4 shows the bottom half of the same coupling box with tubes and ball clamps in place and joints connected. The two parts of the ball clamp being bolted together on the tube are thus securely clamped to it; the hemispherical parts come together to make a sphere, which fits the spherical socket in the nozzle of the box; the two together thus form a ball and socket joint, allowing free angular movement of the tube in any direction, but preventing longitudinal movement of the box on the tube. The angular movement allowed by the ball and socket is limited to any amount in any direction, by providing a rib inside the box (either separate as in figure 11, or forming the inside opening of the ball-socket of the box, as in figure 2) of such a form, that when the extreme amount of angular movement to be allowed in any one direction is obtained, the tube projecting into the box through the ball clamp comes in contact with this rib, thus stopping any further movement in this direction.

The box is made of such size and form that when the tubes have the extreme angular movement allowed there is still ample space between the joint and the box to prevent the two coming in contact. Rotary movement of the box on the tube is prevented by means of the small lug on the

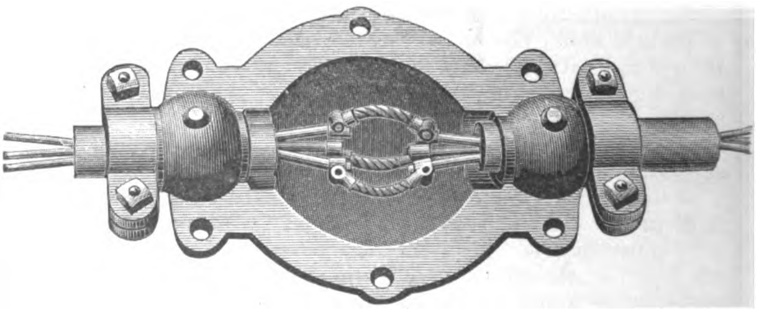

FIGURE 4.

ball of the clamp which loosely fits sidewise, the slot shown in the socket of the box, the slot being sufficiently elongated

Digitized by Google

lengthwise that the lug may have free play in that direction within the limit of angular deviation allowed.

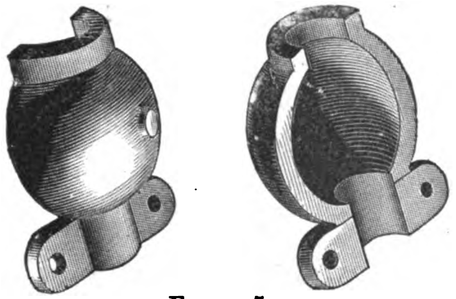

FIGURE 5.

The limiting rib inside the box is made to give the angular movement allowed, when the largest size of iron tube that will go into the box is used, but any smaller iron tube may be used in this box (as, for example, in reducing the size of the conductor at this point) by means of a ball clamp, of the form shown in figure 5, with a ball to fit the box, but with a smaller semi-cylindrical groove in each half to fit the smaller iron tube; this clamp has in addition, as shown, a semi-cylindrical ring concentric with the groove cast on the ball of each half; the two, when the two halves are clamped together on the iron pipe, forming a cylinder projecting into the box, of the same outside diameter as the largest iron tube that will go in the box; this projection on the clamp striking against the limiting rib inside the box, limits the angular movement of the smaller iron tube to the same amount as when the largest size of iron tube that will go in the box is used. Therefore the ball clamp and box, as described, whilst making the iron envelope of the conductors mechanically continuous, and preventing rotary movement of the boxes on the tube; allow an angular deviation (in this case 1 to 10) in every direction, at each end of every box, which gives a degree of flexibility to the whole line (in this instance 11½ degrees at each joint) and at the same time renders it impossible that the joint should touch the box, with the extreme amount of angular deviation allowed. The ball clamp, modified as shown in figure 5, also permits the use in any box of any tube smaller than the largest that will go in the box, whilst preserving the same limit of angular movement.

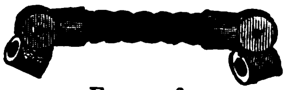

FIGURE 6.

The flexibility of the whole line thus obtained is necessary for rapid and cheap laying in streets, where, from the number of gas, water and other pipes, sewer-manholes, etc., it is impossible to run tubes in a straight line for any distance.

The joints for 3-conductor tubes consist of pieces of copper wire rope having cast or brazed on their ends suitably shaped composition sockets, in which are drilled holes to fit the size of copper conductor for which they are intended, and to which they are soldered in laying the line. The

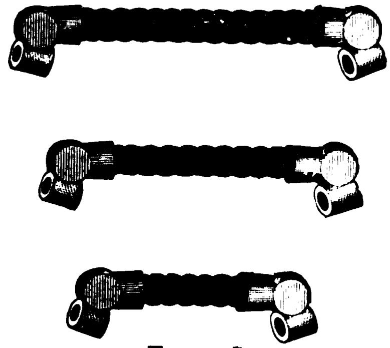

FIGURE 7.

joints necessary to obtain the results illustrated by the exhibit are: "Coupling joints," for connecting two tubes in a straight line (figure 6 shows the form of one piece, three such pieces being used for a complete joint); "90° elbow joints," for bending 90° to right or left, and "45° elbow joints," for bending 45° to right or left. Figure 7 shows three forms of pieces, different combinations of which will make all kinds of elbow joints. "Branch joints," by which, to any coupling joint in a line of any sized electric tube, may be attached a branch to one side, or one to each side, of any sizes not larger than the main line. Branches of sizes larger than the main line, being of rare occurrence, are not allowed for in the standard patterns for branches enumerated below, but, when required, may be made by a slight modification of the latter. Figure 8 shows three forms of pieces, different combinations of which will make,

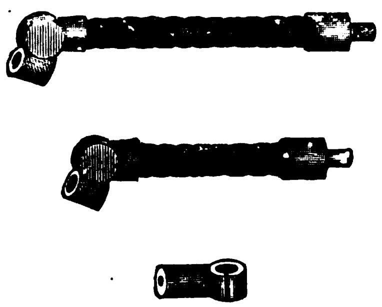

FIGURE 8.

to either or both sides of any coupling joint, branches of all sizes ordinarily required; a few of the largest sized branches require special patterns of modified forms, which are enumerated below. The form of socket of the coupling joint shown in figure 6 gives the copper wire rope of

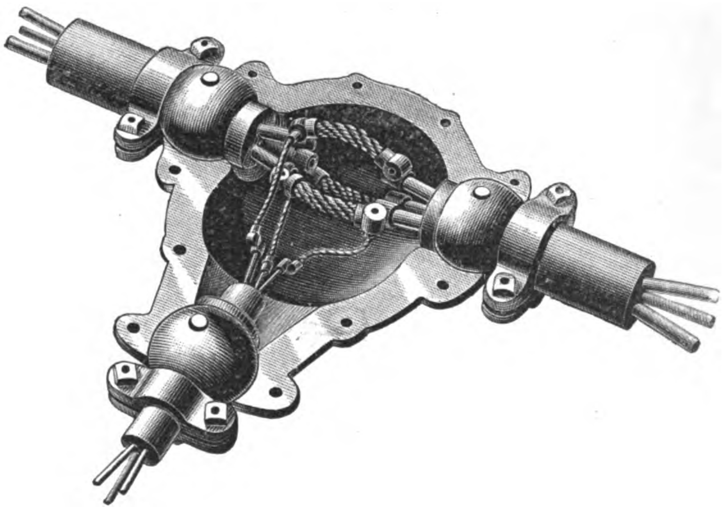

FIGURE 9.

the joint a bowed form when the joint is in place, to allow for the expansion of the conductors in each electric tube. The form of the joint when in place is seen in figure 4. Figure 6 shows that, in addition to the hole which fits the conductor, each coupling joint socket has another hole drilled in it; the male sockets on the ends of the branch joint pieces (see figure 8) fit these holes and are soldered in them in attaching a branch joint; the female sockets on the other ends of the branch joint pieces are drilled to fit the conductors of the electric tube used for the branch lines. Figure 9 shows a coupling joint, with a branch joint attached, in the bottom half of the box used for covering this kind of joint.

The 3-conductor system, so far as it is exhibited, has 21 different sizes of electric tubes, having conductors varying

Digitized by Google

from 500,000 to 72,000 circular mills sectional area. The enclosing iron tubes are of five different sizes, varying from 2$\frac{3}{8}$ inches to 1$\frac{1}{16}$ inches outside diameter. All connections are made with 10 patterns of boxes, eight patterns of ball clamps, and patterns of 43 pieces for all joints ; of the latter, six patterns are required for coupling joints for all sizes, three of these patterns are also used for elbow joints, which require 15 patterns in addition, making 21 patterns for all varieties of all sizes of coupling and elbow joints. The remaining 22 patterns are for branch joints, and 12 of these will make any combination ordinarily required, the other 10 being for use in cases which rarely occur.

Electric tubes are exhibited cut away to show the internal construction, which consists in wrapping each copper conductor with a layer of insulating tape, and winding each taped conductor spirally with rope impregnated with insulation ; the pitch of this winding is large compared with the diameters of the rope used, so that the windings of the several conductors fit between each other when the conductors are placed together ; as many conductors as are to go in one tube, being so placed together, they are bound together by a final spiral winding of rope around them all, and the bundle of conductors thus formed being introduced into an iron tube, the process of manufacture is completed by filling the tube with insulating compound liquid, at high temperature, ready access being afforded the latter throughout the length of the tube, along the spiral paths formed by the rope-winding of the conductors.

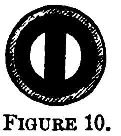

FIGURE 10.

Another variety of electric tube is illustrated by an exhibit of a complete set of sample tubes for the two-conductor system of incandescent lighting, and typical examples of the boxes, ball clamps and joints used with them. The conductors in this system vary from 1,639,890 circular mills, or 1·2879 square inches, sectional area in a tube 3½ inches outside diameter, to 33,015 circular mills, or 0·02593 square inches sectional area in a tube 1$\frac{1}{16}$ inches outside diameter, and, there being only two in a tube, economy of space in the latter is secured by making the conductors in the form of segments of circles, as seen in figure 10, which shows a cross section of one of these tubes. The joints for these tubes are of cast copper, the allowance at coupling joints for expansion of the conductors being given by making the joints with a U-shaped bend, projecting at right angles to the line of the tube, the section of the joint in the U being flattened to a paralellogram, long in comparison with its width, as is seen in figure 11, which shows a coupling joint for this system of tubes, with bottom half of coupling box. Holes are bored in all joints of the same form as the conductors for which they are intended, and to which they are soldered in laying. Boxes are exhibited with short tubes entering them, and joints connecting the latter, showing the forms assumed by different sizes and varieties of coupling elbow and branch, joints and boxes. Figure

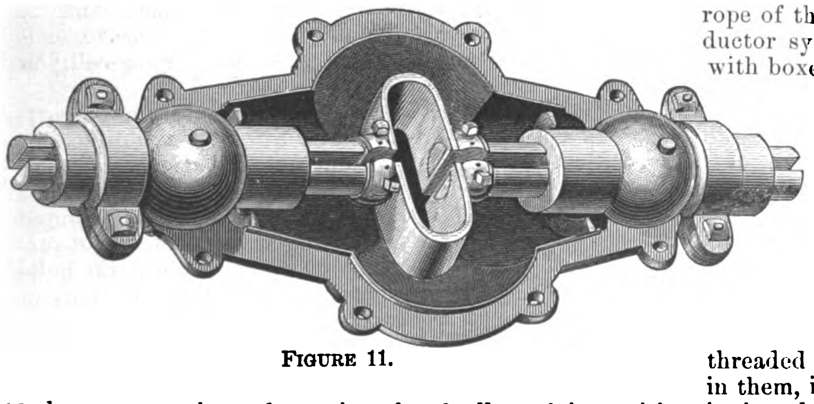

FIGURE 11.

12 shows one variety of one size of 90° elbow joint, with bottom half of elbow box.

In both the three and two conductor systems, boxes and joints are shown for use in in-door lines of these tubes. The flexibility of the line which is required for underground work, and which is given by the ball and socket connection of clamps and boxes is not necessary in in-door lines ; the boxes may therefore be smaller on this account, and also on account of the absence of the ball clamps, the

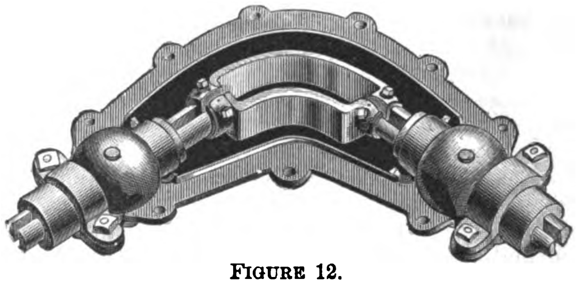

FIGURE 12.

mechanical continuity of the iron envelope of the conductors being secured in small space by means of a ring which is screwed on the threaded end of the iron pipe and fits in a groove cast in the neck of the box (which neck fits the iron tube) ; this box is made in halves, which are bolted together over the joint, the end of the tube, and the ring screwed on the latter.

Underground arc light circuits were illustrated by two exhibits showing the character of the tubes and joints and the method of taking loops to lamps. One showed tubes with two round conductors for a complete circuit in one tube.

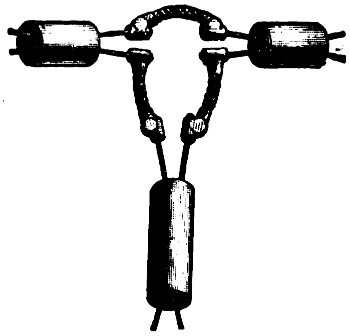

FIGURE 13.

Figure 13 shows this exhibit, and the method of making the joint so that, the branch tube being led off to a lamp or lamps, the two conductors of the branch form a loop of the main line. The second exhibit shows the case of a circuit completed by a line on another street. In this exhibit the main line tubes entering the box have only one conductor each, the conductor of each tube being joined to one of two conductors of the third tube, forming a loop from the main line of a single conductor. The joints are of wire rope of the same character as the joints for the three-conductor system. Ball clamps are used to connect tubes with boxes.

A distinct variety of electric tube is that designed for telegraphic and telephonic use. In this case, the conductors being large in number and small in size, instead of the spiral rope winding round each conductor, the insulating covering is continuous, and a rope winding is only used round the outside of a bundle of such wires. The wires are laid together regularly, on the basis of a hexagonal cross section for the bundle, and at each end are threaded through wooden screens which have holes drilled in them, in the same relative positions as the wires occupy in the tube. At one end of each tube, before being threaded through the screens, the wires are woven together so as to change the relative positions of the wires. This operation

Digitized by Google

of weaving is simple and systematic, and the same for all tubes with the same number of wires, and is arranged on such a basis, that in conjunction with a systematic rotation of consecutive tubes, alternately to right and left, in the process of laying, it produces, in a series of long period, methodical changes in the relative positions of the wires in consecutive tubes, for the purpose of neutralizing the effects of induction. In making the joints of these tubes, wires threaded through corresponding holes in the screens are bent outwards and placed together in the same notch of a series of notched wooden slats, one for each layer of wires in the joint, which are built up one above the other, as the process of making the joint proceeds. When all the wires are so bent out, the ends are clipped off, leaving about one inch projecting through the wall of notched slats; the insulation is then slipped off the ends and each pair joined by a small sleeve, which is soldered to them to make the joint. In general, the joints of half the wires are made on one side and half on the other side of the box. Grooves are provided in the boxes into which they fit the wooden screens through which the wires are threaded, and the series of wooden slats built up in making the joint, holding these securely in place. By this method of making the joints, every joint of every wire, at intervals of 20 feet, is brought into a position in which it is readily accessible for purposes of testing, making connections, etc., without interfering with any other wire, so that at any such joint, loops or single service wires may be attached to any or all of the wires in the line. A line of this character, containing 37 wires was exhibited, with several consecutive boxes and joints to show the system of weaving wires in conjunction with alternate rotation of tubes. Such a line is adapted more particularly to telegraphic uses. Another box was exhibited, constructed with especial reference to the needs of telephone service, for which, in addition to trunk lines between stations, a number of wires are required for services in each block, and only run from the station to that block, thus giving a line between two stations a size decreasing gradually from each station to some point between them. The box exhibited, which showed a joint in a line of 217 wires, had a low turret rising from its upper half, the top of this turret was closed by a loose outside cover and an inside cover bolted down, and making a tight joint with the box by means of a rubber gasket; the whole being made water-tight by filling the space between the two covers, with the insulating compound. In every such box, along the face of a block, all those wires which are intended for use as services in that block, are bent upwards instead of outwards, in making the joint so that the joints of all such wires project upwards into the turret and are held in position by a wooden frame shown, whilst the joints of all other wires are made out to the sides at a lower level; this arrangement allows the box to be filled with insulating compound, covering all the wires and all joints, except the joints of those wires intended for use in that block, which latter joints project up above the surface of the compound, and on removing the cover of the turret are all immediately accessible at every box along the block, for attachment of services, to any or all of them. Tapped holes are provided around the turret on the level of the joints of service wires, into which service tubes may be screwed, if electric tubes are used, or brass nipples to which are soldered the lead covering, if lead covered wires are used for service connections.

This company also exhibits specimens of lead covered wires of small sizes, and a specimen of flexible heavy conductor for indoor use with large currents, consisting of copper wire rope, taped, wound and lead covered. They also exhibit specimens of insulating tape, in rolls of 125 feet, continuous length, varying in width from six inches to ¼ inch, and jars of the insulating compound used in the tubes and boxes.

COMMENTS BY THE EXAMINERS.

This system may be summed up as belonging to division "A a" of the Section's arrangement, or that in which the electrodes are permanently sealed. When any portion of an electrode is destroyed a new one is not introduced, but a new length of pipe is substituted, containing the necessary number of wires and attached at its extremities. The details are very fully given, and with the cuts render it unnecessary to repeat them. With a large stock of lengths and boxes and with trained workmen, the work of laying the conductors only a few inches below the surface of the streets would be comparatively rapid. While in the tentative stage of underground service this does not present the same amount of convenience as a system where wires may be introduced and removed at will; and presents the objection common to all "section" systems that the conducting capacity of the whole line is that of the most imperfect of splices made every 20 feet, yet it answers the demands upon it much better than those systems which require expensive and tedious derangements of the street in order to accomplish repairs. The seat of an accident to one of the wires of this system is located from the central office, on and between known streets. The manhole is opened and the safety catches first of all examined. The managers assert that the place of the break can then be so accurately located that the length containing it (usually about 20 feet) may be at once removed and replaced by another.

The telephone and telegraph, and the light and power wires are not enclosed in the same tube. The insulating material with which the boxes are filled is still flexible at 32° F., but brittle at 0° F.

The method of laying and tapping for private dwellings would seem to afford complete protection against lightning. The three-wire system which has been grafted upon the Edison conduit system effects a saving of 62 per cent. on that required for the two conductor system, in the copper necessary for conductors.

The light and power system are not adapted for use by various companies, independently, though the telephone and telegraph conduits might be so applied.

The details of this system have been so perfectly elaborated, that in view of the fact that no complete description of it has been heretofore made public, the examiners deemed the above full report desirable.

ABSTRACTS AND EXTRACTS.

A NEW STORAGE BATTERY.[1]

BY EMILE REYNIER.

THE new electrical accumulator manufactory of Messrs. Blanc & Co., at Marly (Switzerland), is making its existence felt by putting on the market several perfected models, adapted to the diverse exigencies of the industrial applications of the storage battery. Among the most recent types, is a small zinc storage battery intended to replace the primary cells hitherto used for telegraphy, telephony, railway signals, call bells, etc.

The couple (see cut) bears an exterior resemblance to the ordinary Leclanché cell; and this resemblance extends to the cylindrical amalgamated zinc and porous cell, but ends there.

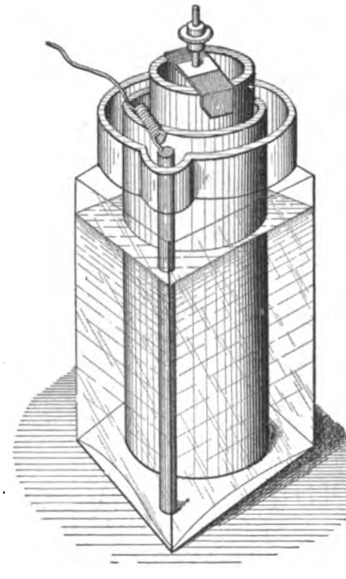
The positive electrode, placed in the interior compartment, is a sheet of peroxydized lead, folded in 3 directions longitudinally, pierced by numerous transverse slits, and rolled into a spiral; it is reinforced at its upper part by a diametrically placed cap or clamp of copper, surmounted by a screw-post for the connecting wire. The useful surface of the electrode is about 62 square inches; the holes with which it is pierced putting the interior portions in communication with the exterior.

The liquid is a solution of bisulphate of potash. This salt in crystals is placed in the central space left by the lead electrode.

1. *L'Electricien.*

Digitized by Google

To put the battery in operation, it is only necessary to pour water into the 2 compartments. The acid salt dis-



solves gradually in the porous cell; it diffuses slowly and without great excess in the exterior compartment, where it dissolves the zinc when the circuit is closed. This couple operates like my ordinary zinc storage batteries, with this difference, that in this case the sulphuric acid is borrowed from the bisulphate of potash. The salt yields an equivalent of acid, the chemical reactions involve then, 2 equivalents of bisulphate.

The substitution of the bisulphate of potash for the free sulphuric acid, and the use of a porous cup, have for their objects the almost entire suppression of local action on the zinc.

	Small zinc accumulator.	Leclanché cell with 2 plates.
E — electro-motive force { initial, in volts	2.37	1.48
E — electro-motive force { in use, "	2.2	1.2
R — resistance, in ohms	0.4	1.1
Q — electro-chemical capacity, in coulombs	54,000	52,000
I — normal strength of working current, in ampères	1.	0.08
i — strength of charging current, in ampères	0.3	
EI — performance of work, in watts	2.2	0.12
QE — total work, in k g m	11,000	6,200
g. Length and breadth, in inches	3¼	3¼
Total height, in inches	7¼	7¼
Total weight, in lbs.	5	4¼

One may estimate from the above figures the value of the small zinc accumulator relatively to that of a Leclanché cell of the same size.

The table shows evidence of the superiority of the small zinc accumulator over the Leclanché cell; its electromotive force, its delivery, and its total work are greater, while its resistance is much smaller—a useful quality in all of its applications, but especially valuable when used on the carbon transmitters of telephone systems, for it renders the variations in the resistance of the transmitter more sensible, and in consequence augments the strength and clearness of the sounds transmitted.

In practice, one of these accumulators will fully replace two Leclanché cells of the same size. The retail price of both being about the same per cell, the substitution of the new system for the old will result in a saving of 50 per cent. on the cost of installation.

We shall see that the economy in maintenance is greater still.

The regeneration of the accumulators may be effected in two ways:

First.—By replacing the electrodes and exhausted liquid; it is necessary then to replace only 1 zinc instead of 2, a lead plate instead of the 4 agglomerated plates, and 150 grammes of bisulphate of potash instead of 200 grammes of sal ammoniac.

Second.—By passing through the cell, during 40 to 50 hours, a current of above .5 ampères, furnished by a dynamo machine. The expense of this work is, at the most, about 1-10th of 1 h. p. This method, being much more economical than the first, would be exclusively employed where the accumulator was used on a large scale for telegraphy and telephony.

The small zinc accumulator possesses a great elasticity of performance; it may either expend its charge in a few hours, or extend its work over a period of six months.

Under ordinary circumstances, the regeneration should be practiced at intervals of 3 months. As the electrodes will bear 100 chargings, the life of the accumulator will exceed 25 years.

For some time past it has been desired to replace the costly work of primary batteries by that of machines; but outside of central stations employing thousands of cells, the substitution is neither convenient nor economical. The use of accumulators, which allow of the division, the distribution, and the storage of the work of the machines, will remove all of these difficulties. Accumulators may be introduced without embarrassment to the staff, since they bring no other modification of the service than the employment of a lesser number of cells by one-half—and without any sacrifice to the owners, since the jars, zincs, and porous cells of the Leclanché system, both old and new styles, would be utilized. The latter consideration induced me to arrange the small zinc accumulator in the same size and shape as the Leclanché cell, which it is intended to replace.

A SCALE OF HARDNESS FOR METALS.

THE following is a scale of hardness in use in the laboratory of the Technical High School at Prague, composed of eighteen metallic substances, arranged in ascending order from the softest to the hardest:

1. Pure soft lead.
2. Pure tin.
3. Pure hard lead.
4. Pure annealed copper.
5. Cast fine copper.
6. Soft bearing metal (copper, 85; tin, 10; zinc, 5).
7. Cast iron (annealed).
8. Fibrous wrought iron.
9. Fine-grained light-gray cast iron.
10. Strengthened cast iron (melted with 10 per cent. of wrought turnings).
11. Soft ingot iron with 0.15 per cent. carbon (will not harden).
12. Steel, with 0.45 per cent. carbon (not hardened).
13. Steel, with 0.96 per cent. carbon (not hardened).
14. Crucible cast steel, hardened and tempered, blue.
15. Crucible steel, hardened and tempered, violet to orange-yellow.
16. Crucible steel, hardened and tempered, straw-yellow.
17. Hard bearing metal (copper, 83; zinc, 17).
18. Crucible steel, glass hard.

TEST FOR LUBRICATING OIL.

PLACE a single drop of the different kinds to be compared in line across the end of a piece of plate glass about 24 in. long, one end being placed 6 or 8 in. higher than the other, to form an inclined plane. The drops of oil run down this smooth plane in a race with each other. The quality of the oil for lubricating purposes is shown by the distance traveled, and the trace left by the drops. Thus, on the first day, sperm oil will be found in the rear, but it will in time overtake the rest, and retain its power of motion after other oils have dried up. A light bodied oil flows quickly, like water, but also dries, whereas what is needed is a good body compared with a limpid flow. Many oils have a good body, but have a tendency to gum, and will be distinctly shown upon the glass.—*Chemical Review.*

ELECTRICAL ILLUMINATION IN MICROSCOPY.[1]

BY E. A. SCHULTZE.

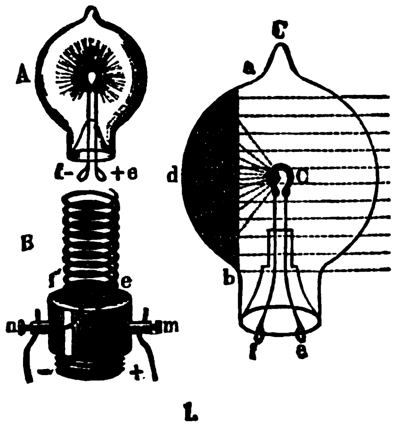
THIS subject has for some time had the attention of scientific men both in this country and in Europe. Among the first to note the advantages of the electric light in microscopical research, figures Dr. Henri Van Heurck, of Antwerp, a student who ranks as high in Belgium as does Mr. Edison in the United States. His investigation began, about ten years ago, with a trial of the effects of a galvanic battery on platinum, but the trial yielded no satisfactory results. He was the first to employ the Swan lamp for microscopical illumination, the experiment being made at the Paris Exposition. Shortly afterward, in November, 1881, with a view to greater progress in this work, Mr. Swan endeavored to manufacture the smallest possible lamps; and in the following January he constructed one which required only seven volts, or the power of four Bunsen elements, and sent it to Dr. Van Heurck. The latter carefully tested its usefulness, and he published the results in the Proceedings of the Belgian Society of Microscopists. In March, 1882, a committee of that Society visited him for the purpose of witnessing his methods and measuring their success. Before the end of that year he published in the Bulletin of the Society an extended article on the adaptability of electrical illumination to the microscope, in which he gives a theoretical explanation of the superiority of the electric light over all others, and much useful information, besides, regarding its practical working. He found that for the resolution of diatoms, as well as for all other work requiring objectives of high power, the light furnished by his electric lamp, when fed by a suitable battery, was better by far than any he had previously employed; also that an electro-motive force of six or seven volts amply suffices for all uses.

The views of Dr. Van Heurck are ably seconded by Dr. Theodor Stein, of Frankfort-on-the-Main, in an article contributed by him to the "Zeitschrift für Wissenschaftliche Mikroskopie," Vol. I., No. 2 (1884). I have made a digest of such parts as are material to my purpose, as follows:

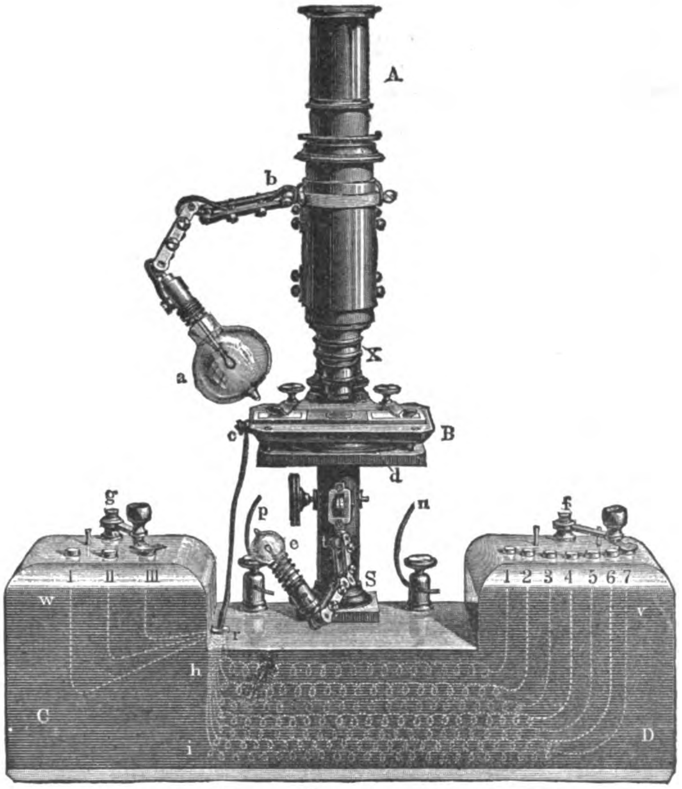
"The electric light," says Dr. Stein, "has been in use many years for showing microscopic objects by projection upon a screen with the use of the magic lantern. With constant improvement in the manufacture of objectives, the discernment of fine structure was possible even by this method. But the excellence of the performance found its limit at a power of 80 diameters, a higher amplification seriously impairing definition.

"At the Electrical Exhibition in Munich, in 1882, trial was made of the advantage of electrical illumination in working with the compound microscope. The light furnished was found to be sufficient for the finest observation with objectives of the highest power, and to be free from the well-known disadvantages of other kinds of artificial light—the yellow ray and the heat ray. All possible preparations were examined, such as muscle, nerve, epithelia, bone, skin, bacteria, diatoms, etc. Especially surprising was the faultless picture of the red blood-corpuscles, to the correct showing of which a yellow light is particularly inimical. In the region of blue and violet, the spectrum of the light from an incandescence lamp is incomparably more intense than that of light from any other artificial source. In these observations light of different intensities was used, ranging between 16 and 60 candle-power, and was received by the substage mirror and was reflected thence upon the object.

"These experiments suggested to me, in the winter of 1882, the idea of setting aside the mirror, and placing the incandescence lamp beneath the stage for the direct illumination of the object. As no lamp small enough for the purpose was in existence, I requested Mr. C. H. F. Müller, of Hamburg, to make me some according to certain specifications which I gave him. At this time appeared in the Journal of the Royal Microscopical Society an article by C. H. Stearn, who, at a meeting of the Society, held January 10th, had exhibited a microscope furnished with electrical illumination. I again conferred with Mr. Müller; and I now have lamps, manufactured by him, which suit my purpose. Illustrated at A, figure 1, is a small lamp; at C, a larger one. Each consists of a glass globe, at the exact centre of which is a horse-shoe carbon supported by two platinum wires. The wires terminate outside the globe, in the eyes *f* and *e*. The neck of the lamp A is forced into the spiral spring B, and connection is made with the hooks f^1 and e^1. The spring presses the lamp upward, and thus brings about an intimate contact of the eyes *f* and *e* with the hooks f^1 and e^1. These hooks communicate with two conducting wires *m* and *n*, which are let into a hard-rubber screw. The screw itself is attached to the extremity of a jointed arm articulating with the microscope as shown in figure 2. To bring a lamp of the smaller size to a brilliant white heat, a current from two Bunsen or Grove elements 20 cm. high, is sufficient. The lamp C, figure 1,



1.



2.

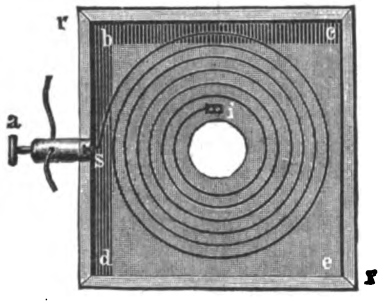
1. *Journal of the New-York Microscopical Society.* Read Nov. 7th, 1884.

Digitized by Google

having a larger carbon, will require three elements. Should a stronger light in any direction be required, a part of the globe, as seen at *d*, figure 1, may be silvered on the outside so as to act as a reflector. For lamps to be used with low-power objectives, opal glass is preferable to common glass, as the light through it is less fatiguing to the eye.

"In figure 2 we see a small lamp, *e*, and a larger lamp, *a*, attached to an upright microscope. The foot, S, of the instrument is screwed to a wooden box, C D. For facile movement in every direction, both lamps are supported by arms furnished with ball-and-socket joints.

"The wires from the battery are fastened to the instrument by the binding-screws *p* and *n*. From the screw at *n* a concealed wire goes direct to the foot, S, of the stand, and beyond this point the microscope itself serves as a conductor communicating with the lamps *a* and *e*. The return wires are well insulated. That from the lamp *a* runs along the jointed arm *b*, then down the back of the stand and along the side of the stage to the support *c*, and thence into the box through the aperture *r*. That from the substage lamp runs along the jointed arm *t*, then behind the stand and by the side of the stage to *c*, and thence it accompanies the first wire. Besides these there is a third wire, also insulated, and passing downward, which is attached to the stage. Between *c* and *r* the three are bound together in one bundle. The communication between the binding-screw at *p* and the lower end of one or other of the three wires entering the box at the orifice *r*, takes place through an important subsidiary apparatus, the rheostat, and is regulated by means of the switches *g* and *f*. The switch *f* and the spiral german-silver wires, *v i h*, constitute the rheostat, by means of which the electric current can be strengthened or weakened at pleasure. The wires have different diameters, and thus oppose to the current differ-



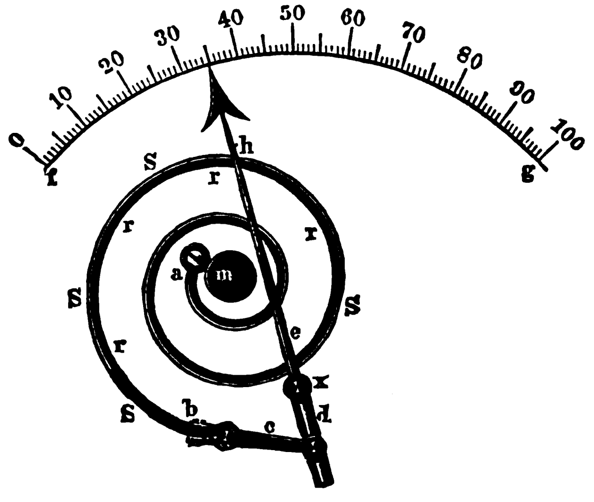
3.

ent degrees of resistance. If a small battery of two elements be used, the rheostat is superfluous. But if a powerful battery be employed, the current will, unless subdued, be too strong for the lamps, and will destroy them.

"The operator begins work by sliding the switch *g* to the proper point. He will move it to the knob I if he wish to use the upper lamp, to the knob II if the lower, and to the knob III if he desire the current to traverse the stage, B, alone. Next, to adjust the current to the size of the lamp, the power of the objective, and the character of the object under investigation, he will first place the switch *f* on knob 1, and then will cautiously slide it to knobs 2, 3, 4, etc., until the required degree of illumination is obtained."

Dr. Stein next gives the construction of what he would call an "electrically-heated stage." Between the two plates of the stage is placed a platinum spiral, figure 3, which may be heated by the electric current so as to raise the temperature of an object under examination. The degree of the heat is easily controlled by the rheostat, and it may be measured by means of a spiral bimetallic thermometer. In the illustration, figure 4, *r* and S are ribbons of iron and brass, soldered together. The inner end, *a*, is screwed to the stage close to its opening, *m*. The free end, *b*, acts upon an index, *d*, which is pivoted at *x*, and whose point traverses the graduated arc *f g*.

The rest of the article treats, in a full and interesting manner, of the application of electrical illumination to photomicrography, and describes a form of stand especially



4.

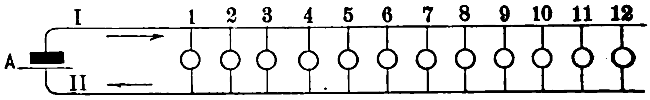
adapted to that department of microscopical work. The details cannot be given here. One or two facts, however, I must note,—the microscope has a vertical position instead of the usual horizontal one, and the illumination necessary for taking a most excellent photograph of *Pleurosigma augulatum* costs an electromotive power of only five volts.

Dr. Stein concludes his article with an expression of confident belief that the microscopist who has once employed the electric light for his researches, will thenceforward use no other.

EDISON'S THREE-WIRE SYSTEM OF ELECTRICAL DISTRIBUTION.[1]

BY H. M. PAUL.

THE three-wire or multiplex system of distributing currents for electric lighting over large areas, as devised and used by Edison[2], is highly ingenious, and effective in reducing the necessary size of the large copper conductors. The size of the conductor must be proportioned to the maximum number of lamps which it will ordinarily supply. This number being given, the size should be such that the resistance of the metallic part shall bear a fixed ratio to that of the lamp part of the circuit; and the value of this ratio will be determined by the condition that the additional running expense due to the resistance of the conductor shall equal the interest on its first cost, so far as this depends upon its cross-section.



TWO-WIRE SYSTEM.

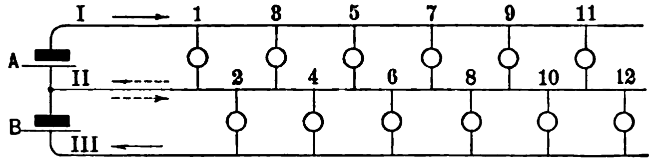
In the two-wire system, A is the dynamo, which we will suppose to keep up a difference of potential of 100 volts between the conductors I and II. Across these are bridged 12 lamps of equal resistance, representing what would be, in practice, several hundred dwellings, factories, churches, theatres, etc.

The next figure shows Edison's three-wire modification of this. A and B are two dynamos coupled in series, with conductors I, II, and III leading out as shown. As A and B each keep up 100 volts, as before, the difference of potential between I and III will be 200 volts. The 12 lamps are

1. *Science*.
2. See U. S, Patent of T. A. Edison, No. 274,290, March 20, 1883.

Digitized by Google

now, however, equally divided between the circuits I-II and II-III, connected as shown. If the resistance of the 6 odd-numbered lamps, 1-11, exactly equals that of the 6

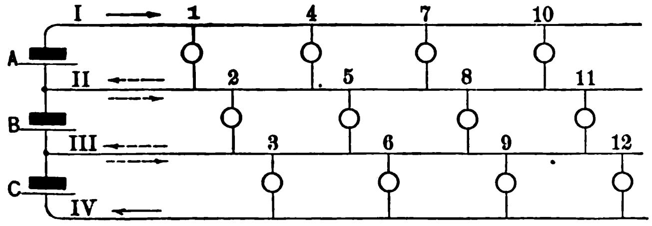


THREE-WIRE SYSTEM.

even-numbered, 2-12, and if A and B keep up the same difference of potential, no current will flow in II, between the dynamos and where the first lamp joins it. Suppose II to be cut, there will then be a single circuit through A and B, I and III, and the 12 lamps, as shown, with a difference of 200 volts in I and III. The resistance of the 12 lamps, as now arranged, will be four times what it was before, and hence only one-half as much current will flow through I and III. But each of the lamps will get just as much as before, and will shine the same. The conductors I and III, since the resistance is now four times as great, need only be one-fourth as heavy, according to our adopted principle. This is also proper as regards heating-effect in them, which, proportional to the square of the current, is now only one-fourth what it was before.

If this were all that was needed, we should now have the same amount of lighting done, and the conducting mains, which are the most expensive part of the plant, of only one-fourth their size and cost in the two-wire system, and with only the additional expense of another dynamo. Moreover, since the current is only one-half as much, these two dynamos, though giving the same potential as before, can be smaller. But on account of the difficulty in keeping an exact balance in the two sets of lamps, especially about the time of lighting up at twilight, it is necessary to introduce the third conductor from between the two dynamos, and then neither circuit can be exposed to a difference of potential greater than either dynamo is generating. Also, if the balance is not kept, a current through II, and a galvanometer, shows on which side the lamp resistance or the dynamo potential is in excess; and Edison restores the balance by variable resistances in the circuits of the field magnets, or, in some cases, by bringing an extra conductor from one or two large buildings, like factories, theatres, etc., when near by, so that they can, at will, be thrown into either circuit from the central station.

This middle wire need not, for most purposes, be so large as the other two; but, in the case of a breakdown of I or III, it will have to do equal work with the other, so that it is safer, simpler, and better to make them all of the same size. The cost, then, of conductors, is that of three wires, each of one-fourth the section of the two in the first case, or $\frac{3}{2} \times \frac{1}{4} = .375$, or a saving of 62.5 per cent.



FOUR-WIRE SYSTEM.

The four-wire system shows a still further reduction of expense. The law on which this percentage of economy proceeds, as far as cost of conductors is concerned, may be shown as follows, in units of the cost of the two-wire system:

For 2 wires, we have,	$\frac{2}{2}(\frac{1}{1})^2$	1.000
" 3 " " "	$\frac{3}{2}(\frac{1}{2})^2$	.375
" 4 " " "	$\frac{4}{2}(\frac{1}{3})^2$	.222
For 5 wires, we have,	$\frac{5}{2}(\frac{1}{4})^2$	.156
" 6 " " "	$\frac{6}{2}(\frac{1}{5})^2$	.120

A limit of economy or practicability, however, will soon be reached in the increased number of dynamos, the complexity of the system, and especially in keeping up an approximate balance between so many circuits. In practice, probably, the three-wire system, with its saving of .625 of the cost of the two-wire, will be found all-sufficient; except, perhaps, in the case of a long main through a large scattering district, when the four or five-wire plan might be preferable.

One other advantage, available in all these systems over the two-wire plan, is, that if needed for purposes of driving motors, or for large street lamps of higher resistance, a potential twice as high as the ordinary one is very simply available by connecting across from I to III, or three times as high from I to IV in the four-wire plan, etc.; and, no matter what the amount of such employment, it will not disturb the balance of the intermediate lower potential circuits.

In a recent number of the *American Engineer*,[3] Professor H. S. Carhart, referring to the Edison three-wire system, says: "It is evident that this arrangement does not secure the maximum economy corresponding to the results obtained for the most economical size of a conductor. . . . . In the arrangement adopted by Edison, the ratio between the energy consumed by the lamps and that wasted in the conductors remains the same as in the two-wire system, the two classes of resistance being increased four-fold each. The additional running expense due to heat waste in the conductors is not diminished in the least, while the cost of the conductors is diminished to three-eighths the former amount. If the principle is a good one that the most economical size of a conductor is attained when the loss by heating it equals the interest on its first cost, then clearly such a condition is not realized in the three-wire system, provided it is applied in determining the size of conductors in the old two-wire plan. The current being reduced 50 per cent., the size of the conductors should be reduced only the same fractional part. The E. M. F. required to maintain the current would then be less than 2E. In other words, the two dynamos could then be made smaller and could furnish a somewhat lower E. M. F. In the two-wire system the equation for the current gives $E = Cr + C R$, in which

E = difference of potential maintained by the generator between the two adjacent mains.
r = the joint resistance of all the lamps in multiple arc.
R = resistance of mains, and
C = current in mains.

If the size of the conductors were reduced only one-half, we should have

$$\frac{1}{2} C = \frac{2E}{4r + 2R}$$

Whence $E = Cr + \frac{1}{2} CR$ for the E. M. F. of each dynamo. So arranged, the three-wire system would secure a gain of 25 per cent. in cost of conductors, and a further gain in reduction of running expenses. This gain is readily estimated. The energy expended in the three-wire system with conductors reduced three-fourths in size is

$$\frac{1}{2} C \times 2E = C\ (Cr + CR) = C^2r + C^2R,$$

of which the first term is the energy spent upon the lamps, and the second denotes the waste upon the conductors. The energy expended with conductors reduced one-half in size is:

$$\frac{1}{2} C \times 2E = C\ (Cr + \frac{1}{2} CR) = C^2r + \frac{1}{2} C^2R.$$

From this it appears that the energy absorbed by the lamps is the same as before, while the energy wasted in

3. See also Prof. Cahart in *Science* iv. p. 477.

Digitized by Google

the conductors is reduced to one-half its value in either of the other plans. The three-wire system, as arranged by Edison, permits of a saving of the interest on 62.5 per cent. of the cost of the copper conductor. A three-wire system with a reduction of one-half in the size of the conductors, allows a reduction of interest on 25 per cent. of the cost of conductors, and 50 per cent. of the running expenses due to heat waste, or a total of 75 per cent. of the interest on cost of conductors, a gain of 12.5 per cent. A further advantage to be derived from the reduction of the conductors to only half their original size, as compared with the reduction to one-fourth, is the lower temperature to which they will be exposed. With conductors reduced one-half in sectional area, the energy expended upon them, and therefore the heat developed, are only half the amount involved in either of the other arrangements; the thermal capacity of the wire being also half as great as in the two-wire system, the rise of temperature will be just the same. But if the conductors are reduced to one-fourth their original dimensions, while the quantity of heat generated in them remains the same, the rise of temperature will be four times as great as the two-wire plan.

We submit the question then, whether Mr. Edison has not sacrificed a portion of the advantage legitimately belonging to his device by attempting too great a saving in the cost of conductors."

In reply to the criticism of Professor Carhart, the author of the original article[4], while admitting the justice of his correction, suggests that Professor Carhart has not reached the most economical result "for the reason that we have the interest on n conductors, but heat developed in only 2 of them." He proceeds to develop the solution of the problem mathematically, by assuming the size of the conductors in the 2-wire system to be such that the interest on their cost equals the cost of the heat-energy developed in them, from which he deduces the following table of comparative results :—

EDISON'S SYSTEM.

No. of Conductors.	Cross Section of each.	Difference of potential at terminals of each dynamo.	Interest on conductors.	Heat-waste in conductors.	Running expense of conductors.
2	1.000	1.000 $CR + Cr$.	1.000	1.000	2.000
3	0.250	1.000 " "	0.375	1.000	1.250

4. *Science*, v. p. 23.

In conclusion he says :—"Some very interesting comparisons of relative advantages might be noted, did space permit. The most important is the rapid increase in the ratio of heat energy to capacity of conductor in the Edison system, which might make it necessary to lay the wires so as to admit of pretty free radiation of heat.

"This question of temperature of electric-lighting conductors promises to protrude itself the more they are laid underground. The desideratum for an insulating covering would seem to be a non-conductor of electricity and good conductor of heat, apparently inconsistent qualities. Perhaps the eventual solution will be in bare or loosely covered wires on highly insulated points of support, thus admitting of free radiation of heat, like aerial lines."

THE ECONOMY OF ELECTRIC LOCOMOTION.

A WRITER in the *American Engineer* criticizes the estimate and calculations of Professor Farmer,[1] in reference to the cost of operating the elevated railroads in New York city by electricity. He says:—

Notwithstanding the high authority of Professor Farmer, we must express our conviction that these estimates are entirely too favorable. The total estimated saving is based on the higher efficiency of the large stationary engines and the cheaper coal used to generate steam. The weight of coal used by the stationary engine is estimated at 35 per cent. of the amount required by the 20 locomotives, at 1¾ and five pounds of coal per h. p. per hour respectively; and the coal of the central station is assumed to cost only ⅝ as much as the locomotive coal. The cost of coal for the central station would then be ⅝ of 35, or 22. per cent of present cost, a saving of 78 per cent. for the same power developed by the steam engines. This is undoubtedly too large; for while a steam engine developing 1 h. p. with 1¾ lbs. of best coal per hour are in use, yet so high an efficiency as that can hardly be expected of stationary engines in general, especially if they burn coal costing only $2.50 a ton. Further, the margin between this 78 per cent. and the percentages expressing savings in the fourth column of the table is very small. This margin must cover all losses whatsoever in transmission. It is to be noted, however, that the losses are to be estimated on the basis of loss of the cheap power of the large stationary engines and not of the comparatively dear power of the locomotives. Still it is difficult to see how Professor Farmer has reached such conclusions. He has perhaps wisely refrained from giving us any of his processes.

One difficulty with all these rose-colored estimates appears to be the entire failure to apprehend the difference between the intrinsic efficiency of a dynamo or a motor, and the efficiency of an arrangement consisting of a generator, connected by a conductor to a motor, for the purpose of transporting power. The intrinsic efficiency refers merely to the heat-waste in friction and internal induced currents. If the output of the generator is measured electrically and the E. M. F. measured is the difference of potential between the two binding posts leading to the machine, then the intrinsic efficiency would cover also the power consumed in maintaining the field magnets. We very much doubt if the dynamo has yet been constructed of such superior character that 10 per cent. of the mechanical power applied to it will cover loss in friction, fugitive currents, and maintenance of field magnets. We say nothing about armature resistance, though that will be very considerable in high E. M. F. machines.

But the efficiency of a combined generator and motor for transport of power depends not only on the efficiency of these machines *per se*, but also on the counter electromotive force furnished by the motor and on the resistance of the conductors. When power is transmitted from one machine to the other at the *maximum rate*, only 50 per cent. could

1. This Journal, vol. iv., p. 21.

Digitized by Google

be recovered on the hypothesis that both machines are "perfect" electrical engines. If a higher return than this is desired then the motor must run under a lighter load, power must be transmitted more slowly, and the current must be correspondingly diminished.

The 20 locomotives on the Second avenue line are assumed to represent 2200 h. p. Other reports rate each engine at 40 h. p. But keeping to Professor Farmer's basis, this power in watts, or ampère-volts, is $2200 \times 746 = 1,641,200$. But as this is 90 per cent. of the power reaching the motors we have to supply 1,823,500 watts for absorption by them, or in round numbers, 1,800,000. If the twenty trains are supposed uniformly distributed over the 6.5 miles of track, and the generating station is placed at the middle, the average resistance of the middle rail is about 0.048 of an ohm, counting the resistance of the rail 0.05 ohm to the mile. The resistance of the return rail would be 620,024 ohm, making a total of 0.072 ohm in the rails. This is undoubtedly too small, because of the connections that have to be made from rail to rail. The resistance might be as low as this if the track and conductor were one continuous rail. Admitting that the resistance may be made as low as 0.072 ohm, and that the loss of 10 per cent. in dynamos and motors covers maintenance of field magnets and armature heat-waste, we can readily calculate the following table for a final recovery of 1,800,000 watts corresponding to 2171 h. p.

Current in ampères.	E. M. F. of generators.	E. M. F. of motors.	Effective E. M. F. difference.	H. P. lost in heat.	H. P. on circuit.	H. P. applied.	Per cent of expense saved.
5000	720	360	360	2412	4824	5360	45.9
4000	738	450	288	1544	3956	4395	55.6
3000	816	600	216	868	3280	3644	63.0
2000	1044	900	144	886	2798	3109	68.5

This table may be verified in the following manner: Energy in watts is the product of the current in ampères and the E. M. F. in volts. The product of the current and the E. M. F. of the motor, in each case, is 1,800,000 watts or 2412 h. p. nearly; and 90 per cent. of 2412 is 2171. The heat-waste may be estimated in the same way as the product of the current and the corresponding "effective E. M. F.", or as the product of the resistance and the square of the current. Thus

$$(4000 \times 288) \div 746 = 1544 \text{ h. p. or}$$

$$(4000^2 \times 0.072) \div 746 = 1544 \text{ h. p.}$$

We may find similarly the total h. p. equivalent of the electrical energy, or we may find it by adding the heat-waste in each case to 2412. Remembering that the electrical energy of the generator is only 90 per cent of the power applied, we obtain this latter readily for column seven. The final column is obtained by finding the ratio between the power applied and 2171 or the power recovered, multiplying 22 per cent. by this ratio and substracting the product from 100. If the coal cost more or the stationary engine is less efficient, the saving will of course be less for a double reason. With a current of 5000 ampères more power is wasted than is recovered—3189 h. p. lost to 2171 returned. The same is true with 4000 ampères. But still the total cost of this power, on the basis of the assumptions made, is only 54.1 per cent. in the one case, and 44.4 per cent in the other, of what must be expended by locomotives to produce 2171 h. p. per hour.

If the stationary engine consumes 2.5 pounds of coal per h. p. per hour, then the estimated savings will be reduced to 23.7, 37.4, 47.9, and 55.7 per cent. respectively. It is easy to see, therefore, that the estimated saving in coal is very precarious.

We may show also incidentally that limits are set to the E. M. F. that can be used when we determine the power to be absorbed by the motor and the resistance of the line. If E and E_1 are the E. M. F, of generator and motor respectively, taken as the difference of potential between the binding posts of each machine, R the resistance, and W the power absorbed by the motor, then we have

$$E_1 \, C = \frac{E_1 \, (E - E_1)}{R} = W = \text{a constant.}$$

If W and R are both constants then $E_1 \, (E - E_1)$ is also a constant. When the product of two numbers is given their sum is a minimum when they are equal to each other. The sum of E_1 and $E - E_1$ is E, the E. M. F. of the generator. In the case before us E_1 equals $E - E_1$ when each is 360 volts. Hence the minimum E. M. F. of the generator or difference of potential between its binding posts is 720 volts. Similarly an upper limit is established by the ratio of the counter to the direct E. M. F. In the present problem with a current of 2000 ampères, the counter E. M. F. is 86.2 per cent. of the direct. That is probably higher than is now attained in practice, and would correspond, in this case, to a direct E. M. F. of 1044 volts. The E. M. F. to be employed under the assumed conditions, would lie somewhere between 720 and 1000 volts, probably nearer the former than the latter. It is then easy to see on what doubtful grounds such estimates of savings as those of Professor Farmer are made. The percentages of savings in the last table are lower than his, but they are still undoubtedly too high, because of the assumed high efficiency of the stationary engines, the extremely low resistance of the electric circuit, and the minimum allowance made for losses in the dynamos themselves. When, however, we add to the possible saving in the full, the reduced expenses referable to other items, such as dispensing with skilled labor of locomotive engineers and the smaller loss from depreciation of rolling stock, it is evident that the faith of the foremost electricians in the entire feasibility of operating elevated roads by electricity is well founded.

ELECTRIC LIGHTING IN AMERICA.

The following is an abstract of a paper with the above title, read before the Society of Arts, London, by W. H. Preece, F. R. S., after his return from an extended trip in this country:

Electric lighting flourishes in America much more than in England. There are probably 90,000 arc lamps alight every night in the states, and there are many central stations working regularly, both with arc and with incandescent lamps. Contrasting the brilliantly illuminated avenues of New York with the dull and dark streets of London, Mr. Preece states that on the evening of October 21 he drove from the Windsor Hotel, New York, to the Cunard wharf, a distance of about 4 miles, through streets entirely lighted by electricity. On October 30 he drove from Euston to Waterloo without seeing a single electric light.

Mr. Preece visited Montreal, Philadelphia, Buffalo, Cleveland, Chicago, St. Louis, Indianapolis, Boston and New York, and found in each city the principal streets and warehouses, as well as stores and places of public resort, lighted by arc lamps. With arc lighting the greatest advances have been made in the states. One manufacturer turns out as many as 800,000 carbons for arc lamps per month; another says that his output of plant is 50 arc lamps and 3 dynamos per day; and while present at a third factory, Mr. Preece mentions an order was received for an electric lighting plant of 330 arc lamps, requiring 14 24-light dynamo machines, intended for an installation to light up a park in the environs of Chicago. In that city the number of arc lamps installed has doubled, increasing from 1,000 to 2,000 during the past 12 months. More than one electric light company pays dividends to its shareholders, and all the manufacturers, as well as the lighting companies, seem to be full of work.

The principal systems in use are, for arc lamps, the

Digitized by Google

Brush, the Weston, and the Thomson-Houston; but there are other arc systems, not so well known on this side of the Atlantic, such as the Hochhausen, the Van de Poele, the Western Electric, the Fuller, the Sperry, etc.; for glow lamps, the Edison and the Weston. Visiting central stations in various towns, Mr. Preece found 164 Thomson-Houston arc lamps alight in the public streets and shops in Montreal. The rate of payment was 50c. per lamp per night from dark to midnight, or over £35 per lamp per annum. At Philadelphia the Brush system, employing 1,200 h. p., supplies electricity for nearly 1,000 lamps, for which £60 per lamp per annum is charged. The Brush people have also two central stations at Boston, lighting up 816 arc lamps; in fact, there are few towns of any consequence in the states that do not possess central stations worked by the Brush company, and probably there are 25,000 Brush arc lamps in use in the United States.

At Chicago all the drives in the Lincoln Park are lighted by arc lamps with very good effect, especially on the unique drive skirting the shore of Lake Michigan. Other companies also have central stations in Chicago. The lecturer did not see in the states one single instance of street lighting by glow lamps. In every case arc lamps were used for this purpose, and they were usually fixed on much taller posts than in England. Although brilliant, the effect was by no means perfect, and no effort seemed to be made to distribute the light uniformly, as had been done in England by Mr. Trotter. The price paid in New York is 70c. per night, or £50 per annum, for each arc lamp; but a fine of about 6s. for each time any lamp is reported out is inflicted.

As regards incandescent lighting, it does not seem to flourish so much as arc lighting, nor, indeed, has it been applied to private houses to the same extent as in England. The principal system of incandescence in practical use is that of Edison. House lighting has been attacked principally by the Edison company. They have a central station in New York, which was opened on September 3, 1882, and from that date to the time of Mr. Preece's visit there had been only two hours and a half stoppage, and that due solely to carelessness. There are 587 subscribers, using altogether 12,764 lamps, served day and night. The price charged is the same as that which would be paid if gas were supplied at 7s. 6d. per 1,000 cubic feet, whilst the price of gas has now been reduced to 5s. 9d. The use of secondary batteries has not received so much attention as on this side of the water.

No difficulty is found in determining by the Edison meters the charge to be made, the subscribers paying for the light they receive, and not for the current they use. These bottle measurements are unquestionably accurate within 1 per cent.

Mr. Preece sums up the results of his investigations in the following statement of the general commercial position :

The problem as to whether electric lighting is practical, and as to whether that means of illumination can be made to pay, has been thoroughly solved in the United States. The great mistake that has been made there, as it has been made here, has been the attempt to enter into competition with gas. The Edison company started on the basis of the charges made for gas, and the result of the two years' working has been to show that this was a financial mistake. Electricity must earn its future success entirely upon its merits, and not on its economy. In the case of street lighting it has proved itself to be a good thing, and if once a thing is proved to be good in America, it is immediately taken up. "Progress," in that country, is the word. Novelty is a certain criterion for consideration. Manufacturers do not hesitate to clear out their entire factory, if they find that they can get cheaper and better work by entire renewal. So with the electric light. If it proves itself (as it unquestionably does) to be a better light than gas, then gas fittings will be instantly removed, and electric light fittings substituted, without particular reference to the cost, so long as it is reasonable and within the means of the consumer.

I have said, more than once, that at the present day we can only regard the electric light in England as a luxury, and we must pay for it as a luxury. But there is no reason why it should always remain a luxury. There are various chances of economy which justify the conclusion that, sooner or later, the price will be brought down so as to relieve us of the use of the term luxury as applied to it. For instance, the output of the dynamo can be extended, as has already been done with several types, particularly, as I have pointed out, in the case of the Brush pattern, where 60 arc lamps are now lighted where only 40 lamps were supplied by the earlier and unimproved machine.

Again, considerable reduction in the weight, and therefore in the cost, of the conductors has been obtained by the production of the 3-wire system. Moreover, when existing patent rights lapse, the manufacture of dynamos will become general, and the consequent competition will, no doubt, result in the production of efficient machines at a sum far below the cost of those made under existing patent rights.

The efficiency of the glow lamps has also been very considerably affected by the improvements made, for instance, by Messrs. Woodhouse and Rawson, and by Mr. Bernstein. The efficiency of the Edison lamps means the consumption of energy at the rate of 5 watts per candle, but lamps are now being made which give an efficiency of 2.5 watts per candle, with an equal life, which is equivalent to an immediate reduction of 50 per cent. in the amount of energy required to maintain the system alight, and, therefore, in the cost of its production.

There is still vast room for economy, and it is quite clear that the prices which are now necessary to make electric lighting pay, must not be regarded as final; they will be brought down.

Even now it is possible, in England, to make a system pay at the rate of a halfpenny per glow lamp per hour; and no one who has ever experienced the charm and comfort of the electric light, and who has electricity brought to his door, and supplied to him at this rate, would hesitate to pay that figure for the use of electric lamps, although he could obtain the same light by gas at less than half the price.

There is a point that will lead to the introduction of the electric light that is very marked in the United States, viz., its influence, when applied to the streets, upon the morality and safety of the public.

The chief of the police of New York has gone so far as to say that "every electric light erected means a policeman removed." This, though probably not true as regards actual numbers, is so far true in fact, that the supervision of the streets and thoroughfares is rendered far simpler when they are brilliantly illuminated by the electric light. Its moral effect is principally to be noticed by the way in which it has checked the formation of crowds, and disturbed the haunts of those who, unfortunately, infest most great towns and cities, and who render the streets of London at night a disgrace to modern civilization.

An interesting discussion of Mr. Preece's paper was then participated in by other members present.

Mr. Hammond said it was not his privilege to go to America with the British Association, but he was there last year, and did not keep so much to the east as Mr. Preece had done. After leaving Chicago, he again found the electric light at Denver, in Colorado, in Salt Lake City, and in San Francisco, where he found, perhaps, the finest hotel in the world lighted throughout by electricity. The Americans, therefore, had gone much farther ahead than we had, but it was very desirable to draw the correct lessons from what was to be seen there. They were sometimes told that the English were very slow, but it was not entirely due to want of enterprise that in this matter we were behind the states. One great point was the price of

Digitized by Google

gas, which was much dearer in America than in England. Again, many of these contracts in America, though they might not involve any loss, did not show any profit. In order to get sole control of a town, the municipality had in some way to be accommodated, and this was done by supplying them with the electric light at 50 cents per night; but it would not pay even here to supply an arc light of 2,000 candles at £35 per annum; at any rate, if you did not lose, you would make nothing by it. There were many cases where the price was double and treble, and where good profits were being made, but it was in localities like Salt Lake City, where people had plenty of money to spend, and where gas was about 17s. a thousand, that the best place for the electrical engineer was to be found. In some places in the west they had no light at all, and would have given anything for the electric light. Again, the Americans were very enterprising in business; they worshipped the almighty dollar, and looked upon the electric light as a good advertisement. A man would, for the sake of outshining his rival, put the most flickering arc light outside his door, and his experience was that the American arc lights were far behind our own. Again, the heat there was very great, and whilst in England some people liked the warmth of gas, in America no one would go to a hotel not lighted by electricity, if there were one opposite which was. It was, however, used simply for business, and was an advertisement. The man who would have it in his store would not think of using it at home to make it more comfortable, because it cost too much. Gradually, however, some of the leading Americans were introducing it for domestic purposes; but when he was in New York, Mr. Edison had not got it in his new house, and Mr. Brush had not got it in his in Cleveland. It was remarkable to see the effect the overhead wires had had on Professor Forbes. An Englishman in New York would think London a peaceful village in comparison. There was a railway overhead, the passengers on which could converse with the people at the first floor windows along the route, and there were these posts with 60 and 70 wires on them all along the principal streets; in 5th avenue they were worse than anywhere. He did not mind them himself, but they must not regard this matter simply from the point of view of those who lived by electric lighting, and he was sure such things would not be tolerated in England. There was no Board of Trade in America, but he was sure they would find it better eventually to put the wires underground, when the system was firmly established. But directly they wanted to put them underground in England, they had to apply to Parliament for permission; in America it was only necessary to find out the man who represented the municipality, and the matter was easily arranged over a long drink at the bar. That was local option; but in England they had to go to Parliament. As they urged on Mr. Chamberlain, the other day, why should not the local authorities be empowered to grant liberty to any company, in whom they had confidence, to put wires underground? It was a mere accident of their industry that they had to deliver electricity by wires; if they could deliver it like other wares, by van, they would not need to ask Parliament anything about it; but because they had to use wires, a delay of some 18 months, and all kinds of difficulties, stood in their way. The great lesson to be learned from America was that it could be done. There were hundreds and thousands of people ready to pay double the price of gas for the electric light, but capitalists were constantly saying they were told it could not be done. Mr. Edison had shown in New York that incandescent lighting could be supplied from a central station, and that when done on a large scale, the risk of failure was infinitesimal. In New York they were able to make a small margin of 3 per cent., using 5 watts per candle, getting 7s. 9d. for it, and paying $\frac{4}{5}$ths for the manufacture. In England it could be produced with 3 watts per candle, at a cost for manufacture of 3s. 8d., instead of 6s. All the installations in America had been made in one way, taking the current direct into the houses. A reference had been made to storage batteries, but in no case had they yet been used as a part of a general system, as we hoped would soon be introduced in London, and with a much less capital outlay. If in New York they could make 3 per cent. on a capital of £200,000, which included an immense amount sunk in experiments, they might hope, in England, to make 8 per cent. on a capital of £70,000, which would be sufficient, with proper plant, and the advantage of further experience; and by working at 3-5ths the cost, they might even hope to make 12 per cent.

ELECTRIC LIGHTING FOR RAILWAY COACHES.

Considerable attention has been devoted in England to the lighting of railway trains by electricity, but there are many obstacles to overcome, and it is doubtful whether any of the various plans devised can yet be considered thoroughly successful. The London *Electrical Review* publishes the following comments upon the different systems which have been proposed or tested :—

"In the *Electrical Review* for January 12th of last year we commented at some length upon two systems which had been brought forward for providing our railway carriages with an effective light by the application of electricity. One method was that of employing a dynamo and driving engine combined and carried by the locomotive, the boiler of the latter supplying steam; the other consisted of a combination of dynamo and accumulators, the generator of the electric current being driven by means of belting from the axle of part of the rolling stock.

"We stated at the time that anything electrical in connection with railway operations should be of the most simple nature, and that we should therefore be inclined to place most confidence in that system which apparently offered the least chance of failure. It is therefore not a little gratifying to find our views generally supported by such well-known men as Messrs. W. H. Massey, Gisbert Kapp and R. E. Crompton, although we must, in justice to the advocates of the accumulator system, admit that Messrs. Stroudley and Houghton have been most successful in the application of the dynamo-accumulator combination. In the method first mentioned the objection that the lights are extinguished whenever it may be necessary to uncouple the locomotive engine which carries the dynamo was naturally raised. Mr. Massey meets this by remarking that such a contingency ought not to weigh with those who know from experience that it makes little or no difference in well-lighted stations whether the carriage lamps are lighted or not. This argument is ingenious, but fails from the fact that we do not yet possess the well-lighted stations which would diffuse sufficient illumination through any carriages there standing. Mr. Kapp goes further and makes a practical suggestion for meeting the difficulty. This gentleman, in the correspondence columns of a contemporary, says there is no reason whatever why the lights should be extinguished for a single instant, although the train might be left standing without its locomotive for any length of time. All that would be required would be a dynamo fixed in the station where the trains are made up and the provision at suitable places along the platforms of flexible twin cables in connection with the main leads from the dynamo. Some of the coaches in each train, or preferably all the coaches, should be provided with terminals connected to the main leads throughout the train, which would fit a clip attached to the end of each pair of flexibles. To prevent reversal of polarity the clip should be so arranged that it would only go on one way, and the flexibles might be stowed away under the edge of the platform in the same way as are the India-rubber gas pipes in Broad street and other stations.

"Immediately a train comes in the nearest flexible would be clipped on to any of the terminals within reach, and for

Digitized by Google

the time being the train would be lighted jointly from the dynamo on the locomotive and from that fixed in the station. After detaching the locomotive, the station dynamo would continue to light the train until a new locomotive was coupled on. The dynamo in the station, with its engine, leads, flexibles and clips, would be far cheaper, thinks Mr. Kapp, than a set of accumulators for every train, and would also have the additional advantage of serving at the same time for the permanent lighting of the station. Mr. Crompton adds:—'I would call attention to the self-evident fact that electric lighting mechanism does not differ from other mechanism, in that trustworthiness and efficiency go hand in hand with simplicity and few parts. Again, although no prominent mention has hitherto been made of the fact, there is absolutely no comparison between the cost of direct running and of the van dynamo-accumulator system, the cost of the latter, whether for first cost or for maintenance, being quite double that of the former.'

"It appears, then, that the three gentlemen whose opinions we have quoted are all in favor of electric lighting being carried out without the addition of secondary batteries to the plant. The suggestion of Mr. Kapp is a novel one, but there are, we think, grave difficulties in the way of practically carrying out the scheme.

"We imagine that in many instances there are stations in which trains are made up, or, at all events, where carriages are taken on and off, so unimportant in themselves as not to warrant the adoption of a dynamo and engine for permanently lighting the usual offices and platforms. There would again be considerable difficulty in preventing short circuiting or leakage from a set of flexible leads when used and stowed away in the manner of India-rubber gas pipes, and the probabilities are that the station itself would frequently be left in darkness from such causes. Nevertheless Mr. Kapp's idea is one which, for special cases, we are inclined to think worthy of a trial. The great advantage possessed by the present modes of lighting railway carriages is, especially so far as oil lamps are concerned, that each carriage is independent of its neighbors. In cases of a breakdown, or of more serious disasters, this is a desideratum, the importance of which can scarcely be over estimated. Whether this will ever be accomplished by means of electric lighting remains to be seen; if so, it certainly will not be by the method of supply upon which we have just commented. Secondary batteries are being improved, and their weight, for producing a given effect, much reduced, and we can yet conceive each carriage supplied with three or four cells to work a low resistance incandescent lamp so as to render each car independent of the rest. Such a scheme would, of course, necessitate the provision of charging stations, but if tram cars are to be propelled and lighted by the means pointed out by us a fortnight ago, and Mr. Reckenzaun's recent experiments appear to point to such a happy result, what is to prevent the latter application, eventually, to railway trains?

"Improvements in nearly all branches of the applications of electricity have been so rapid and important that it is rather venturesome in the present day to give decided opinions on any matter which is not already well established. We will, therefore, only add that we trust the new year will provide abundant opportunities for the fair and impartial trials of every system which promises good and lasting results."

ELECTRICITY FOR STREET RAILWAYS.

Among the special committees appointed at a convention of the American Street Railway Association, was one which was to report on "Electricity as a Motor for Railroad Transportation." The facts elicited, although not wholly new to our readers, show that attention is being generally directed to the subject. The report as given herewith is from the *American Railroad Journal:*

The Committee on Electricity as a Motor for Railroad Transportation is not prepared to make a report from personal inspection; but from the information received from different sources, they feel justified in reporting the possibilities of the new system to be very flattering. The experiments made in different places demonstrate beyond question its safety and practicability; and it will not be long before the question of economy will be fully determined by the experiments at Cleveland. In this country and in Europe, there are now several electric railroads in successful operation. The Litchterfelde road, in Berlin, has been for 4 years a financial success, and the results of the experiments at Coney Island, Menlo Park, and by Messrs. Daft and Edison, at the Mechanics' Fair building at Boston, Mass., have thus far been very satisfactory and encouraging. I herewith submit for your consideration the enclosed communication of Mr. W. H. Knight, of the Brush Electric Company, of Cleveland, Ohio, giving the result of the Cleveland experiment in detail. This letter, coming as it does, direct from the operator of the street railroad at Cleveland, in response to a request from this committee soliciting such information as would be valuable and interesting to the convention, is really the sum and substance of this report, and contains all the reliable information before this committee.

As chairman of the committee I confess that I have not given to the investigation of this question as much of my attention as its importance demanded; but the unusual pressure of official duties during the last 6 months has occupied all my time.

Ed. C. Peters, *Chairman.*

Brush Electric Company, Cleveland, O.,
October 8, 1884.

E. C. Peters, Esq., *Chairman Committee on Electricity as a Motive Power of the American Street Railway Association.*

Dear Sir,—Your favor of the 30th ult. is at hand, and contents noted.

The electric railway which we are now operating here is about one mile in length, and at present only one car is run on it. The second car will soon be completed, and the line will then be extended across the railway tracks to a distance of about one and a-half miles. This section, with its 2 cars will be operated all winter without intermission, to demonstrate the "rough and ready" character of the motor, after which the system will be extended over the 20 miles of tramway owned by the East Cleveland company. Last winter we operated a trial railway, built in the yard of these works; and as it stood the tests of all kinds of weather, we have no doubt in our own minds as to its efficiency the year round. Briefly the system may be described as follows:

Midway between the rails a conduit 8 inches deep is laid flush with the pavement, in the manner of a cable road. Two iron rails serving as conductors are supported within this conduit, and through a slot five-eighths of an inch wide in the top of the conduit, a plow depends from the car, and by means of 2 brushes makes contact with the conductors. Through this plow the current is conveyed to the motor, which is situated between the wheels under the car, and is tightly boxed up to prevent access of dust, etc. The motor weighs half a ton, and the car is an ordinary 2-horse box car, weighing, exclusive of motor, 2 tons. The motor is geared to the axles of the car by friction gear and link-belts. The movement is controlled by levers at either end of the car, these levers operating the commutator brushes on the motor to start, stop, or reverse the motor, or to make it go at any speed desired. It has been run at a speed of 15 miles an hour.

The dynamo supplying the current is located about a mile from the line, and is run by the engine used by the company for grinding corn. It is connected to the conduit by an over-head line of No. 8 wire. In practice, no over-head line will be used, and a greater economy may be anticipated. The power is sufficient to run 2 cars, as the engine and dynamo after being started in the morning, runs all day without attention. Only one man is employed to do the firing, and the expense of power, including fireman, coal and oil is about 4 dollars per day. With a larger plant, larger and more economical engines, boilers and dynamos would be used, and a much greater economy obtained.

The conduit will cost from five to seven thousand dollars a mile when made of steel, and it ought to last a lifetime. To equip an ordinary 2-horse car will cost in the neighborhood of $1,500, and the power at the central station for each such car will be in the neighborhood of $1,200. Each car will pull another car of the same size. The steepest grade we have experimented with is 500 feet to the mile, and no difficulty was found in overcoming it. The conduit is kept free from dirt, snow, etc., by a brush depending from the car through the slot. Catch-basins are placed at intervals varying from 50 to 100 feet, and where possible a sewer connection is made. The system is similar to a cable road in that it requires a conduit and a central power station; but it differs in every other respect.

It may be operated on single tracks as well as on double tracks; and branches may run out from the main road in every conceivable manner. Any speed may be assumed at the will of the operator without wear of machinery. Ordinary car-drivers

Digitized by Google

can operate it after five minutes' instruction. Stoppages can be made quickly by reversing the motor. Running off the track does not injure the machinery, and a flexible connection on every car enables the motor to run the car back on to the track when the lever is reversed. A much smaller conduit can be used than with cables, and there is no machinery along the line. The conductors cost but $200 a mile, and the wear of the brushes upon them seems to be *nil*.

We use a high tension current because our investigations have showed us that when distances greater than 1 or 2 miles are to be overcome, no other current will give the necessary economy. The conductors are, however, inaccessible, and no danger is anticipated. We are ready to equip any road not exceeding 25 miles in length.

Hoping I have touched upon the main points of interest,

I am, very truly yours,
W. H. KNIGHT.

LITERATURE.

REVIEWS.

Illustrations and Descriptions of Telegraphic Apparatus. By ASTLEY C. TERRY and WILLIAM FINN. Buffalo: A. C. Terry, 1884.

THE plan of this work is essentially different from that of most others of the kind. It consists principally of a series of theoretical diagrams embracing all the different systems of apparatus now used in American telegraphy, which are consecutively arranged in the volume and accompanied with the necessary explanatory text. There are in all some 30 full-page plates, and these are not only skillfully and artistically designed, but have been executed with the highest skill of the engraver's art. As we have intimated, the plan adopted by the authors is not that of a consecutive treatise, but rather that of a book of reference, and it is apparently designed more particularly for the use of wire-chiefs, office managers and the higher grade of telegraphic operators who are supposed to be already conversant with the ordinary apparatus which of late years has come to be known distinctively as the "plain Morse." Among the minor subjects illustrated and explained are switch-boards, special arrangements for small stations for working either a sounder and register from one relay, a sounder on either one of two relays and the like. The different forms of repeaters in practical use are all given, among others Neilson's shunt repeater, an invention largely used in Canada of which we do not remember to have seen a description elsewhere. The duplex and quadruplex apparatuses with the various modifications necessary to adapt them to use under different conditions of service, are given with much completeness and attention to detail. The Wheatstone automatic duplex system with its special form of repeater is very carefully described and illustrated, and also the universal Gold and Stock printing telegraph system and Gray's multiplex harmonic apparatus. A chapter on line testing and measurement both with the tangent galvanometer and Wheatstone bridge is given, which is profusely illustrated and accompanied with explicit and carefully prepared instructions.

The excellencies of this work are numerous and its faults are few. The descriptive text is concise, and well prepared, and we notice no errors or omissions of particular importance. The polar duplex with battery at one station only, should have been credited to Edison, it having been invented by him in 1872 or 3, and having in fact constituted his original conception of the method of simultaneous transmission by changes of polarity and changes of strength in the current, upon which the quadruplex was afterwards founded.

It is impossible to speak in too high praise of the mechanical execution of the work. We have already mentioned the excellence of the illustrations, and it is only necessary to add that the typography, printing and paper are of equally high quality and reflect the utmost credit upon the taste and skill of the printers and engravers, Messrs. Matthews, Northrup & Co., of Buffalo. We observe however one fault in the make-up of the volume which might have been avoided by a little ingenuity, namely, that the text referring to a particular illustration often appears on the page facing some other illustration, which is not only an exceedingly inconvenient arrangement but is in some cases liable to cause confusion. The insertion of a few additional pages would have remedied the difficulty and the surplus space might with advantage been utilized for tables or other information frequently required in making tests.

Every telegraph operator who is ambitious to excel in his business, will find this work of very great assistance to him, while as a work of reference, it will be found indispensable in every telegraph office.

The Fireman's Guide; a Hand-Book on the Care of Boilers. By KARL P. DAHLSTROM, M. E. New York: E. & F. N. Spon, 1885.

This work was originally prepared and published by an engineering society of Stockholm, Sweden, it having been thought that the most certain way to insure economy of fuel among steam-users, as well as to prevent accident, would be to furnish detailed regulations and explanations to the men entrusted with the firing and management of steam boilers. The original work appears to have been favorably received, as it passed through a number of editions. The present volume is mainly a translation of the Swedish work, but has undergone some change and revision at the hands of Mr. Dahlstrom.

The book is quite brief—only 26 pages in all—but is very much to the point. It is divided into two parts, the first containing explicit directions for the general care of boilers and the second a short summary of rules for the guidance of the fireman. The first chapter carefully explains the proper manner of firing, by which the greatest efficiency is attained with the least expenditure of fuel, a matter which requires much experience, intelligence and judgment, contrary to the opinion of many owners of boilers, who think that the cheapest man they can hire is necessarily the most economical, forgetting that he may easily waste enough fuel and do enough injury to the boiler to amount to many times the sum total of his wages. Another chapter is devoted to the maintenance of a proper supply of water in the boiler, in connection with which, the management, of the feed-pumps, injectors, gauges and other appliances is set forth in detail. The process of emptying, cleaning and refilling the boiler is given, with great particularity.

The whole work is couched in the plainest possible language; is eminently practical, and within the comprehension of any workman of the most ordinary intelligence. We should be glad to see it in the hands of every fireman, engineer and boiler-owner in the country. It is scarcely possible that any such person could fail to find within it some piece of information of far more value than the trifling cost of the work. The book is clearly printed in a convenient and portable form on good paper, and is substantially bound.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents. Anonymous communications cannot be noticed.

The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.

In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.

Sketches and drawings for illustrations should be on separate pieces of paper.

All communications should be addressed EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

ELECTRIC LAMP HANGER.

[31]—Instead of the adverse opinion given in answer to inquiry of "T. D. R." referring to "raising and lowering of arc lamps," page 24, vol. 4, would not impartial justice rather have referred him to parties who, claiming an exact acquaintance with every form and feature of the device referred to, could speak advisedly?

But we beg to take back this suggestion if "T. D. R." was simply the victim of a typographical error.

T. & J. W. WARD.

Room 2, Montauk Block,
Chicago, Jan. 28.

CORRECTION IN PATENT STATISTICS FOR 1884.

[32]—Please insert the following correction.—In my statistics of electrical patents on page 45 of your February issue, a trifling error has been printed. The following is the correct reading:

Conductors:

Cables—Compound Conductors and manufacture of the same	41
Insulated Wires, etc.	17
Insulating Materials	8
Line-wire—Compound Wire, etc.	13
Underground Systems	51

The record may as well be correct.

THOS. D. LOCKWOOD.

Boston, February, 5, 1885.

QUESTIONS AND ANSWERS.

[58.] **Works on Atmospheric Electricity.**—G. E. C., Stoneham, Mass., asks:—What is the best book on Atmospheric Electricity? **Ans.**—We know of no special treatise on the subject of any great value. Noad's *Manual of Electricity*, a large and rather expensive work, contains, perhaps the best exposition of the subject. An excellent paper, by David Brooks, may doubtless be obtained of the author, 2,008 Chestnut street, Philadelphia. If you wish to pursue the subject it might be well for you to subscribe to the *American Meteorological Journal*, $3 per annum, W. H. Burr & Co., Detroit, Mich.

[59.] **Electrical Indicator—Dynamic Units.**—G. N. V., Linden, N. J., inquires:—1. Would a good system of transmitting the variable indications of thermometers, barometers, height of water, etc., automatically, over a single wire, keeping both transmitter and receiver in perfect unison, with an open circuit battery, be a paying invention? 2. In thermo-dynamics, what is an unit of heat, and an unit of work, and what relation do they bear to each other? **Ans.**—1. We cannot undertake to predict whether any given invention will "pay." As a rule the pecuniary results depend far more upon the business management, than upon the merit of the invention. Such a system is now being introduced in this country. See page 265, vol. iii., of this journal (December, 1884). 2. The unit of heat is usually defined as the quantity of heat required to raise the temperature of one gramme of pure water, at 0° centigrade or 32 Fahrenheit, through one degree centigrade. It is called the gramme-*degree*. The unit of work is called the *erg*. It is the amount of work done by one degree working through the distance of one centimetre, the degree being the force which, acting upon one gramme for one second, generates a velocity of one centimetre per second. One gramme-degree is equal to 42,000,000 ergs. By Joule's original determination, 772 foot-pounds of work is equivalent to the quantity of heat required to raise one lb. of water through 1° Fahrenheit.

NEW YORK AND VICINITY.

The Complicated Competition Among Quotation Companies.—The Gold and Stock Telegraph Co. Moves its Headquarters.—Tottering Telegraph Companies.—A Brilliant Resolution.—Long Distance Telephony.—Electric Lighting for the Post-office.

It is doubtful if there has ever been a period of such fierce competition in various branches of electrical service as at the present time. The business of lighting the streets appears to be amicably divided between the local United States, and Brush companies. In isolated plants, however, there is considerable rivalry both in arc and incandescent lighting. Those who engage service of this kind should make their bargain with care, as we learn of one instance where a patron desired to dispense with the old, and substitute the new, but the original occupant refuses to budge, and the other company will not run its wires, until the old ones are out of the way, while the owner does not dare risk the lives of his subordinates in the hazardous employment of removing dead wires.

The field so long and successfully cultivated by the Gold and Stock Telegraph Co., is being vigorously stirred up by its rival, the Commercial Telegram Co., whose managers have been stimulated to renewed exertions, by the decision in its favor, referred to in these columns last month. The Baltimore & Ohio company is also preparing to engage in a similar service, and if it follows up the quotation business with a war of rates, none of the contesting parties will enjoy the comfortable revenue earned for so many years past. The Stock Quotation Co., under the supervision of Mr. W. F. Coffee, is actively engaged in construction, and notwithstanding the state law, the wires are being placed overhead, but on housetops instead of poles. Superintendent George B. Scott, and Assistant Superintendent Charles S. H. Small have removed from the offices occupied by them in the Western Union building, to the new offices at No. 16 Broad street, which is in the heart of the stock brokers territory. The operating department of the company will soon follow, and battery power will be dispensed with, as arrangements are now being perfected to depend entirely upon dynamos to drive the hundreds of type-printing instruments. It is only about eight years since this extensive operating plant was moved from 61 Broadway to the then new Western Union building, which at the time was very generally considered an unwise change. The entire expense of the two removals, will probably exceed $200,000.

The competition of these different quotation companies is further complicated by the prospect of a war between the different exchanges, all of which depend more or less upon the telegraph companies for their quotations, The contract by which the Gold & Stock company held its privileges upon the floor of the Stock Exchange expired some time ago, and for the monopoly of such a right it agreed to enter vigorously upon a war of extermination against the bucket-shops. This matter has been discussed by the Governing Committee of the exchange but no decision ever reached. It is now reported that the company has made overtures to the Mining Exchange, the consummation of which would necessitate its entire withdrawal from the Stock Exchange. In this case the latter would probably depend on the Commercial Telegram Co., as it would scarcely be possible for it to organize a perfect system of its own in less than six months. As the Calahan patents upon which the Gold & Stock company has based its claims for many years expire very soon, it will readily be seen that there is every probability of quite a disturbance in the financial district of the metropolis.

The tribulations of the Bankers and Merchants' company under the receivership create considerable gossip. The six months default of the interest due on the bonds of the American Rapid company has about expired when the owners of the latter will make a move to regain possession of their property. Meanwhile there are rumors of various deals, both with the Western Union and Postal companies. A report has also been circulated that the latter company was to be wiped out of existence on account of its inability to meet its obligations. All reports of this character are vigorously denied by interested parties, yet dissolution or consolidation in some cases, can only be a question of a year at most.

The following is one of a series of resolutions, offered by Mr. O'Donnell at a meeting of the Railroad Commissioners at Albany on the 13th inst., which were adopted by that body.

Resolved, That a communication be sent to the elevated railways of New York city inquiring as to the utility and practicability of providing a system of lighting the entire length of the tracks of their respective roads with electric lights, to be used in case of foggy weather, with a request for an answer within 10 days.

It would be interesting to know what this gentleman desires to accomplish.

The long-distance telephone enthusiasts continue their periodical tests with Chicago over the wires of the Postal company. The immense satisfaction derived from the conversation is reported as follows in a New York daily, whose reporters are apparently never omitted when the invitation lists are made out. Mr. Eastman of New York and Mr. Armour of Chicago were the participants:—

"Is it true that Chicago girls have big feet?"

"You mustn't ask me such questions," called back Mr. Armour. "Ask me something easier."

Mr. Eastman put his lips to the instrument again and asked in a lower voice: "What is the price of May pork?"

"May who?" inquired Mr. Armour from Chicago.

"May wheat," yelled Mr. Eastman, changing his question.

"I don't know who you mean," replied Mr. Armour, apparently a little confused.

"What was the run of cattle to-day in Chicago?"

"Five thousand," came the answer.

"Correct," said Mr. Eastman. "Can't you tell me now what May wheat closed at?"

"Eighty-four five-eighths," came Mr. Armour's answer, and Mr. Eastman repeated it to the waiting guests in the Postal company's New York office.

Among the original locations of the arc lamps in this city were the Post-office and the Grand Central depot. Both of these buildings are now lighted with gas. The complaints of impure air, and defective illumination in the Post-office have however led to a further investigation of the merits of electricity, and United States Marshal Erhardt has for some time been in favor of substituting it for gas. It is now proposed, however, to make more general use of the incandescent lamp, which if properly introduced will probably remain.

New York, February 25, 1885.

CHICAGO.

An Important Call-box Patent.—A Novel Telephone Exchange Enterprise.—The Central Union Company's Lines.—A New Storage Battery.—Underground Progress.—The Dorsett Conduit System.—How a Gas Engine was Tamed.

All who are familiar with the mechanism of telephone call-boxes are aware of the many devices for shunting the circuit, invented by the various manufacturers. From the original, which required the manipulation of a push button, there have been constant changes to produce automatically the same result by the turning of the magneto crank. In one of these the crank is insensibly thrust inward to shunt the circuit, another produced the same change by centrifugal force, a third accomplished the same result by means of lost motion on the attachment to the crank shaft, and so on. Each of these, to a greater or less extent, has been adopted by telephone companies, and several of the various systems have been in interference in the patent office. The outcome of all this contest has been reached, and December 23d a patent was granted to Elisha Gray, two of whose claims are as follows:

The combination with a magneto or dynamo-electric machine, of a main

Digitized by Google

circuit and a shunt or short circuit around said machine, and means for automatically breaking such short circuit upon and continuously during the operation of said machine.

The combination of a driving shaft of magneto or dynamo-electric machine and a sleeve mounted thereon, in such manner as to have a longitudinal movement thereon, and a circuit breaker automatically operated by the longitudinal movement.

As a very polite captain of home guards used to say, during the late war, so may it be remarked to some venders and users on this solemn occasion: "About face, gentlemen, if you please."

A party who shall be nameless, lately conceived the idea of an independent telephone exchange here, and obtained a public telephone, which was placed in his office. It hardly seemed to the telephone people that he was justified in doing this, considering his business location and other circumstances. In the course of a few days, however, it was discovered that he was doing a rushing business with his public telephone, and investigation showed that he had opened an independent exchange, switchboard and all, and was giving city connections to parties using "bogus" instruments on about 15 surreptitiously placed lines leading to his office. His wires, and his revenue as well, were suddenly cut off one fine day, and the flourishing little exchange has been closed.

The Central Union company claims to have about 10,000 miles of toll line wires scattered throughout their territory. They have 140 complete exchanges, and a lot of "kitten" exchanges, with from two to ten subscribers each, about 100 in number. Between Lasalle and Peru, in this state, where they have several wires, there is a lot of zinc furnaces which the lines pass in the immediate neighborhood of. The fumes from these furnaces, which are largely sulphurous acid, are very destructive to wires, and a No. 8 wire will last only about three years. A letter was shown me a few days since, in which the party in charge there showed much nervousness in anticipation of bad weather. A piece of line wire which had been sent to the general office, showed that such fears were not without foundation, for this sample, which two years ago was either a No. 12 or 14, had been reduced to nearly a 20 when taken down.

Mr. Chas. Wirt, of the Edison company here, has lately made a small storage battery which has some peculiarities worth noticing. The cells are made of sectional candy jars, such as confectioners place in their show windows. These sections are each complete in themselves, and fit so that each makes a cover for the one beneath it. In the bottom of one of these he has placed a concentrically wound pair of plates of sheet lead, one of which is corrugated. The two strips, thus wound, give large surface, being an inch high and several feet long. The coil is about five inches diameter and rests in the bottom of the jar like a roll of tape. Upon this he placed four half-inch sections cut from an argand glass chimney. These serve for the upper plate to rest upon, and permanently separate the plates. Above this is the second lead coil, similar to the lower one. The whole is then thoroughly sealed in with shellac, save a half inch hole at the top, to allow hydrogen to escape. Two such cells are mounted, one above the other, and these are connected by insulated lead strips in series. It is easily inspected and clean, easily handled, and works very satisfactorily. Mr. Wirt says the internal resistance is greater than he anticipated, and that in future he will cut his glass supports of less height.

A recent letter from Prof. Barrett, Superintendent of city telegraphs, shows that a very general acquiescence in the demands of the city is noticeable, in the matter of underground wire placing. The W. U. Telegraph Co. have 75 miles already, and will eventually have about 500 miles buried. They have laid conduits from their office on Lasalle street to the new Board of Trade, and from Van Buren street south to the city limits, all of which, if the weather ever lets up, will be wired, and the line of poles down Clark street, belonging to that company and its adopted child the Mutual Union, cleaned out. The B. & O. having shaken off the old-man-of-the-sea injunction, which checked them, will proceed to fill their conduits at as early a day as practicable. The Bankers and Merchants are already buried—their wires, you'll understand—the Postal company has 180 miles underground, the Western Indiana has several miles, the City has about 60 miles and plenty more to go under early in the spring, the Telephone company has about 28 miles now under, and will bury more as fast and as far as is practicable, and the electric light companies will "go below" as their needs require. So that in a short time Chicago will probably lead in the matter of clearing up the pole and wire nuisance to a greater extent and more perfectly than any city in the world. His letter concludes: "Chicago was first to see the danger, as she was first to adopt a remedy for the cumbrous and daily increasing net-work of overhead wires, and has, I think, to-day, more miles of underground wire than any city in the Union."

The Dorsett system of underground electric conduits, which has been referred to in these columns, and which has been adopted by the city authorities for their wires, is the system that the Chicago Sectional Electric Underground Co. has also adopted, and is going to use in constructing a very elaborate and comprehensive "plant" as soon as the weather permits of the streets being opened. Mr. Dorsett's material is a composition of prepared asphalt, concrete, sand and other substances, the formula for which is patented and has been in use for several years for water and sewer pipes. It is as hard as rock and practically imperishable. It is made into cylindrical sections three feet long with a flange on one end, and of two sizes, one of 10 inches outside diameter containing seven 2¼ inch holes separated from each other by three-quarters of an inch of the material, and one of 16 inches outside diameter containing 19 2¼-inch holes separated as in the smaller size. These sections are bedded in sand, or other suitable material, in a trench, and the holes of one section are made perfectly true to those of another by inserting an expansion rod into two of the holes past the joint and leaving it in position until the two sections are united together. This is done by ramming some of the hot material into the space between the bell and spigot with a hot tamping iron, making a solid and homogeneous mass.

The manhole is made of the same material and resembles somewhat a large, short-necked, round bottle, the neck part being 26 inches in diameter, the body 44 inches in diameter and of any required depth up to five or six feet. These manholes are made in one piece and when set into position a portion of the side is cut out to let in the main conduit from two or more directions; and the joint is made with hot material, as between the sections, making the whole perfectly gas and water tight.

In the iron pipe systems with brick manholes, now in use here by some of the companies, the leakage of gas into the junction chambers has become a serious difficulty and has already caused several explosions. Escaping gas from the street mains cannot find a vent through the pavement and works along through the earth filling every space and cavity, often causing much damage, and Mr. Dorsett considers this gas-proof feature one of the principal advantages of his system.

The conduit, when complete, consists of a number of 2¼-inch holes through an excellent insulating material and strong enough to protect the wires from mechanical injury, while it possesses electrical advantages not found in any iron pipe or metallic system. The compound being a good insulator, the wires in the holes will be less subject to retardation troubles, as they will be further removed from the earth, and will be better insulated, for the same reason. The material is also non-corrosive and not subject to rust as in iron, and cables pulled into the ducts may be removed and replaced with great facility. The Underground company also proposes to lay six-inch pipes with a shelf through the centre for electric light wires and has already several hundred feet of both styles of conduit laid. Work was commenced late last fall and was suspended until spring on account of the cold weather.

People who use gas engines for various purposes of electrical import, often have fun from their fitty characteristics, especially when a telephone exchange is dependent upon these for actuating their generators. A misunderstanding of this nature on two or three occasions in Milwaukee, recently, occasioned considerable trouble. Without previous warning or apparent cause, the blessed thing would occasionally stop to rest. The gray-haired president was, as usual, equal to the task. Along the driving shaft of the engine he placed a flat, weak spring, with a sort of hammer head at the free end. Connected with an insulated ring on the axle-bearing is a circuit, embracing a battery and two vibrating bells, one in the manager's room and one in the operating room, and connected thence to the shaft and spring. While the machine runs, the centrifugal force tending to throw the spring off, breaks circuit; but once at rest the hammer head of the spring closes by settling on the ring in whatever position it may stop. "There!" said the inventor, when he had finished it, "if you will try to stop and shirk your duty, I'll have the satisfaction of making you give yourself away *every time*"—and it does.

CHICAGO, Feb. 14, 1885.

PHILADELPHIA.

A City of Underground Skeletons.—Councils Decline to Proceed Against Overhead Wires.—Proposed State Legislation Against Overhead Wires.—The Court Decides that a Telephone Company is a Telegraph Company.—Annual Meeting of the Franklin Institute.

ALTHOUGH councils have in the last seven years granted many companies permission to put down underground wires in this city, it would seem that generally the privilege was about all that the gentlemen who managed the various companies wanted, because in most of the cases, beyond paying the money for the ordinance, they have done nothing. The first ordinance passed by councils granting the permission bears date May 16, 1877. It allowed the Atlantic & Pacific Telegraph Co. to lay and maintain underground wires in the city of Philadelphia. This company shortly afterwards was absorbed by the Western Union, and never took advantage of its privilege. In November, 1878, the Brooks Underground Telegraph Co. was granted permission to lay a line of wires along Fifth street, between Chestnut and Cherry streets. These wires were never laid. The Municipal

Digitized by Google

Telegraph Co., in January, 1881, had an ordinance passed, but never laid either wires or conduits. The Underground Electric Conduit Co. was allowed, on February 7, 1883, to put wires under Juniper, Broad and Merrick streets and South Penn square, but never did so, although the time in which it was to do it was extended by councils. The Morse Underground Co. was, on February 10, 1883, given until August 21 of the same year to lay a system of underground wires. It never did so, although it put down on private property 500 feet of wire for exhibition purposes. A company whose title was much longer than the wires it laid—The Metropolitan Underground Telegraphic, Telephonic and Electric Light Co.—received permission April 3d, 1883, but never did any work. The Philadelphia, Reading & Pottsville Telegraph Co. was authorized to lay a wire between Nos. 204 and 227 South Fourth street on June 29, 1883, and did so. The Continental Underground Cable Co. was given one year from July 7, 1883, to put down conduits and wires, but did not do so before the limit expired. There is an ordinance before councils now extending the time for another year. The Philadelphia Sectional Electric Underground Co. was authorized on July 12, 1883, to lay wires and conduits, and has laid about five miles of wires. It is this company's conduits that have been amusing themselves and startling pedestrians by exploding every once in a while. The Baxter Overland Telephone and Telegraph Co. was authorized on October 10, 1884, to lay wires and conduits on various streets of the city, but has done nothing yet. On June 21, 1882, the Brush Electric Light Co. received permission to lay wires and conduits. A line was put down on Delaware avenue, between Vine and South streets, but it proved to be a failure. On the same date the United States, or Maxim Electric Light and Power Co. also received permission, but never did anything. On March 21, 1883, permission was granted to the Baltimore & Ohio Telegraph Co. As yet it has done nothing, but the officers of the company expect to get to work in the spring. The National Underground Co. was granted permission on March 16, 1881. A cable was laid on Market street, between Front and Juniper streets. It turned out to be a failure, and only part is now underground, the rest having been torn up by the traction company. A. C. Yates & Co. have laid about 500 feet on Chestnut, near Sixth. Permission was granted them on February 7, 1883. Henry C. Gibson and others who use the Brooks system were granted permission on April 3, 1883, and have laid about four miles of wire, running from the Broad street station to Front and Norris by way of Third and Walnut. All of these companies are required to enter $20,000 security to the city that they will not consolidate; that they will pay their taxes; keep the streets in repair; be responsible for damages, etc. Up to the present time the only companies that have complied with this provision are the Brush, Philadelphia Sectional, and Henry C. Gibson & Co.

In comparison with the above showing in the matter of underground wires, it is of interest to see what Chicago has done in the same line.

At present there are down and in successful operation in that city 718 miles of wire, of which the Bankers and Merchants' Telegraph Co. own 400 miles; the Postal Telegraph Co., 150; the Chicago Telephone Co., 28; Western Indiana Railroad Co., 50, and the City and Fire Alarm Telegraph, 60. In addition to this, the Western Union will shortly have 500 miles down, and the Baltimore & Ohio 250, making a grand total of 1,468 miles of underground wires.

The greater part of the session of common council on the 12th of the present month was devoted to the discussion of the ordinance which proposed to allow the overhead telegraph wires to remain until January 1, 1886, instead of causing them to be placed underground at once. Some of the members fought the ordinance bitterly, and held that the companies had made no effort to take down their wires. It was moved that the consideration of the ordinance be indefinitely postponed, for the reason that the Legislature was now engaged in the consideration of a bill which, if adopted, would cause all telegraph and telephone wires in the cities of the state to be placed underground by the 1st of December of the present year. The legislative bill would render this ordinance inoperative. The consideration of the ordinance was thereupon postponed.

The bill above referred to as being introduced in the House of Representatives at Harrisburg, is as follows:—

SEC. 1. Be it enacted, etc., that all telegraphic, telephonic and electric light wires and cables used in any incorporated city of this commonwealth, having a population of 10,000 or more, shall hereafter be placed under the surface of the streets, lanes and avenues of said city.

SEC. 2. Every corporation, association or person owning, controlling or operating telephonic, electric light or other wires and cables, including what is known as telegraph poles and other appurtenances thereto, shall, before the first day of December, 1885, have the same removed from the surface of all streets, lanes or avenues in every such city of this commonwealth.

SEC. 3. In case the owners of the property above enumerated still fail to comply with the provisions of this act, within the time herein specified and limited, the local governments of the said cities of this commonwealth shall then, and they are hereby directed to remove, without delay, all telegraphic, telephonic, electric light and such other wires, cables and poles, wherever found above ground, within the corporate limits of their respective cities.

SEC. 4. No city in this commonwealth shall grant any exclusive privilege or franchise under this act to any corporation or individual, by which a monopoly may be created or competition prevented on equal terms.

SEC. 5. That any individual, firm, association or corporation, or any officer, agent or employe thereof, violating or failing to comply with the provisions of this act, shall be deemed guilty of a misdemeanor, and, on conviction, shall be punished for each and every offence by a fine of $1,000, one-half to be paid to the prosecutor and the other half to be paid to the county in which the conviction is had, and an imprisonment not exceeding two years, or either or both, at the discretion of the court.

SEC. 6. That all laws or parts of laws inconsistent herewith be and the same are hereby repealed.

Our state representatives and city councilmen seem to do a great deal of talking in reference to placing the wires underground, but I am inclined to think that the telegraph companies will be apt to nominate their own time in regard to the matter.

There are a half-dozen other companies after various privileges (chiefly underground) from the city, and as they are all likely to get what they want, it is to be hoped that they will be satisfied. But for the life of me I cannot see where they are going to derive any benefit from their privileges after they get them.

In the appeal of the Pennsylvania Telephone Co. from the settlement of the auditor-general and state treasurer, Judge Simonton this morning filed an opinion giving judgment for the commonwealth for $345.04, the amount claimed.

The tax was based on the report of the company showing its gross receipts for the six months ending June 30, 1883, to be $35,794.91, and under the provisions of the act of June 7, 1879, which imposes a tax upon the gross receipts of "every telegraph company" incorporated under the laws of this or any other state, and doing business in this commonwealth. The question to be decided by the court was whether the appellant was a telegraph company within the meaning of this act. The court reviews the subject at length, and in conclusion holds: "Both on the construction of the act under which the appellant is incorporated in connection with the taxing act and on general principles that appellant is a telegraph company, and as such taxable on its gross receipts."

At the annual meeting of the Franklin Institute, Col. Charles H. Banes formally presented to the institute the library of electrical science which was collected by the managers of the exhibition, to be kept as a memorial of that event. It is to be known as the Memorial Library of the Franklin Institute. The volumes, bound and unbound, number nearly 3,500, and embrace works of early and recent dates.

A resolution was adopted instructing the officers of the institute to take steps to obtain from Congress reimbursements for the outlay made by the institute in displaying the government exhibits.

Officers were elected as follows: president, William P. Tatham; vice-president, Joseph E. Mitchell; secretary, William H. Wahl, M.D.; treasurer, Samuel Sartain; managers, William Sellers, Hector Orr, Cyrus Chambers, Jr., Henry R. Heyl, Charles J. Shain, Charles E. Ronaldson, G. Morgan Eldridge and Hugo Bilgram; auditor, William B. Cooper; representative to the Pennsylvania Museum and School of Industrial Art, William H. Wahl, M.D.

BOSTON.

The Work and Improvements of the Fire Alarm System.—Time Distribution.—Electrical Lectures before the Society of Arts.—Close of the Electrical Exhibition.—Electric Train Lighting on the New York and New England.—Combination of the Edison and Thomson-Houston Interests.—A Conflict of Opinion about Lighting at Newport.—Proposed Time Ball on the State House.—Reception to Mr. Daft at Providence.—The Hartford Electric Light Co.—Fluctuating Telephone Shares.

THE annual report of the fire department contains interesting statistics of the work and condition of the fire alarm telegraph. Circuits have been rebuilt and repaired and new armored cable laid. The telephone service has been greatly extended, so that now there are 57 telephones in use—all of the houses of the department being connected with headquarters. Fifteen new signal boxes have been put up, making 330 boxes now in use. The keyless door, which saves so much valuable time in giving alarms, has been applied to 26 fire alarm boxes, in addition to six in use before, 23 more of the doors are ready, and will be put on at an early day, orders having been issued to supply all the boxes in the city proper with them.

New apparatus has been provided, consisting of an 18-pen register, a bank of 18 relays and keys, and an annunciator for the same. The Serson & Kauffer battery has been purchased to supply all the circuits, in place of the gravity battery. In the opinion of the fire alarm authorities the Serson requires less attention and lasts longer, a saving of time and material. The department has strung 70 miles No. 9 iron wire, 4,000 feet kerite wire, used 3,000 insulators, and 650 feet 7-wire armored cable. The number of alarms during the past year was 793, larger than for any year previous. The fire losses have been $998,554, and the insurance $7,981,807. Notwithstanding the large number of alarms, no fires of magnitude have occurred. The fire department pays the Cambridge observatory $400 per annum for the meridian time, or as we now have, standard time, which is struck from all of the fire alarm bells. The observatory derives

Digitized by Google

quite a revenue from this source, as all prominent watch dealers have a relay in their shops to give Cambridge time. The fire department has changed the bell and gong fire alarm signals as follows: First alarm, box number repeated twice; second alarm, 10 blows followed by the box number: third alarm, 10 blows twice, followed by the box number: general alarm, 12 blows twice, followed by box number. The changes consist in striking off 10 blows from the third and 12 blows from the general alarm, and providing that the box number shall follow the third and general alarms, as well as the second alarm.

Mr. George W. Blodgett, electrician, of the firm of Blodgett Brothers, manufacturing electricians, recently delivered two interesting lectures before the Society of Arts, at their new building, on the subject of recent improvements in "Electric and Interlocking Railway signals." Mr. Blodgett gave a *resumé* of the subject, taking up in course the various inventions, and closing with the remark that the subject was more complicated than would appear at first sight, and that many systems which worked well in small models or areas had made failures in actual practice. In his second lecture he detailed the leading systems in use, the Hall, the Union, etc.

Mr. W. J. Jenks of Brockton has also delivered a lecture before the Society of Arts, his subject being the "Edison Central Station Electric Lighting System." He explained the main principles of the Edison system and had an appreciative audience of experts and practical electricians. His particular object was to present the commercial aspect of the light produced by the Edison system. The lectures given by the Society of Arts this winter, on electrical subjects, have been of much interest, being usually by practical men.

The Electrical Exhibition closed January 24th after being boosted, petted and encouraged on all hands during the time of its existence. It was a feeble thing from its inception and should have been kindly stifled by its projector while a fetus.

The Trouvé battery and Woodhouse and Rawson incandescent lamps have been placed on the New York and New England Railway limited train, in the dining car. This is the same installation I noticed a few months ago as being applied to the Boston & Providence train. The company owning the Trouvé novelties in this country make these exhibits to show the public what they can do. I understand they are putting small installations into private residences; the battery is so portable and easy of renewal that it may well succeed in cases where gas cannot be obtained, or where a beautiful and elegant illumination is desired. The company do not say it is cheaper than gas at ordinary prices, or than oil lamps, but that it is better and safer.

The American Electric and Illuminating Co., have combined with the Edison people and are to use the Edison incandescent system for isolated lighting in connection with all of their arc lighting stations in New England, as well as with its isolated plants in the same territory. The Edison company with which the arrangement has been made, has the exclusive right for New England of putting in isolated installations of the Edison system. There is still another branch of the Edison parent company in Massachusetts, which also covers New England, for the purpose of organizing companies to light cities by the underground system. This branch has arranged with the American company to work in unison. This practically closes out any combination of electric light companies in this city.

Newport, R. I., has been exercised about the electric light question. There is a fight between the gas and electric light interests, the common council voted against the use of electric lights, and the committee on gas and lamps met to carry out the vote, but were confronted with a formidable list of petitioners praying for the retention of the lights. The aggravation of the thing is that two years ago by a popular vote the tax-payers decided by a large majority in favor of electric lights. The action of the council was secret and apparently in favor of the gas interest.

An order has been introduced in the state legislature to have a noon time ball dropped; the roof of the state house is the proposed location, a fine and sightly position, as the "gilded dome" can be seen from all points of the compass.

Leo Daft was given a reception in Providence, R. I., January 27th, by Mr. Wm. A. Harris and other prominent citizens of the state, who are interested in a company recently organized for the practical application of the Daft system for the electrical transmission of power. After the elegant lunch had been disposed of, Mr. Harris introduced Mr. Daft to the assembled company in a few well chosen and eulogistic remarks, whereupon Mr. Daft proceeded to give a review of the history of the development of electro-motive force from the days of Jacobi to the present time—including a detailed description of his own system. Gentlemen present who were familiar with the application of the Daft system gave the results of their experience in an interesting way. Subsequently the company took carriages and visited the Harris-Corliss engine works, where a central station has been established for the generation of electric power and its distribution by the Daft system, and they were then taken to offices a mile distant, where they were shown machinery in actual use, driven by power furnished through wires from that point.

The signal lights displayed at night from the flagstaff on the Post-office building by the United States signal-office consist of a lantern of thick glass, which is to have inside an electric light instead of the usual oil and wick.

The annual meeting of the Hartford Electric Light Co., was held on the 11th inst., the officers for the ensuing year being elected. The old board declared a quarterly dividend of 1½%. The company is earning 10% net above all expenses. It commenced business with 100 lights, since then it has increased them to 225, and will soon increase to 300. A complete central station of the Edison system will be added to the present arc plant.

The American Bell Telephone stock has suffered another sharp decline, running down to 208, and rallying to 217, where it has stood for some days. It looks now as though the shorts would have to cover, which will send the stock up again. The New England and Erie stocks act sympathetically with the Bell No one knows *why* the stock should decline and advance so easily any more than one can give the reasons for the actions of a coquettish young woman.

BOSTON, February 14, 1885.

WASHINGTON.

No Government Telegraph Action During the Present Congress.—Mr. Money May Carry His Scheme into the New Cabinet.—Charges of Inefficient Fire Alarm Management.—The Pan Electric Telephone.—The Baltimore & Ohio Company.—Another Underground Company formed.

THE closing days of the forty-eighth congress are at hand and as predicted in this correspondence, no action has been had in the matter of the control of the telegraphs by the government. At its opening there was quite a class in Congress, and out, who regarded "government control" as a sovereign remedy for all faults and abuses, whether by those who managed the telegraphs, the railroads, the banks or anything else. Reflection seems to have diminished this class here and elsewhere, and they are now apparently more willing "to bear the ills we have than fly to those we know not of." Mr. Money the chairman of the house committee on post-offices and post roads still firmly stands by his bill, previously noticed, and has only been prevented from pressing it by want of opportunity. He is now spoken of as a possible future post-master general under President Cleveland. Should he be selected, he would carry his ideas as to the telegraph with him, and possibly be able to impress them upon his associates in the cabinet. He is a man of much energy and force of character, and would be persistent in carrying out views that he believed after careful study were well founded. He is a man who would prefer to mark his administration of the office by an advance step in the march of progress rather than hunt the musty files for some evidence of delinquency on the part of his predecessors.

There is something of a stir among the local magnates over a recent charge made by the chief engineer of the fire department that the Fire Alarm telegraph, or its management, is inefficient. There has been a good deal of correspondence on the subject between the commissioners, Chief Cronin, and Supt. Miles, and a number of newspaper contributions on the subject. The trouble is alleged to have been crosses with telegraph, telephone and electric light wires. The remedy suggested by the parties to the controversy is the immediate substitution of cables for the overhead wires. This is also in line with the ideas of the commissioners who cannot well insist that the corporations bury all their wires while those of the district government swing overhead. The combination of circumstances makes it almost a matter of necessity for the authorities to set the example and test the experiment fully of a system of local underground wires. As the people are allowed no voice in the expenditure of their money there will be nobody to grumble if the experiment proves a failure.

The Pan electric people have put a pair of telephones on a single wire cable, running from the office of the sergeant-at-arms' in the senate wing of the Capitol to General Butler's house, just south of the Capitol grounds. The instruments are working well. I understand the Bell company are about to sue out an injunction for the infringement of the Bell patent as soon as the necessary papers can be made out. The Pan Electric Co. is a formidable one in names at least, having Genl. Joseph E. Johnston for president, Senator A. H. Garland (prominently named for the next attorney-general) as attorney, Senator Isham G. Harris, Hon. Casey Young, Col. R. F. Looney of Memphis, Tenn. and others, for directors. The nominal stock of the parent company is $5,000,000 and there are several local corporations with a nominal capital of from one to $4,000,000. Of the market value of these stocks I am not advised.

The experiment by the Edison company of lighting a portion of the senate chamber and lobbies has been eminently successful, and it is expected that the necessary money will be at once appropriated to substitute electric for gas light for that wing of the Capitol. The House end will await the result of the innovation.

The new building of the Baltimore & Ohio Railroad Co. to be occupied for railroad and telegraph purposes, work on which was delayed first by negotiations for the consolidation scheme and then by the weather, has been closed in and is being completed as rap-

Digitized by Google

idly as circumstances will permit. It will be ready for occupancy early in the next month. The company has been forced to connect its wires by means of underground cables. The distance the cables shall be run has not yet been determined by the commissioners.

There has been a company incorporated here under the general incorporation laws of the district: The Capital City Underground Telegraph Wire Pipe Co., with a capital stock of $50,000 which proposes to manufacture and lay pipes in which to place telegraph and other wires. Among the corporators are A. Worth Spates and Thomas R. Rich of Baltimore, who are also interested in the Monumental Wire Pipe Co. of that city. The Washington gentlemen have not heretofore been identified with electrical interests.

WASHINGTON, D. C., Feby. 16, 1885.

NEW ORLEANS.

The Great Exposition Now in Full Blast.—How the Different Companies Share the Illumination.—A Dearth of Electrical Exhibits.—The Wire Manufacturers Well Represented.—Popularity of the Electric Railway.

THE Exposition is now on a boom. With the exception of a few machines, the electric plants are all complete and running; the buildings and grounds are open till 10 p.m., and the visiting throngs witness such a flood of electric light as has never been seen before. Over 7,000 electric lamps (arc and incandescent) continue the illuminating contract when the sun goes down. The Louisiana Electric Co. has been very busy, and but two or three of its 35 dynamos remain to be put up. Its initial efforts here displayed in lighting this vast building must inspire the stockholders with hope for the future, and perhaps, as a result, the remaining installments due on stock will be paid promptly and with pleasure.

The South-western Brush company is now running under full head of steam. Five 65-light machines furnish 300 lamps to the government building and a few to the grounds.

The Jenney company has its groups of 10 lamps hung in mid-air, as they appear to be, and are certainly attracting considerable public attention By a slip of the pen, I stated in my last letter that this company has *five* towers upon the grounds, when in reality there are *six*. The plant consists of three each 30 and 15-light machines now running, and two more 30-light to be put in. They furnish 66 lamps to the stock barns, 29 to the wagon building, eight to some of the walks in the grounds, and 15 to the Grand Rapids Furniture Pavilion. This last named building was to have been lighted by the Edison company, but for some reason this change has been made. In addition to the above, one Jenney lamp will be placed on the steamboat landing and two in the water-works building.

The Thomson-Houston company has two 30-light machines in Main Building, running in connection with four like dynamos placed in Machinery Annex, from which are wired 75 lamps in Horticultural Hall, 23 in Saw Mill Building and 25 in the Annex itself. Besides, they drive four Cleveland motors used by H. Muhr Sons, of Philadelphia, who manufacture souvenir gold rings. They are the only electric motors (the Daft Railway excepted) so far observed *in use* in the Exposition. An Edgerton motor on exhibition running a sewing machine is also run by this company.

The Philadelphia Exhibition, lately held, having shown what electric light companies can do in the way of attractive displays, we must say the exhibits (?) in this line here are, to draw it mildly, *tame*. The Edison company has excellently situated space, from the centre of which rises a group of colored lamps, producing a pleasing effect. Beneath, and under the shadow of its support, hangs a drop light, bringing out in perfect relief the various colors in a piece of patch-work placed below. A case of lamps ranging from one to 100 candle power, a sample of each of the 15 sizes of wires used in lighting the Art Gallery, a picture of the "Pilgrim," bearing the legend that she is the largest steamboat in the world, and carries the largest electric light plant afloat (960 lamps), a few sections of underground conduits, a motor and fan, and an armature—this about constitutes the Edison company's display.

The Jenney company, near by, displays a large case of Wallace diamond carbons, of great variety of sizes, and a miniature star tower, upon the top of which are to be placed three Edison incandescent lamps.

The Thomson-Houston Co. exhibit a number of arc lamps of different mechanical arrangements. A tastily arranged little office shows the Thomson incandescent lamp to advantage.

Electric exhibits in general are few and far between. Can they all have gone to Boston? Among other things, the Roebling company display hard-drawn copper and also galvanized wire for electrical uses.

The American Electrical Works of Providence show a great variety of insulated and lead-covered wires, telephone cords and aerial cables.

Bare wires, both copper and galvanized iron, enter into the very complete exhibit of the Washburn & Moen company. A thermostat, as simple as it is novel, and an electric bell, with constant ringing attachment, together form a local fire-alarm system, and is the electrical contribution of this city to the Exposition.

Electrically speaking, the golden glory of Music Hall, as seen from its main entrance, and the silvery beauty of Horticultural Hall, viewed from a distance, divide the honors (at night) of the Exposition, although the electric railway claims no small share of public attention. This connects the government and main buildings, the track being some 1,100 feet long, the equipment consisting of a Daft dynamo in Main Building, a motor and three cars. The "electric glide," as a trip over this, the first railway of its kind in the South, is called, is now one of the features of the Exposition.

The financial troubles under which the Exposition has been laboring have been felt by the electric light companies, as none of them have been paid anything up to date on their contracts. A draft of $5,000 of the Louisiana company accepted by the Exposition, fell due a few days since, but no funds being in hand with which to meet it 15 days' extension was asked and granted. Aside from this, the only other company heard from, has been the Edison, which has endeavored to procure payment by suggesting that no cash being forth-*coming*, their plant would be forth-*going*, but neither has occurred as yet. However the many clouds which have been hanging over this great undertaking seem about clearing away. With the increasing attendance and perhaps another appropriation from Congress all existing debts will be paid, a good financial status obtained and happiness reign alike among the creditors and board of management.

NEW ORLEANS, February 19, 1885.

COLUMBUS.

Defeat of the Resolution Supporting the Sumner Postal Telegraph Bill.—Alleged Fraud in Its Passage Through the House.—Final Disappearance of Its Friends.—The Regulation Underground Bill Sticks Its Head Up.

THE Ohio Legislature has just disposed of a resolution recommending the adoption of the Sumner Postal Telegraph Bill now before Congress, and instructing the Ohio senators to work for its passage. In the House where the resolution originated it was defeated but afterwards reconsidered, and upon the final ballot declared adopted by just the requisite number of votes. It soon transpired however that five names appeared upon the roll-call as voting *aye* when in fact four of the members were absent and one declined to vote. A resolution was at once adopted providing for an investigation with a view of ascertaining how the fraud was consummated. A committee has not yet been appointed to conduct the investigation and will probably not be—the House does not seem anxious to investigate itself. Yesterday the resolution was reported back in the Senate without any recommendation from the committee having it under consideration—the vote stood 27 to 0 against adoption. Not a friend of the postal scheme could be found in the Senate. Five speeches were made, strongly condemning the proposition for the government to engage in the telegraph business. The usual underground bill has made its appearance this session but does not seem to have many advocates.

COLUMBUS, O., February 19, 1885.

SAN FRANCISCO.

A Field for the Electric Railway.—Mr. Gamble's Mission Involved in Mystery.—The Western Union Delivery.—Legislative Raids on the Telegraph Tariffs.—A Rich Telephone Territory.—Mormon Interest in Electrical Affairs.—Overworked Telegraphers.—The Regulation Rumor of an Organization.

HAVE any of your eastern *savants* as yet practically operated an electric railway? If so, and such a man can give bonds he, can, I think, secure a good contract from one or more lines in San Francisco. The cable lines leading from the Ferry to the Park and the Mission are simply coining money. Parallel with this line, running mission-wards, are the Mission street, the Howard street, and the Folsom street horse railways, yet on account of better appointments and steadier gait the public prefer the cable. Some years ago Woodward, of Woodward's Gardens, and the owner of the Mission street line, experimented on an electric road but it proved a failure, why? Are our electricians behind those of Germany or even old Ireland? Gentlemen, here is a chance for you. Make your propositions to Mr. Woodward of the Mission line, Peter Donohue of the Howard street line, or Michael Skelly of the North Beach and Mission line. The entire route of the three is on a level, from the Ferry to 26th street or further. Prove, for the present, you can run as fast (8 miles an hour) and work it as cheaply as the Market street cable and you will find ready "takers."

Digitized by Google

Mr. Gamble denies in a quiet way that he is here in the interest of the Postal company, but does it in such a mild manner that one would think, he but half meant it. One thing is certain, *he is here for something.*

I did Mr. John Barry an injustice when I said, most of the Western Union delivery was done by the American District System. I should have said the outside business, as only $\frac{1}{8}$ of the entire business is delivered by the District messengers. Jack being a veteran and a capable man, I make the *amende honorable.*

The Legislature now being in session, ambitious statesmen eager for renown and a grateful country's applause, are inventing all kinds of telegraph rate bills, one regulating a tariff by every 50 miles, another by a minimum and maximum rate, and another by a bill making it an incorporate part of the civil code, that in the event of a reduction being made to meet rivalry, that it shall not be in the power of the corporation to again raise said rate to its former standard without invoking the aid of the Legislature. Of course the superintendents of telegraph and telephone companies will be heard before the Committee on Corporations reports on them, and it is probable these bills will meet the fate of many a great scheme—die young.

Perhaps there are few districts in which the Bell telephone pays better than in that of Utah, Montana and Idaho, owned and operated by G. S. Erb, C. F. Annette and a few more gentlemen of Utah. J. J. Dickey, Sup't and A. J. Pattison, Manager of the Western Union, first started the telephone and district systems, and recently sold out to the above gentlemen at very high figures, when it was stated that the Western Union company compelled them to do so or else sever their connection with that corporation. Mr. Pattison is now managing the Drawbaugh system in Toronto, Canada, of which country he is a native. The Mormons are great patrons of the telephone and electric light and as many of the "Twelve Apostles" are shareholders there is no fear for lack of capital. The corporation covering this territory is the Rocky Mountain Bell Telephone Co., and on January 1st, 1885, it had 22 exchanges, with 1,460 subscribers, being an increase of seven exchanges and 452 subscribers during the year 1884. It also operates about 500 miles of extra-territorial and toll lines.

About 60 arc lamps are used at Ogden, and double that number in Salt Lake city.

The manner in which operators are worked at Ogden, Utah, if their stories be true is a shame. Men who come on at 6 p. m. and work continuously on heavy overland business until 5, 6 and 7, the next morning are again made to report at noon for lunch relief, and without a cent extra pay over the regular day's salary. In a measure, the night men here are similarly treated save reporting at noon, but these orders are not the fault of our managers, they come from Chicago. I have heard a rumor of an organization being started throughout the United States, through which operators would arrange through lawyers for suing the telegraph companies for damages caused by errors, when such errors were made by incompetent or overworked men. The operators here say the men in New York are allowed "extra," or a force sufficient to avoid the necessity of overwork is employed. Why is it not so all over? By hard work all around our men here are able to get off in time when the wires are working well, but when storms arise, as is frequently the case in winter, then the night men suffer. It is not for me to criticise, but I think a man who works 8 hours on an Overland circuit should be paid extra for every moment he works beyond that time.

SAN FRANCISCO, February 10, 1885.

ELECTRICAL NEWS AND NOTES.

TELEGRAPHIC OCCUPATION OF RAILROAD LOCATIONS.

SPECIAL REPORT OF THE MASSACHUSETTS BOARD OF RAILROAD COMMISSIONERS.

[CHAP. 59.]

RESOLVE relative to the occupation of Railroad Locations by Companies organized for the purpose of Transmitting Intelligence by Electricity.

Resolved, That the Board of Railroad Commissioners is hereby instructed to investigate the subject of the occupation of railroad locations by more than one company organized for the purpose of transmitting intelligence by electricity, including the necessity for and propriety of such occupation, the terms and conditions under which the same may be properly and safely permitted, the character and nature of the structures to be used, the regulation of their construction, repair, maintenance and operation, and to report to the next General Court the result of their investigations, with such recommendations and suggestions as they may desire to make. [*Approved May* 27, 1884.]

AFTER full notice a hearing was had under this resolve, and the question was argued, and testimony was introduced by able counsel representing the Baltimore & Ohio Telegraph Company in favor of legislation, and various railroad companies in opposition. No one appeared for the public or suggested any public demand for new legislation, nor did any one attend the hearing except the representatives of the above named corporations. The Commissioners regret the necessary length of this report; but when an important subject is referred to them by the General Court, it is a plain duty to investigate it thoroughly, and to report fully.

There is no serious question as to the power of the General Court to act upon this subject. Legislative authority over the railroad charters of Massachusetts is almost unlimited. Nothing is suggested as to any of these charters which forbids the legislation proposed. Nor can it be doubted that a franchise may be taken for the public good, in whole or part, as well as any other property; and land devoted by law to one use, has been, and may be, subjected to another use upon payment of damages.

An ingenious argument has been made to show that the proposed act would be void as conflicting with the United States Constitution and with Congressional action under it. It is said that the power of Congress to regulate internal commerce, includes the instruments of commerce, such as vessels, carriages and telegraphic lines. When Congress has acted, any state is ousted of jurisdiction, and *cannot even legislate in furtherance of the Congressional system.* But Congress has acted, first, by declaring railroads to be post-roads; secondly, by allowing telegraphic lines to be constructed on post-roads, and also by granting certain privileges to telegraphic lines.

Therefore the state cannot even aid Congressional action by giving power to locate telegraphic lines adversely. Congress has one scheme. The proposed legislation sets up a different scheme. And even an act not applied in words to inter-state telegraphy would be void as attempting to place under state jurisdiction telegraphic locations which are within United States jurisdiction, and which are connected with other lines extending through more than one state. And the case of Pensacola Telegraph Company *v.* Western Union Telegraph Company, 96 U. S., is cited. That decision, however, by no means covers the point in question. It was obtained by the Western Union Telegraph Company, then appearing as a progressive enemy of monopoly, and seeking to break up the exclusive right of an established company.

The court held that an act of Florida, giving exclusive rights to one telegraph company to construct and maintain lines in certain counties, was unconstitutional and void, as conflicting with the legislation of Congress on this subject. A decision that a state cannot exclude telegraph companies from its territory does not necessarily imply that it cannot admit them.

Nor has any case gone to that length, while many decisions take it for granted that states may lawfully allow the construction and, to a certain extent, regulate the operation of railroads and telegraphs, although Congress has legislated as to their location. It was said at the hearing that the acts of many states as to telegraphs were unconstitutional in this view. It may be added that the legislation of every state as to railroads would be set aside if this doctrine were sound.

The claim is that a state cannot by general law authorize the taking of a route for the construction of telegraphs, because Congress has by legislating on the subject deprived the states of jurisdiction. Applying this to railroads, Congress has undertaken their regulation (1) by the act of 1866 already cited, making railroads post-roads; (2) by an act of July 15, 1866, authorizing connections, and the formation of continuous lines; (3) by act of October 1, 1872, as to the transportation of live animals; (4) by acts regulating the span of bridges over navigable rivers. Therefore, the state cannot authorize the construction of a railroad by general, or special charter, especially if it connects with a road in another state, or with any road so connecting. Nor is it easy to see how it can legislate as to the operation of railroads even by requiring safety devices, if Congress by acting has acquired sole jurisdiction, and disqualified the state even from "supplementary legislation."

The answer to this whether as to telegraphic or railroad matters, is that Congress acquires exclusive authority, as to matters affecting inter-state commerce, only when it shows an intent to do so, and to regulate the whole matter; and that it has shown no such intent, either as to railroads or telegraph lines. On the contrary, the very act under consideration (sec. 5,263, Gen. Stats.) assumes that the state can establish telegraph companies. Its first words are: "Any telegraphic company *now organized, or which may hereafter be organized, under the laws of any state,* shall have," etc. One condition of the privileges conferred is, that the state shall have assumed jurisdiction to create a telegraphic company. And no intent is shown to prefer special legislation, or to confine the favors granted by Congress to companies that have acquired their rights with consent of the owners of the land taken for routes. The remark by the chief justice, in the case cited above, that the act of Congress only applies "whenever the consent of the owner is obtained," is a mere slip of the pen. Nothing of the kind is found in the act. To deprive the state of legislative power, there must be (1) an exclusive grant of power to Congress in the United States Constitution, or (2) an express prohibition of state legislation, or (3) an inherent incompatibility in the existence of joint jurisdiction, or (4) an intent to exclude state regulation. Neither of these exists here. And least of all is there an intent to deprive the state of jurisdiction in an act which grants a favor to

Digitized by Google

a company upon express condition that it has secured state action.[1]

The power to pass the proposed act may safely be assumed. But the power to pass an act does not necessarily prove its wisdom or require its passage. All things which are lawful under the constitution are not expedient. Authority to create a new danger for all travelers does not necessarily imply a duty to exercise that authority. The question of expediency is not a question between the Western Union and the Baltimore & Ohio or any other company, nor between any telegraph company and the various railroads. It is solely a question of public convenience, including of course the highest kind of convenience—the public safety. It is true that the Board has heard objections to the proposed legislation from various railroad companies, and that their opposition may be grounded partly on the fear of actions for damages resulting from adverse occupation of their tracks. But the interest of the public to prevent accidents is infinitely greater than that of the companies to avoid suits. And the danger is not that of the companies, but of the traveling public.

The general right of imposing a new use upon land devoted to a corporation for a public purpose is precisely the same with the right to take any other land, neither greater nor less. It depends upon public exigency, and upon a balance of the gain and loss to the public in so doing. The idea that because land has once been taken for a public purpose, it may therefore be more readily taken for another, or that it may be so taken without a clear exigency, is akin to the common notion that the locations of railroads are public property, which leads so many to violate the law, and to risk their lives by walking upon the tracks. Four-fifths of the land in locations is owned in fee by the railroad companies. But as to the other fifth, their ownership, while they operate the roads, is as exclusive as that of any land owners. The right of taking, in whole or in part for a new public use, land already devoted to public use, for a railroad is, as has been said, the same in principle with that of taking a portion or the whole of any man's homestead, but with this difference, in the practical application of the principle. Taking the homestead only injures the owner, and his injury will be fully paid Taking railroad locations may endanger the public, and for this injury there is no redress. Instead of saying, "This land has once been taken for a railroad, therefore we can take it for a telegraph company," it would be more correct to say, "This land has been set apart for public use as a railroad: therefore you shall not take it for any other use, unless you can show that it will not endanger the public." This view is probably the reason why in England, where the public safety is more carefully guarded than here, no telegraphic works are permitted to be placed on railways without the consent of their managers, except that the postmaster-general may use locations for such works, when railway companies are unable or unwilling to do so.

There is no doubt that it is desirable to have in every great centre of business independent telegraphic lines, not only as a means of insuring better accommodation for the public, and cheaper rates, but as a protection against the danger of having news suppressed, or false news transmitted, to the profit of telegraphic managers, and to the injury of the public. Such a result is probable, where exclusive control of telegraphic news is given to one corporation; and when through the virtue of managers or from any other cause the evil does not arise, it is still suspected by the community. Possibly this evil can be finally cured only by governmental telegraphy. But the need of rivalry does not necessarily prove the necessity for occupying railroad locations.

It is supposed that cheaper facilities may be supplied by the cheaper construction and operation of telegraphs upon these locations. Assuming that a hundred dollars per mile, or a little more, may be saved in the work of construction, it should be remembered on the other hand: 1. That the land damages would be far greater than those resulting from construction outside of the location or on the borders of highways. The right of way in such cases can be procured at very low rates. The right of way from Eastham to Taunton, 70 miles, was obtained for less than 10 dollars. This is not likely to be repeated; but it is clear that land within a railroad location will be far more costly than the average out of a location. It has already been purchased or condemned at a high, perhaps an exorbitant, rate. The annoyance and risk would be considered; and no railroad company would be willing to have its location so occupied without payment of far more than $100 per mile.

2. The idea of cheap construction is founded partly on the belief that the occupation of a track would carry with it the right to deposit materials between stations. And this is a separate element of danger. The views of the Board upon this point were set forth in a report of May 17, 1884 (Baltimore & Ohio Telegraph Company *v.* New York & New England Railroad Company): "It is no doubt true that in the infancy of railroads, when little business was done, certain kinds of freight, especially cordwood and manure, were received and delivered at other points than stations, and that as a favor in special cases, building materials were sometimes so delivered. But it is also true that as railroads increased their traffic, and as their managers increased in knowledge, this practice ceased to exist. And it is hardly necessary to say that on crowded roads the delivery of freight at points which are not stations, and which are without side tracks, is not only a hindrance to business, but a great cause of danger. An occasional favor of the kind referred to would not be a foundation for a request that the practice be extended, but it might well lead to a recommendation by the Board that it should be stopped. While the scattered instances of freight delivery between stations do not make a precedent for demanding such delivery as of right, it is plain that a recommendation made under the statute, founded on exceptional cases, would constitute a precedent. And this, if followed up, would seriously obstruct and endanger travel on our railroads." This right of delivery between stations has not been granted by general laws upon the subject, and it is not given by the laws of Ohio and Louisiana to which we were referred by counsel as models.

3. It is a question as to whether inspection of telegraph lines can best be done on a railroad or on a highway, and upon this and other points we have the report of an expert whose standing and experience give great weight to his opinions. This is appended in Note A.

4. In considering the proposed advantage of constructing and operating telegraphic lines on a railroad track, we should remember that the public, while it must lose something in safety, may gain nothing in convenience or in cheapness, unless it is secured by legislation. No such legislation has been suggested by the advocates of a new law. The general question of cheapening by competition will be considered hereafter. The proposed legislation on its face only aims to relieve new corporations from pecuniary expense at the cost of increased danger to the whole traveling public. Even this object would not, as we believe, be accomplished.

The chief objection to allowing the adverse possession of railroad tracks by an indefinite number of telegraph companies lies, as has been intimated, in the increased danger to travelers. And it must be remembered that the advocates of legislation do not ask merely that a second line may be placed on railroad routes. Their whole theory, their proposed act, and the statutes to which they refer, provide for an unlimited number upon each railroad.

It needs no testimony to show that the erection of poles is a source of danger on a track. And this is at present the mode of using wires. It is also the mode adopted by those who ask for legislation. They are dangerous as possible objects of collision, as obstructions to vision and as distracting the attention of locomotive engineers. By falling they have caused fatal accidents; and more frequently such accidents have been narrowly escaped. A long list of casualties has been furnished to the Board in a report from the road department of the Boston & Albany Railroad Company (Note B), but without any such record, common sense would show the possibility of trouble from this source. It is said that all these accidents were not reported to the Board when they occurred. Some of them were not required to be returned. But the question is not whether they were made known, but whether they occurred, and are liable to occur again. The public are not to be deprived of their right to be protected against a danger, because the servants of a corporation failed to make it known.

It is asked, if one line is permitted, why not more. Simply because two obstructions on a road are more dangerous than one: and danger increases in more than arithmetical proportion with the increase of obstacles to vision. Or if an additional number of wires be used on each pole, then the danger of falling, especially when loaded with snow or ice, is increased. The number of poles on every road should be reduced to a minimum. It is now proposed to increase the number indefinitely.

It is said that a few roads have more than one line, and if this causes danger the second line should be removed. If the second line is not needed, this ought to be done; but its existence is no reason for forcing upon the road a third and fourth, and an unlimited number of lines, each of which is confessedly more or less a source of peril. Especially would this be unjust when the roads in question are already contemplating the removal of the extra lines.

It is said in answer to the objections of railroad men, that wires may be buried underground. For the purpose of this case it might be enough to say that no legislation has been proposed here, or adopted in other states, requiring such a disposition of wires. But the Board has devoted some time to considering the question whether this is practicable. The problem is interesting not only from its bearing upon the matter before us, but because it concerns the safety of our streets, now impeded and endangered by the almost intolerable nuisance of telegraphic poles and wires. It is well known that in various places, especially in large cities,

1. The chief authority for the exclusive quality of Congressional legislation is found in Prigg *v.* Pennsylvania, but the decision by no means requires the claim. The doctrine of the case on this point is much weakened by the dissent of three judges, including the chief justice. The controlling motive of the majority seem to have been an excessive and superstitious veneration for that portion of the United States Constitution relating to the return of fugitives, which made a state act in aid of Congress appear like the presumptuous crime of attempting to steady the ark. The decision itself, which set aside a statute that would nullify a clause in the Constitution, and an act of Congress is by no means an authority for setting aside a state law consistent with an act of Congress.

Digitized by Google

telegraphic and telephonic wires have been laid underground. As early as 1837, Prof. Wheatstone's subterranean wires were at work between London and Liverpool. And the first important line in America was in part laid under the earth. Movements now pending for subterranean construction in New York, Philadelphia, Washington and Boston, will throw much light upon this question. Inquiries were addressed to the representative of the Western Union Telegraph Company, and a very full and interesting reply was made in print, from which extracts are given in Note A. We believe that the practical work of laying out and operating subterranean telegraphic wires will prove less difficult than is anticipated. Through the courtesy of Hon. Leopold Morse, M. C., we have received additional evidence on this point, afforded by the experience of government officials. A portion of this testimony also will be found in Note A.

The conclusion which the Board has reached on the point is, that it is very desirable that all telegraphic wires on railroad routes should be laid underground; that owing to the expense and to the difficulty of operating and keeping them in repair, this is impracticable now on long routes, although we incline to believe that it can and should be done in the streets of cities. It may be that at some future time the way will be clear for compulsory legislation, forcing all telegraphic wires on railroads to be so laid; but it would be wrong and foolish to order this now when so many hopeful experiments as to insulation and other improvements are in progress, and when so much remains to be learned as to methods.

These views, if correct, dispose of the argument that streets will be relieved by the free use of railroad locations. The relief in any event would be small. The long routes from place to place are not through streets. Wires leading from stations to business centres will still encumber the streets, and would not be diminished in number by the legislation proposed, and they will continue to be sources of annoyance and danger until the law compels their owners to place them underground. Then the streets will be relieved without any legislation as to railroads.

The possibility of burying the wires is considered here, as it affects danger arising from the use of poles. But the dangers of joint occupation of railroads by several companies do not all spring from this source. One chief object of the legislation proposed is to secure the opportunity to inspect and repair wires. It is hardly necessary to point out the inconvenience and danger of such joint occupation by several parties. The ideal of railroad operation is the exclusive use of the track by one managing and operating head. Every departure from this is a source of danger. When there is a necessary exception to this rule, as at grade crossings, it is a misfortune, and is attended with sad results. The presence of anybody who has a right to use the track for any other purpose than its operation is an evil. The presence of several parties is an aggravated evil, and it would be made worse by the fact that they were rivals and enemies, as would often be the case.

The dangers to be expected from joint occupation and divided management of a railroad track are illustrated by a law of this state. When railroads connect, each has a right under certain circumstances to have its traffic go over the other. It would be a convenience to each if its locomotives could pass over the other road. But knowing the dangers that would result, our law wisely forbids this, except by consent of the road to be so occupied. Joint adverse occupation would be a convenience to the corporation, but it is forbidden because it would be a peril to travelers. And in a single instance where the state has departed from this rule more than one fatal accident can be traced directly to this cause. The management of a railroad track should be exclusive and autocratic; not for the sake of the company but for the safety of travelers. It is possible that a law enforcing the use of underground wires might diminish the anxiety of telegraph men to build on railroads. It certainly would not remove the objection of railroad managers to having their locations occupied by independent and sometimes hostile parties. The necessity for occupying the track for inspection and repairs would still be a source of annoyance and peril. We repeat that sole and exclusive tenancy is the safe rule. This is hardly violated when by agreement the railroad company allows one company the use of its tracks, by which it conducts a joint business with the railroad company, each lending the other its wires on occasion, and working in the harmony of partners, but with inspection and repairs controlled by the railroad authorities. The rule would be at an end if an unlimited number of such companies were allowed to force their way upon the track.

It seems that the call for this legislation is not an existing practical evil, so much as the theoretical objection to what is called a monopoly. And this feeling is strengthened by the fact that one company, the Western Union, has exclusive contracts with many railroad companies in this state. But zeal against monopoly will not blind wise law-givers to the dangers that would arise from the indiscriminate use of railroad tracks by telegraphic lines. The motive of the Western Union is selfish, but the result may be beneficial to the public. And the railroad companies in securing to themselves immunity from loss promote the public safety.

It is hardly necessary to say that the exclusive contracts are no bar or hindrance to legislation. The views of the Board as to an alleged preference given to the contracting company in the distribution of telegraphic material are given in Note C.

In all of these contracts the exclusive claims are limited by the words: "So far as the company may legally refuse"—"So far as may lawfully be done"—or the like. And if these exceptions were not expressed they would be implied by law. No railroad company can bind itself to refuse facilities which by common law, or by statutes, are secured to any applicant. The state itself cannot secure to one company exclusive telegraphic facilities on a railroad track, as was held in the case already cited.

It is unnecessary to discuss this view of the subject, or to quote the cases in which an exclusive grant of a right to one railroad route has been held to be void, because no one will contend that any possible contract with the railroad companies of this state could hinder the Commonwealth from granting a right of way to other parties. No Massachusetts corporation claims the power to nullify in advance a state law. And this question should be considered precisely as if no such contracts had ever been made.

But if the Board is correct in its views, each railroad company without any contract upon the subject, would still refuse a second telegraphic line, and would act rightly in so doing. There is no difference in action between the companies that have contracts with the Western Union and those that have not. A company cannot bind itself not to admit telegraphic rivalry if public interests shall be found to demand it. A company without any contract should refuse telegraphic rivals if the public good demands such a refusal. It is an error to consider the exclusion of rival lines as an unjust preference to the first occupant of the track. The railroad reason for having a telegraphic line at all is the need of having it for the due operation of the railroad. Its reason for not admitting a second line is that it is not needed for the road, and would be dangerous to its customers. The commercial use of it, however great, is, so far as the railroad is concerned, incidental. In bargaining for such mercantile use, the railroad company obtains wires for its own use cheaply and conveniently.

Moreover it obtains for the public such accommodation as could be gained in no other way. On the Old Colony Railroad, for instance, 133 places, some of them wholly insignificant, are under the contract furnished with telegraphic facilities and enabled to reach all parts of the continent. Their gross annual receipts average only $144.03. This accomodation for the public could be gained in no other way than by the present system. The roads need one operator at each place; and by combining with the telegraph managers and by sharing the expenses of good and poor places, can furnish all with facilities. On another road, the Boston & Maine, the returns show at certain points receipts for the month of June, 1884, $5.90, $2.01, $1.50, $0.50. Only by the system which is called a monopoly could these telegraphic offices have been maintained. And few as the messages are, the possibility of sending them may have been of priceless worth to some of the senders.

In many small stations there is room for one operator, but not for two, least of all for two or more rivals. For it need hardly be said that two hostile operators would need more than twice as much room as one operator. Sharing this small local business with an indefinite number of parties would make it worthless, and it would cease to exist. And so, the good of the people would be sacrificed to the selfish demands of corporations. The people of these places will need more than the word "monopoly" to persuade them that for them the system is not a good one.

If it is said that the motives of the railroad corporations are also selfish, the answer is that the legislature should consult, not the motives of any corporation, but only the welfare of the public. A selfish company that promotes the welfare of the community should be encouraged. A selfish company that hinders it, should not be encouraged. And certainly a great public convenience should not be cut off simply because it is also a convenience to certain corporations.

If it is asked, how the monopoly made possible by this exclusive use of tracks by one company is to be avoided, the answer is:

1. No monopoly exists. There are in operation to-day four companies connecting between New York and Boston.

2. No monopoly ever existed arising from the privilege of using railroad locations. The highways of the state furnish, under the law, avenues for telegraphic communication. Its old turnpikes are especially available, and have been freely used. If monopoly ever existed it is not because the entrance of rivals has been forbidden, but because they have sold out to the strongest company.

3. If serious evils are felt arising from the limited number of telegraphic companies, it would be well to remember that unlimited competition is not the only cure for these evils, but that state control may be applied as a remedy. Without fully discussing this point it is enough to say that a great change has taken place in public opinion as to the policy of dealing with monopoly in railroad matters. Formerly, if a railroad 40 miles long ran from A to B and if its charges were too high, the remedy was to build another road between these points, at an expense of more than $2,000,000. And in time, one of these roads was bought up by the other, and the public had to support both. This costly and

Digitized by Google

clumsy method is now discontinued. The quicker, cheaper, and simpler remedy is to make complaint, and procure a reduction.

The power of the courts, acting under state or national legislation, to enforce reasonable prices and facilities cannot be doubted. The doctrine of the United States Supreme Court is that, "when private property is devoted to a public use, it is subject to public regulation." (Munn *v.* Illinois, 4 Otto, 113.) This doctrine, which was applied two centuries since by Chief Justice Holt to the common carriers of that day, has been often enforced against railroad companies, and has been extended by our highest tribunal to warehousemen and to the owners of grain elevators. Without doubt it covers telegraphic companies, which are regarded as "common carriers of intelligence." And in Massachusetts this has been expressly decided in Pierce *v.* Drew (136 Mass., 75-77): "The transmission of intelligence by electricity is a business of a public character to be exercised under public control, in the same manner as transportation of goods or passengers by railroad." The propriety of state supervision and regulation of telegraphs and telephones, with a view to the securing of proper charges for service, is one of great and pressing importance. It is only referred to here to show that it is a more effective way of preventing the dreaded evils of monopoly than the method proposed.

4. If the absence of rivals ever leads telegraphic managers to refuse proper rates, and to deny to the public proper facilities, and if state supervision is not favored, it seems that the best remedy would be found by chartering one or more rival companies upon such terms as would guarantee such rates and facilities. In such charters, conditions could be annexed to the grant securing to the public the facilities to gain which these charters would be granted, and especially securing the public against the buying off, or absorbing, of the new company by the old. Thus assurance could be had that the public good sought should not prove to be a delusion.

The great power of eminent domain, under which a right of way can be condemned without the landowners' consent, whether in the hands of an individual or a corporation, is safe in the hands of the legislature. When application is made for a grant of the right to use this power, the General Court is the best judge of the exigency, of the feasibility of the route, of the responsibility and honest intention of the petitioners. It can decide, among other things, whether the object is to serve the public, or to levy "blackmail" upon existing companies. And this last consideration is especially important regarding the wisdom of a general law for telegraphic companies, because such companies, if so disposed, would have a double chance of extortion,—one with the telegraphic line which they proposed to rival, and another with the railroad line which they threatened to embarrass. (We need not say that these remarks do not apply to the gentlemen who are urging legislation, but the law, if passed, would apply to all persons.)

The rule in this state has been to legislate specially when the right of eminent domain must be exercised. The chief exception, a general law for railroads, was supposed to be demanded on account of the conflicting claims of various projects, and because of the constant draft upon the time of legislators.

Whether this act were wise or not, it has been found necessary to modify it essentially, after great loss to investors, and great injury to landowners. The cause which led to its enactment does not exist in relation to telegraphic companies. Until some exigency is shown, it would seem wise for the representatives of the people to retain in their own hands, the great sovereign power of taking property without the owners' consent, and not to delegate it to any inferior tribunal,—least of all, to intrust it to the interested parties.

It has been suggested that telegraph companies might be authorized to take land near the route of railroads, if it were not thought advisable to place them on the location. This question only arises now as a means of avoiding the danger of intruding upon railroad locations. No proof has been offered of an exigency for such a law, or of any difficulty in obtaining a right of way by bargain. The Board, therefore, does not discuss this scheme, which certainly would be far preferable to one encumbering our railroad tracks with new sources of danger. But having regard to the safety of the traveling public, the Commissioners decidedly decline to recommend any general law allowing the compulsory occupation of railroad locations for telegraphic purposes.

To persons not familiar with railroad operations, the objections of railroad managers to the proposed legislation may seem exaggerated; but so do many of their precautions against possible accident. Small obstacles, slight acts of negligence, errors apparently trivial, produce consequences out of all proportion to their apparent importance. Nothing is more common than to hear rules of precaution denounced or ridiculed by the very men who, after a fatal casualty, condemn railroad managers for not enforcing those very rules more strictly. Exceeding caution has been stimulated by many sad disasters. While the public rightly holds railroad managers to extreme care in the transportation of passengers, it should be willing to listen to them when they ask that they may be allowed to carry their passengers safely.

THOMAS RUSSELL,
EDWARD W. KINSLEY,
EVERETT A. STEVENS,
Railroad Commissioners.

December 31, 1884.

(Notes A, B and C, forming an appendix to this report, will appear in our next issue.)

TELEGRAPHIC COMMUNICATION WITH MOVING TRAINS.

Over a hundred guests availed themselves on February 15th of invitations extended by the Phelps Induction Telegraph Co., to witness a practical test of Lucius J. Phelps's system for electrical communication with a moving railway train. The necessary appliances have been made on the Harlem River branch of the New York and New Haven R. R., and the visitors were conveyed by special cars to its junction with the main line at New Rochelle, N. Y. Upon the down trip to the Harlem river terminus, many passengers availed themselves of the company's request, to write messages addressed to themselves, which were placed in sealed envelopes and handed to the station operator, to be subsequently telegraphed to the moving train on its return trip to New Rochelle.

The system by which communication is established is based upon the familiar principle of induction. The main line consists of an insulated wire, placed in a continuous protecting box, located midway between the rails. The experimental circuit now in use is 12 miles in length. For this a battery current of about 1½ ampères is employed.

The train apparatus is connected in an induction circuit composed of 90 convolutions of No. 14 copper wire, contained in a 1¼ inch rubber hose, the whole passing through a two inch gas pipe, suspended about seven inches above and parallel with the track wire, continued through the body of the car above. The total length of this wire is about 1½ miles, and that portion of the coil placed near the track is extended as far as the dimensions of the car will permit in order to obtain the best possible effect. The car circuit is actuated by a 5-cell Leclanché battery, one jar of which is used for the local sounder. The induced pulsations from the track are conveyed to a very delicate polarized relay, so arranged by Mr. Phelps as to be practically unaffected by the jar of a moving train. The current passes through this relay, the front contact of a pole-changing key, and a "buzzer," the continuous humming of which is divided by the key into Morse characters. Although it has been found possible to utilize a relay for receiving purposes at the terminal stations, a heavy battery was required on the car, consequently a telephone has since been substituted for the use of the receiving operator which serves the purpose admirably.

Quite a number of experts, perfectly familiar with the Morse alphabet, loitered about the instrument compartment, to hear the messages come in. Among them were A. S. Brown, Gerritt Smith and George A. Hamilton of the Western Union, Henry Van Hoevenbergh and Wm. Maver, Jr., of the Baltimore and Ohio. They were perhaps disappointed in hearing only the address of a single message "J. D. Barton." All of these gentlemen were however so thoroughly accustomed to temporary failures of new apparatus, that they did not question the eventual perfection of the system. Suggestions as to faults were freely made. The jarring of the car and the fluctuating distance between the car and track circuits were mentioned, while the inventor attributed the difficulty to undue strength of the main battery. Had a telephone been used as a receiver on the car it was generally thought that the messages might have been read by the operator without difficulty. Transmission from the car to the station proceeded without apparent interruption during the trip. It was said that the system had been working satisfactorily during the previous two weeks, and those present were requested to make a future examination of its merits.

ELECTRICAL REGULATION OF TEMPERATURE.

A very interesting practical demonstration of the application of telemetry, has recently been made at Rev. Dr. Paxton's church on West 42d street, between 5th and 6th avenues. During the past year $60,000 have been spent upon the renovation of this edifice, and special attention has been devoted to the ventilating and heating apparatus. In order to obtain a full supply of fresh air, a ventilating shaft of solid masonry was erected at the northern extremity of the building. By a series of shafts, operated by cranks in the sexton's pew, currents of warm or cold air could be admitted as required through inlets arranged under the pew entrances. Ordinary thermometers were suspended in different parts of the church, but as these were not accessible at all times, without disturbing the services, Mr. Heber R. Bishop, one of the leading trustees, suggested the introduction of Hewitt and Clarke's system as applied to telethermometers, described on page 265 vol. iii of

Digitized by Google

this journal (December 1884). The transmitting thermometers are located on the right and left floors and corresponding galleries, and electrically connected with indicators and recorders placed in the sexton's pew, marked respectively, floor right, floor left, gallery right, and gallery left. It is obvious that a single degree of change in the temperature is at once registered, and the desired regulation made accordingly, thus preserving equable warmth throughout the building, which has heretofore been a difficult problem especially where a large number of people are assembled. Considerable amounts of money are frequently expended upon the sanitary fittings of fine buildings of this character, without accomplishing one of the most desirable results, that is, providing for the comfort of the occupants by protecting them from those violent changes so frequently prejudicial to the health of the strong as well as the weak. The adoption of improvements of this character should be heartily encouraged.

TELEGRAPHERS' BUILDING LOAN AND SAVING INSTITUTION.

In order to foster the accumulation of wealth, and provide unquestionable investment for the same, some of the most reliable gentlemen connected with the service of the Western Union Telegraph Co., have organized, and secured a charter for the "Serial Building Loan and Savings Institution." It is based upon a plan similar to those which have been so successful in Philadelphia, and is incorporated under the laws of New York and New Jersey. Its avowed objects are the encouragement of savings, and the assistance of its members in acquiring homesteads. The shares have been fixed at a par value of $200 each, upon which monthly installments are paid of $1, each. The money thus accumulated is loaned to stockholders only at 6% interest payable monthly, one share of stock being pledged for each $200 borrowed. Statistics show that stock in building associations of this character reaches its par value in from eight to ten years, according to the demand for loans. These associations offer perhaps the best and safest possible investment for wage earners. Although this institution has been organized by and among telegraph men, its shareholders are not restricted to that fraternity. Among the officers are, James Merrihew, President, M T. Wilbur, Treasurer, William B. Marsh, 172 Pearl street, Secretary. Any of these gentlemen will furnish further particulars to those seeking information.

THE NEW YORK ELECTRICAL SOCIETY.

At the regular meeting in the Cooper Union building, Feb. 25th, Henry A. Sinclair, of the U. S. Ordnance Ground at Sandy Hook, gave a very interesting account of the practical application of the Boulanger chronograph.

This is the instrument by which the velocity of shot is tested. It has been in use by different governments for 10 years. Mr. Sinclair had prepared a square wooden box about 10 feet long to one end of which was affixed a target. When a revolver was fired at the other end of the box, the bullet cut a wire at the muzzle of the pistol and another wire in the target which the bullet struck. The first wire cut a circuit and liberated a weight in the chronograph. Another circuit was cut by the wire in the target, causing the falling weight to be caught and marked, by which means the calculation was established. The pistol was of 45-calibre and the first shot showed a velocity of 156 feet a second the second shot 207 feet a second, the difference being due to the variance in the amount of powder in the cartridges. Mr. Sinclair said that by the chronograph a velocity of the five thousandth part of a second could be measured.

It is now used, he explained, in testing the velocity of the heaviest shot, and had resulted in the most accurate knowledge of the capacity and limits of different kinds of ordnance. Had Commander Worden, of the Monitor, had the benefit of these results, Mr. Sinclair said, he might have increased his charge of powder with impunity, so that one of his guns would have sent a ball tearing through both sides of the Merrimac. The heaviest guns on one of the Italian men-of-war recently sent a 2,200-pound shot at a velocity of 1,800 feet a second with a force sufficient to crack and break a 24-inch plate of combined steel and wrought iron. This was the heaviest defensive armor that has yet been prepared for ironclads.

At the next meeting of the Society, March 11th, the annual election of officers will take place.

ANOTHER TIME TELEGRAPH PROPOSED.

A public exhibition has been given at 18 Broadway of a system for the distribution of standard time by the use of electrical mechanism, devised by C. A. Mayrhofer of Vienna. Practically the proposed plan is to secure the same results as have been so well accomplished by the Time Telegraph Co., in this city. A rival organization is wholly unnecessary, and may perhaps be considered an evil in this particular field. Experience shows that there should be but one system of standard time, which when generally recognized, even if wrong, is preferable to two or more systems varying only slightly from each other. Fortunately there can be little encouragement for a new enterprise of this kind, and the public can remain in comparative contentment under the existing arrangements which have proved very satisfactory up to the present time.

DUPLEX LITIGATION IN ENGLAND.

Dr. Muirhead brought an action sometime since against the Direct United States Cable Co., Limited, to recover the amount claimed to be due for rental of his patented duplex system of telegraphing for a certain period during which, in consequence of defects in the cables, the system could not be worked. The case came up on January 19th on an appeal of the defendant company from the decision of Mr. Baron Huddleston in favor of complainant. Having heard the arguments of the counsel for the defendants, that the cables, though slightly defective, would yet carry messages on the simplex system, the Master of the Rolls expressed himself clearly to the effect that the fault was in the company's cable and not in the duplex system, which was now as good as ever, and held that Mr. Baron Huddleston was right in his decision. Lords Justices Cotton and Lindley concurred, and judgment was given against the appellants.

EXAMINERS' REPORTS ON THE PHILADELPHIA ELECTRICAL EXHIBITION.

The reports of the various boards of examiners, appointed in connection with the Philadelphia Electrical Exhibition, are being published, as completed and authenticated, first as supplements to the *Journal of the Franklin Institute*, and afterwards separately in pamphlet form. They may be obtained upon application to Secretary W. H. Wahl, at prices varying from 10 to 25 cents each according to size.

ELECTRIC LIGHT AND POWER.

Domestic.

The Houston (Tex.) *Chronicle*, of Dec. 31, in detailing the storms of the previous night said: "The lightning prostrated several electric light poles in the First, Fourth and Fifth wards, smashing lamps and globes. At the electric light works the lightning played havoc with the plant, burning three dynamos out in two nights. Two extra or reserve machines were also struck by lightning, putting out every arc light in the city."

An electric light plant is to be established in North Attleboro, Mass., the requisite number of subscribers having been obtained.

The incandescent electric light is meeting with a large and increasing field of usefulness in flour mills, where it has many points of advantage. The Park, Eagle and United States mills of St. Louis are among the latest to adopt it.

The following are the various bids submitted by the gas companies of the city of Brooklyn for the public lighting of that place during 1885:

	Street Lamps.	Public Buildings.
Brooklyn Gas Light Co., each per annnm..	$19.80	$1.50 per M.
Williamsburgh Gas Light Co., each per annum	21.75	1.75 "
Peoples; Metropolitan; Nassau and Citizens Gas Light Company, each per annum.	22.00	1.75 "

For the first time in the history of Brooklyn proposals were made to supply arc illumination for the streets. The propositions were handed in by representatives of the Brooklyn and Municipal Electric Lighting Companies—the former to furnish the Western and the latter the Eastern Districts of the city with such lights as might be awarded them.

The Pennsylvania Railroad Company is making experiments at its shops at Altoona with electric lights for use in its passenger cars. The experiments have progressed so favorably that it is believed that within a few months the electric lights will be introduced into all the passenger cars on its various lines.

The Daft Electric Light and Motor Co. has purchased the Gunther property at Ravenswood, Long Island, and will immediately build shops.

Isolated plants have been placed in the new Montezuma Hotel at Las Vegas, N.M., and Henck's Opera House at Cincinnati, which will be operated by the Westinghouse automatic engine.

Foreign.

Temesvar is the first city in Europe to have its streets lighted throughout by electricity.

Fire in the premises of the Edison Electric Light Co. on King William street, Hamilton, Ont., recently caused $5,000 damages.

Digitized by Google

An electric light plant is being put down by Messrs. Heenan and Froude of Manchester, for lighting railway carriages on the Great Eastern Railway. Seven trains have been running since the 1st of October without a hitch. The dynamos are driven by Messrs. Heenan & Froude's high-speed spherical "Tower" engines, engines and dynamos being 3 ft. 3 in. long over all, by 13 in. wide and 2 ft. high. They are placed on the locomotive boiler behind the dome, and clear of the side view of the driver, as it occupies a centre position on the boiler. Steam is taken from the dome, and exhausts by the chimney. The engine, which develops 10 h. p. and makes a thousand revolutions a minute, weighs only 57 lb.; and the dynamo, engine and bed complete weigh 3½ cwt. The wires and lamps are so arranged as not to prevent oil lamps from being put in at a moment's notice in the event of a train being divided from the main, and run on to a branch line; but the Great Eastern Railway Co. contemplates applying the electric light to the whole of its trains.—*Mechanical World* (Manchester).

It has been decided to light the Imperial Palace, the Court Opera House, and the Burg Theatre of Vienna with electric lights. The palace will be illuminated with 5,000 lights, the Opera House with 4,000, and the Burg Theatre with 3,000. The system to be employed is the Turettini patent.

A central station is being established at Antwerp for the purpose of supplying 6,000 incandescent lamps. The dynamos are of the Gulcher pattern, the current being conveyed by underground cables of the Callender system.

A petition has been presented to the Paris Municipal Council requesting the Administration to study suppression of gas in the schools and colleges, and the adoption of electric light. If this is found impracticable, the petitioner, M. Lyon-Alemand, advises a return to oil lamps.

PERSONAL MENTION.

John Benjamin Page, for many years the manager of the Western Union office at the Metropolitan Hotel, has resigned his position, and returns to Canada to engage in the leather business with his brother at Kingston, Ont.

The King of Portugal has recently conferred the honor of Cavalliero do Christo on Mr. Alan Danvers, engineer and manager to the Edison-Gower-Bell Telephone Company at Lisbon.

William Cassils, an old telegrapher—now a Director of the Montreal Telegraph Co.—is one of the incorporators of "The Herald Newspaper and Printing Company," of Montreal.

Mr. Mackay, of the Mackay-Bennett Cable and Postal Telegraph Company, is a native Canadian, and hails from Cobourg, Ontario.

Joseph E. Fenn has been appointed Electrician of the Southern division of the Western Union Telegraph Company, with headquarters in New York city.

SUBMARINE CABLES.

The Dominion government is being petitioned to lay down a telegraph cable between Amherst Island, Lake Ontario and the mainland.

The annual report of the Anglo-American Cable Co., indicates that a large reduction in the revenues of the cable pool is expected to result from the competition of the Commercial Cable Co.

THE TELEGRAPH.

Domestic.

The reports of the amalgamation of the Postal and Bankers and Merchants' companies are daily growing more definite.

Brooklyn has over 3,000 miles of telegraph wires within her borders, and ten miles of cables, all overhead. The city owns 190 miles of this in fire department wires, and 90 in police department wires.

The Phelps Induction Telegraph Company has filed its certificate of incorporation in this city. Its objects are to manufacture instruments and apparatus to be used in telegraphing to and between railroad cars while in motion.

The Baltimore & Ohio Telegraph Company will make strenuous efforts to obtain equal privileges with the Western Union on the lines of the Pacific railways. These roads having been liberally subsidized by the government, an appeal will be made to Congress, provided a satisfactory arrangement cannot otherwise be made.

The Railway Telegraph and Telephone Co., has been incorporated in New York state. Its object is the application of electricity to communication with moving trains, and similar purposes. Thomas A. Edison, S. Bergmann and Charles Batchelor are among the incorporators.

Under the pressure of the recent increase in the number of fires that has seriously crippled the force, the New York Fire Commissioners have directed the Superintendent of the Telegraph to report a plan for transmitting alarms that will relieve the companies from the necessity of hitching up for alarms from remote sections of the city. The resolution sets forth that under the present system of sending all fire calls to every company in the department the men are often unnecessarily deprived of needed rest.

Foreign.

The expenditure upon Canadian government telegraph lines for 1884 was $127,364. The government lines in operation in the North-west extend 620 miles from Qu'Appelle station to Edmonton, 537 miles, and from Clark's crossing to Prince Albert, 83 miles. Some portions of these lines require repairs and others rebuilding.

THE TELEPHONE.

Domestic.

Annual meetings of the Iowa Union Telephone and the Iowa and Minnesota Telephone companies were held recently at Davenport for the election of officers. The former company's territory covers 50 counties in Iowa, with 1,974 miles of poles and 2,700 miles of wire.

It is said that residents of Lowell, Mass., are represented in the Erie and New England Telephone companies, to the amount of $3,000,000. The Erie company had in use 8,999 telephones Dec. 31, a loss of 154 during the month.

Foreign.

The Bell Telephone Co., of Canada, will endeavor to have the recent adverse decision in the telephone suit set aside. The patents for battery transmitters are not affected by it, and any infringements upon them will be prosecuted.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER *by* Pope & Edgecomb, *Solicitors of Patents for Electrical Inventions*, 59 *Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From January 27, to February 17, 1885 (inclusive).

Alarms and Signals:—*Indicator for Base-Ball or Cricket*, W. Williams, 311,278, Jan. 27. *Thermostat*, G. R. Williams, 311,933, Feb. 10. *Alarm Mechanism and Apparatus*, W. M. Pease, 312,504.

Clocks:—A. S. Crane, 311,234, Jan. 27. *Apparatus for Synchronizing*, J. A. Lund, 312,482, Feb. 17.

Commutators:—*Cut-out for Apparatus*, S. H. Short, 312,242, Feb. 10.

Dynamo Machines and Motors:—*Dynamo*, F. G. Waterhouse, 311,547, Feb. 3. *Armature for*, F. K. Fitch, 312,111, Feb. 10.

Conductors, Insulators, Supports and Systems:—*Skeleton Tower*, J. S. Adams, 311,165. 311,166, Jan. 27. *Cable*, H. A. Clark, 311,174; W. R. Patterson, 311,521. *Method of Repairing Same*, same, 311,522. *Means for Hanging Same*, same, 311,523. *Circuit Connection*, T. T. Smith, 311,616, Feb. 3. *Circuit Opener*, W. H. Sawyer, 311,681. *Circuit*, W. A. Shaw, 311,682. *Apparatus for Filling Cable Pipes*, W. R. Patterson, 311,913, Feb. 10. *Joint for Arc-lamp Cables*, same, 311,914. *Insulated Conductor*, W. P. Thomas and E. J. Frost, 312,405, Feb. 17. *Wire Splicer*, P. A. O'Malley, 312,580. *Circuit for Systems Electric Lighting*, W. M. Thomas, 312,589.

Galvanic Batteries:—*Porous Cup*, C. P. Orne, 311,516, Feb. 3. *Battery*, A. M. Young, 311,630; I. L. Roberts, 311,853. *Carbon Battery Element*, same, 311,852. *Galvanic Element*, A. Dun, 312,339, Feb. 17. *Apparatus for Charging and Emptying Same*, same, 312,340.

Lamps and Appurtenances:—*Lamp Fixtures*, E. Weston, 311,338, Jan. 27. *Portable Lamp*, T. T. Smith, 311,617, Feb. 3. *Arc-lamp*, B. B. Ward, 311,546; C. F. Brush, 312,184, Feb. 10. *Feed Regulator for*, S. H. Short, 312,243. *Incandescent Lamp*, O. B. Fahnehjelm, 312,452, Feb. 17. *Hanging Balanced Lamp*, T. T. Smith, 312,394. *Cut-out for Lamps*, W. M. Thomas, 312,529. *Apparatus for Treating Incandescent Carbons*, E. A. Colby, 312,552.

Ignition:—*Knob for Gas-Lighting Apparatus*, F. Lane. *System of Firing Turret Guns*, T. R. Timby, 312,231, Feb. 10. *Torpedo*, T. Nordenfelt, 312,579, Feb. 17.

Miscellaneous:—*Device to Assist Hearing*, L. Ehrlich, 311,180, Jan. 27. *Exercising Apparatus*, J. H. Shaw, 311,381. *Demonstrative Electrical Apparatus*, J. D. Culp, 311,725, Feb. 3. *Rheostat*, J. Doyle, 311,820. *Toy Swing*, M. Bacon, 312,178, Feb. 10. *Anti-Magnetic Watch-Case*, C. K. Giles, 312,458, Feb. 17. *Electro-Magnetic Comb*, W. T. McGinnis, 312,487. *Instrument for Electrical Reporting*, W. M. Pease, 312,503. *Electro-Magnet*, E. F. Recordon, 312,511.

Protectors:—*Telegraphic and Telephonic Instrument Protector*, G. A. Cardwell, 311,957, Feb. 10.

Railways and Appliances:—*Automatic Time Signal for Railways*, F. H. Young and F. I. Davis, 311,705, Feb. 3. *Indicator for Switches*, G. Otte, 311,846. *Railway Car Telegraph*, L. J. Phelps, 312,506, Feb. 17. *Railway*, L. Daft, 312,557.

Storage Batteries:—*Method of Preparing Elements*, A. K. Eaton, 311,236, Jan. 27. *Secondary Battery*, S. Phillippart, 311,445, Jan. 27; J. W. Swan, 312,599. Feb. 17.

Telephone Systems and Apparatus:—*Annunciator*, W. A. Childs and F. Shaw, 311,472, Feb. 3. *Connecting Cord*, W. H. Sawyer, 311,611. *Circuit and Apparatus*, L. A. Berthon, 311,944, Feb. 10. *Memorandum Holder for Telephone Boxes*, J. F. Gilliland, 311,977. *Transmitter*, J. H. Guest, 311,979; C. A. Randall, 312,160, 312,161; H. E. Waite, 312,409. *Receiver*, C. A. Randall, 312,162. *Telephone*, 312,365, Feb. 17; 312,366; W. R. Miller, 312,492; T. Wallace, 312,533. *Switch-board*, H. E. Waite, 312,410.

Telegraphs:—*Printing*, J. E. Wright and J. H. Longstreet, 311,218, Jan. 27. *Repeater*, J. Kolzer, 311,330. *Combined Audible Stock Quotation System and Fire Telegraph*, 311,756, Feb. 3. *Audible Quotation System*, same, 311,757.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

NEW YORK, APRIL, 1885.

THE McDONOUGH TELEPHONE CLAIM.

THE first patent of Alexander Graham Bell in which was shown and described an apparatus capable of being used as a speaking telephone was issued on the 7th of March, 1876. Within the next few years a number of applications for patents were made by different persons, who claimed to have invented prior to the date of the patent of Bell, either the generic speaking telephone, or some essential portion of the apparatus necessary for telephonic transmission. On the 26th of March, 1878, interference proceedings were instituted by the Commissioner of Patents to determine the question of priority as between the respective claimants.

For the benefit of those not versed in the technicalities of legal procedure, it may be well to explain that an "interference" is a proceeding in accordance with the patent laws of the United States, which is resorted to by the Commissioner for the purpose of hearing and determining the question of priority of invention between two or more parties claiming the same patentable subject-matter, so that the controlling patent may issue to the party who is legally the first inventor. It may be added that the fact that one or more of the parties has obtained a patent, does not operate to prevent the interference, for although the Commissioner has no power to cancel a patent which has once been granted, yet if he finds one of the subsequent contesting applicants to have been the first inventor, he may grant him a patent also, and thus give him a standing which will enable him to prosecute infringers in the Federal Courts.

Subsequent to the original declaration of interference, other parties appeared and were included in it. Owing to the great number of contestants, 14 in all, the taking of the testimony occupied a great length of time, and it was not until the 21st of July, 1883, more than five years after the original declaration, that a decision was rendered by Mr. Church, the Examiner of Interferences, in which priority in respect to most of the essential features of the invention was awarded to Bell, thus confirming his patent against the claims of the various contestants. The most important exception to the general tenor of the decision, was in respect to the electro-magnetic diaphragm receiver, which as is well known forms an almost indispensable part of the practical telephone. On this point, priority of invention was awarded by the examiner to J. W. McDonough, whose application was filed on the 10th of April, 1876, but a short time after the grant of Bell's patent, and before the invention had attracted any particular attention, even among electricians. The decision of the Examiner of Interferences, was appealed to the Board of Examiners-in-Chief, and this tribunal reversed the decision of the Examiner of Interferences, as to the receiver and awarded priority to Bell. The final appeal to the Commissioner was then taken, who has recently rendered his decision sustaining the view taken by the Board.

The award of priority by the Examiner of Interferences to McDonough in respect to the invention of the telephone receiver, has given rise to a wide-spread curiosity to know something of the history of his invention, and we have, therefore, in another place reproduced an article recently published by Professor E. J. Houston of Philadelphia in which the claims of McDonough and the history of his invention are concisely set forth and illustrated with facsimiles of his sketches and drawings of his apparatus. It is proper, however, for us to say that we do not coincide with Professor Houston in many of his opinions, either in respect to the speaking telephone in general, or to the pretensions of McDonough in particular, whose work at best can fairly be said to be little more than a crude experimental reproduction of the well-known apparatus of Philipp Reis. His transmitter was essentially that of Reis; his receiver was a parchment membrane stretched over a ring or hoop, and having an armature fixed upon it in proximity to the poles of an electro-magnet. There is perhaps no reason to doubt the general truth of the statement of the witnesses in behalf of McDonough as to his experiments in June, 1875. This testimony goes to prove that tunes were recognized, together with some words of the tunes, but it is familiar to those accustomed to experimenting with telephones, that a sound resembling that of a well-known tune irresistibly suggests to the mind the accompanying words, a mental deception which it is extremely difficult to avoid. The apparatus shown in McDonough's application for a patent is substantially a Reis transmitter placed in circuit with the diaphragm receiver above mentioned. Professor Houston says that "there appears to be ample testimony by the most able experts that apparatus constructed in accordance with McDonough's specification of April 10, 1876, can and does clearly transmit intelligible articulate speech."

At this point, we decidedly take issue with Professor Houston. We think it not improbable that a few words and perhaps even sentences may have been successfully transmitted by means of a McDonough transmitter and a magneto-receiver, that is to say a receiver having an electro-magnet with a permanently magnetized core. But without such a receiver, it is probably quite safe to say that an intelligible sentence has never been received, even by an "expert," from the transmitter described in

Digitized by Google

McDonough's specification. But McDonough neither invented nor described the diaphragm receiver with a magnetized core, in other words, the true magneto-receiver. This was first made and publicly exhibited in this country by Gray in July, 1874, and in England in August of the same year. In a somewhat different form it is shown and described in Bell's patent of March 7, 1876, and the credit of the discovery is due either to Gray or Bell, certainly not to McDonough. Hence even if it were true, as Professor Houston suggests, that the real improvement which converted the apparatus of Reis into a commercially valuable organization consisted merely in the invention of a more suitable receiver, it was not McDonough who put the finishing touch to the invention. Professor Houston speaks of the "generally acknowledged fact that the Reis transmitters operate very satisfactorily when combined with magnetic diaphragm receivers" as if there were no question about it. We think that the spectacle of an average citizen trying to order his Sunday dinner from the market-man by means of a Reis transmitter and a "magnetic diaphragm receiver" would tend to give a new meaning to the word "satisfactorily." Moreover, if we take the transmitter in any of the different forms in which it was constructed by Reis, without the aid of the additional inventions employed in connection with the modern magnetic receiver, it would be utterly impossible to converse through the apparatus with sufficient certainty to render it of any practical use, in a circuit more than a few feet in length. In order to do this we must add to the microphone transmitter—or Reis transmitter as Professor Houston would probably prefer to call it—an induction coil, otherwise we cannot transmit intelligible sounds through ordinary distances.

The opinion of Commissioner Butterworth, which is final so far as the Patent Office is concerned, is given in full in another column. He decides in favor of Bell, on the well established principle that to defeat a patent already granted, the claimant for priority must prove a prior completed invention, which McDonough in his judgment, has failed to do. We do not see how he well could have decided otherwise, for the issue calls for a receiver "whereby sounds thrown upon the line may be reproduced accurately as to pitch and quality," and it certainly does not appear from the testimony that, prior to the date of Bell's patent, the fact was ever experimentally established by McDonough, that his receiver would reproduce "quality" of sound.

It is probable that the matter will not be allowed to rest with this decision, but will ultimately make its appearance in some form in the Federal Courts.

THE VICISSITUDES OF INVENTION.

At the incipient stage of the electric light "boom" a large investor in gas stocks, panic stricken by the sudden decline in those securities, sought advice as to whether he should hold on or let go. With considerable anxiety he solicited the views of a friend, who was more experienced in electrical matters than himself, who said: "I don't know whether it is a fact, that the anticipated competition of the electric light has depressed gas stocks, but if you are sure of that point, and have plenty of money to invest, I should say buy all you can get hold of at panic prices."

There is a field for the electric light, but it has not, nor will not drive out gas; neither will gas supersede petroleum nor oil lamps render the candle obsolete. Although the candle still figures in parlor entertainments as "the light of other days," the gross amount of its manufacture increases yearly. Public opinion is not a reliable prophet. It was predicted that the advent of the railway would make horses a drug in the market. It was not supposed that railways could successfully compete with steamboats. After fighting rapid transit for years in New York city, the horse railway companies have discovered that their profits are larger than they were before the elevated railways were established. It was confidently asserted, even by men who ought to have known better, that the telephone would inevitably supersede the telegraph, and we presume that at this moment certain inventors are toiling hopefully in the belief that the telephone will be adopted for the Atlantic cables, as soon as they can practically demonstrate the feasibility of oral communication through them. Telegraphic history is replete with the curiosities of electrical development. Under the assumption that the dot-and-line characters could not possibly be made with reasonable accuracy by hand, metal type were originally designed for the purpose of manipulating the circuit-breaker automatically. The operator who read "communications" from the paper tape, was allowed a copyist to facilitate his work. After this assistant had been finally dispensed with as a matter of economy, the operator eventually discovered that in spite of the prohibitory orders of the management he could read by sound and copy, more easily and rapidly than he could follow the characters embossed on the tape. With the advent of the House printing instrument, the Morse system was thought to be certainly doomed to early extinction. Anybody could learn to telegraph on a plainly lettered key-board, while the satisfaction of receiving a message, plainly printed, in Roman letters would lead the public to give their entire patronage to the printing lines, which assumed to be "prompt, accurate and reliable." To-day the printed telegram is declared a nuisance in the counting-house, because by reason of its peculiar form it is awkward to file away, while under the derisive appellation of "snake copy" it is heartily detested by every newspaper compositor. Various automatic and chemical devices have had their rise and fall; some have had their advantages, and more their defects, but as a universal and comprehensive system the old fashioned Morse stands to-day practically impregnable. It is the general tendency of improvement to render any device more simple, and automatic; that is, less dependent upon the supervision and immediate attention of man. It is for this reason that we have looked upon the arc-lamp as a comparatively crude device. It must each day be supplied with new points, and consequently receive the personal attention of a "trimmer," armed with a step-ladder and a haversack filled with carbon pencils. It is true that it fulfills its mission, and so did the old hand-brake on railway trains, although every intelligent man knew that the time would come, when a satisfactory power brake would be introduced, under the direct control of the engineer. The balloon affords the means of traveling in

Digitized by Google

the air, yet it is by no means a solution of the ideal problem of aerial navigation. It is rarely that a thoroughly complete invention becomes obsolete. The sailing vessel still holds its own, although its field is becoming narrowed; the Indian canoe of the north-west coast is still the model of the fastest sailing craft. One can recall scores of inventions such as the snow-shoe and the Chinese gong upon which no improvements have been affected within the memory of man, while others perhaps equally meritorious are entombed among the "lost arts."

DEATH IN THE AIR.

In their anxiety to harass existing electrical companies, by forcing them to place their wires underground, other and more serious overhead dangers have escaped the attention of the public press and our legislators.

During the high wind which prevailed in this city and vicinity on February 17th, the following casualties occurred, according to the news columns of the *New York Times:*

Caroline Carlton, of No. 1,450 First avenue, was struck on the shoulder and severely injured by a sign which was blown from No. 400 Third avenue.

William Hawe, of No. 602 West Thirty-seventh street, while passing Thirty-third street and First avenue, was struck with a plank blown from an unfinished building, receiving concussion of the brain.

Sarah Waters, a child, whose parents live in East Twenty-second street, was struck on the head and seriously injured by a sign blown from a liquor store at First avenue and Twenty-sixth street.

Barbara Kaufman, 50 years old, while passing No. 158 Crosby street, was struck on the head by a sign belonging to Lippincott & Co., and was severely injured.

An iron shutter weighing about 150 pounds was blown from its fastenings at one of the upper windows of the tall Mortimer Building, in Wall street, about noon, and it cut a small hole in the iron roof of the Stock Exchange. The noise that the shutter made in falling caused something of a scare in the Exchange.

It appears strange that a journal which has been so active in the instigation of public prejudice against aerial wires, should wholly ignore the far more imminent danger arising from the thousands of signs hung at various heights and positions, often insecurely fastened, and subject neither to official inspection, or any legal restriction which in any manner exacts responsibility from the mechanic who paints and erects them. This lax state of affairs is the more reprehensible for the reason that these signs do not in the slightest degree serve any useful purpose in behalf of the people whose lives are continually threatened by their existence. Neither are they a necessity to their owners. Some of the most important business houses in every city, are devoid of obtrusive signs. The Western Union Telegraph Company denotes its principal office by a modest sign not ten feet from the ground, which a cyclone could not remove. The great business of A. T. Stewart and Company was maintained in its prosperity without a sign of any description on the buildings. Certainly it cannot be necessary for a great newspaper like the *New York Times* to placard its building with large signs in order to assure the public that it continues business at the old stand, and that thankful for past favors it respectfully solicits a continuance of the same. Owners of the finest buildings now erected for rental in New York city, prohibit the display of signs other than the regulation directory upon a panel at the entrance, where each tenant is placed upon an equal footing with the other occupants of the building, and required to have his name inscribed in letters of a specified and uniform size.

We believe the mercantile community would experience a feeling of relief if a general law was passed compelling every firm and individual, to either dispense with signs altogether, or force all of them to adopt a uniform standard to conform for example with the letters used for designating the names of streets on the city lamp-posts. We respectfully call the attention of Senator Daly to the consideration of this question.

WHERE ARE THE ELECTRIC MOTORS?

The electricians, or capitalists and patentees interested in electric motors, who have been for months asserting that electrical transmission of power could be economically applied to the moving of railroad trains, are tiresomely slow in reducing their schemes to practice. Months ago we were told, and the assertion was industriously repeated by the daily press, that Mr. Daft was making preparations to lay electric conductors on the Brooklyn bridge, by which he would at once demonstrate how cheaply and promptly the cars would be moved by electricity. That scheme was suddenly abandoned, without any cause given, and we were then told that Mr. Daft was going to experiment with electric motors on the Ninth avenue elevated railroad. Mr. Daft was wise in his generation in abandoning the Brooklyn bridge, where heavy tractive power is needed, and the exact power used to move cars by cable can easily be ascertained. He has now got official permission to lay down a conducting rail on the Ninth avenue road, but week after week passes and nothing is being done to forward the work. Mr. Field's company has got permission to lay a rail on the Second avenue road, and they also do nothing further in the matter. Come along with your electric motors, gentlemen, the public is waiting for them, and you have roused expectations that ought to be allayed.—*American Machinist.*

Four months have elapsed since President Cyrus W. Field of the Manhattan Elevated Railway, in his annual report suggested the use of electrical motors upon the roads operated by that company. Subsequently the directors formally authorized the executive officers to allow the Second avenue line to be used for experimental purposes. Possibly the editor of the *American Machinist* may have had practical experience in the actual manufacture of machinery, if so he should know that very few, if any establishments exist, where experimental apparatus of this character constructed from new designs, can be completed in three months. In order to relieve his apparent anxiety however, we are authorized to state that a special car built by the Pullman company to be fitted with motors, will be delivered within a month. The necessary quantity of 70-lb. steel rails have been ordered for the central conductor, and the money is ready to pay for them. Whether or not electrical motors will be adopted for service on the elevated railway we are not prepared to say, but the prospects now are that the editor of our esteemed contemporary may avail himself of an excursion on the fourth of July, in a car driven by the agency of electricity on the Second avenue line.

ARTICLES.

THE CONSTRUCTION OF LINES FOR ELECTRIC CIRCUITS.

BY THOMAS D. LOCKWOOD.

(Continued from page 89.)

IRON POLES.

WHILE the use of iron for this purpose is by no means extensive, it is constantly increasing in favor, and will probably become very common in countries where wood is scarce, or where it rapidly decays. Its use is to be commended, even in this country, for lines which pass through parks or private grounds, or through handsome streets where the ordinary wooden pole would be objected to by municipal authorities or property owners, as it is capable of being constructed in many ornamental and symmetrical forms. Of course the cost of an iron pole is much greater, but as a general thing it is more economical in the end to pay a little extra in this way, than to offend the sensibilities of the abutters. If poles formed completely of iron cannot conveniently be procured, a compromise may sometimes be made, by planting a stout cast iron socket, placing therein a strong shaft of timber, to give the desired length, and surmounting this shaft again by an iron top piece, carrying the iron cross-arms. The top piece cross-arms, and insulator pins may be made of gas pipe ; or the cross-arms may simply be short iron bars bolted to the pole, to which may be attached either pins or brackets.

Railroad officials or amateurs connected with railroads, will find that old rails make very good poles, as does also gas pipe ; the latter especially when but a single line is required. Several forms of iron poles are already in use in foreign countries : In Switzerland for example, an iron pole consisting of a conical wrought iron tube is used ; its length varies from 11 to 8½ feet, its diameter at the base is about 2¾ inches, and at the small end about 1½ inches. These poles are set in foundation blocks of stone, the size of which depends on the size of pole which it is to support.

The iron post of W. Siemens is perhaps more extensively used than any other. It is formed in fishing-rod style of two tubes telescoping into one another, the upper one being usually surmounted by a lightning discharging point, while the lower end is secured by four bolts to a buckled iron plate bent or pressed into a dish-shaped form by which great strength is given to it. For a line of not more than three or four wires they form a very elegant support, and are made in sizes varying from 20 to 24 feet long, the average weight being about 185 pounds.

Lieut. James A. Swift in his book "The Practical Telegrapher" describes a very simple iron pole used by the U. S. Signal Service for single wire coast lines. It is of good iron, 20 feet long in the full ; is tubular, having an external diameter of 2¼ inches, and weighs without the attachments about 75 pounds. The pin carrying the insulator is round like an ordinary cross-arm pin, and is fitted in the top of the pole. The most ingenious thing about the pole to my mind, is the arrangement provided for climbing. A hole is made through the tube from side to side about four feet from the top, and in this hole an iron bar about 15 inches long and five-eighths of an inch thick is thrust. A narrow strip of wood some 10 feet long and two by four inches thick, has spikes driven into its sides as steps or foot irons, while two hooks at its upper end are adapted to hang on the cross-bar above. The lower end is prevented from swinging round, by a clamp which clasps the pole. This arrangement being light is easily carried round from pole to pole.

It may be stated here, before we part company with the subject of iron poles that they have an advantage over wooden ones, in that being metal they themselves serve as lightning and leakage conductors ; while they also have a corresponding disadvantage, in that a wire accidentally slackened or freed from the insulator, and hanging loose, will almost certainly fall against the pole and thus form a dead ground, while with a wooden support, in fine weather, the line could be readily worked as well as before.

CROSS-ARMS AND BRACKETS.

If only one wire is to be carried, one of two attachments may be adopted.

The insulator may be fixed to a bracket, and the bracket spiked to the side of the pole a few inches below the top ; or the insulator may be affixed to a pin which is driven in a hole at the top of the pole. When the latter mode is adopted, an iron ring smaller when cold than the top of the pole, should be heated to bright redness and then slipped over the small end to prevent it from splitting. The bracket plan is however preferable, as the insulator and pin when attached to the top of the pole, are apt to be lifted off, when the pole is planted in a hollow, and even on a level there is an upward tendency. Brackets are made of locust or oak, should be painted before attaching to the pole, and are spiked to the poles.

It is better if more than one wire is to be strung, to use cross-arms. These are best made of white pine—and are of four by five stock. They are planed and have their upper corners beveled. The length of a standard cross-arm for two wires is three feet ; for four wires five feet six inches ; and for six wires seven feet six inches. It is usual to make the distance between the insulators 22 inches from centre to centre ; and more than six wires are rarely placed on one cross-arm. The sizes given are for regular telegraph work. For telephone lines the insulators are usually placed nearer together, and as many as 10 or 12 on the same arm.

A thing not always attended to in the United States, is the numbering of poles and wires. Every line of a mile in length, or over, should have its poles numbered and a record of such numbers ought to be kept by a suitable officer. The work of maintenance is thus made much easier, for the location of any trouble can be more clearly indicated. Each wire should also be numbered, and the system of numbering pins should be uniform, so that the bare mention of a pin by its number may at once indicate to the mind's eye its exact position.

Before attaching the cross-arms to the poles, spaces are cut for their reception—these spaces are technically called "*gains.*"

They are cut of sufficient width to give a snug fit to the side of the cross-arm and may be nearly two inches deep from the front of the pole. Brackets and cross-arms should always if possible, be attached before the pole is set ; and may be fastened with bolts and nuts, with or without the addition of lag screws or spikes. All screws, spikes or bolts used for this purpose *should be greased before they are used, to prevent rust.* Cross-arms should also be well painted before being attached to the pole.

It is a saving of both time and work to fit the cross-arm with its pins, and to screw on the insulators, before the pole is set up, yet the insulator should not be screwed down tight, but merely attached loosely; so that it can be screwed down when the wire is strung.

HOUSETOP LINES.

It should be a rule of the line constructor, never to run a housetop line if pole rights can be procured. A line run over housetops is absolutely at the mercy of the householder ; is liable to be cut at any time ; is by no means so strong as a pole line, and at any time an order to remove the fixtures may be expected.

Many telephone companies which built expensive housetop systems of lines when beginning business, have been compelled to completely rebuild, after paying immense sums as damages for alleged roof injuries, and poles are in all cases to be preferred. Yet housetop construction, to a

Digitized by Google

greater or less degree, will probably be carried on for some years yet, and an article on construction would manifestly be incomplete without reference to it.

The fixtures employed to support roof lines, are of several kinds—but may, perhaps, be broadly divided into the two great classes, *i.e.*, wall and roof fixtures. Both classes, again, may be either double or single, according to the number of wires which are to be supported. Roof fixtures are those which are placed with their foot on the roof—they are fastened to the roof by iron angle plates, which are fixed by screws, and are furthermore firmly braced by iron rods, in the direction of the wires on both sides.

Wall fixtures are spiked to a piece of plank about five feet long, 10 inches wide and two thick; the said plank being first spiked to the wall itself with seven inch spikes. These uprights are, or should be, five inches square and 20 feet long, 15 feet of which are elevated above the wall, the remaining five stretching over the baseplank. Such an upright may reasonably carry three cross-arms; the bottom one being 54 inches long; the middle one 33 inches, and the top one 18 inches long. The same thickness of upright may be used for double fixtures, but the cross-arms for these are, of course, extended across and supported by both uprights, which are braced together by wooden

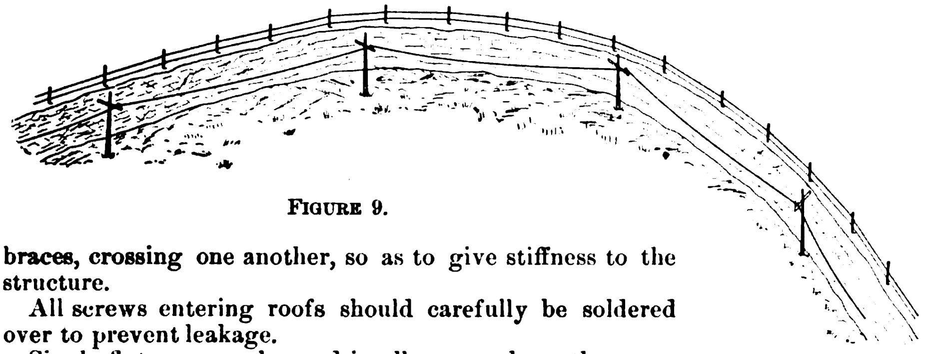

FIGURE 9.

braces, crossing one another, so as to give stiffness to the structure.

All screws entering roofs should carefully be soldered over to prevent leakage.

Single fixtures may be used in all cases where there are not more than a dozen wires. All housetop fixtures, cross-arms and boards ought to be of white pine, painted. In addition to these fixtures, some constructors use tripods, composed of three round iron rods welded together at the top, which is made to serve as the insulator pin. The use of these contrivances is not to be commended, unless they are made very high, inasmuch as wires run on them when low are apt to trip the unwary lineman precipitately into the street. Ridgepole irons and chimney irons are also sometimes used, and serve very well for the attachment of glass insulators, but on the whole, a wooden block, with a rubber-hook insulator is preferable for such work, especially if the wire is a light one, because in lieu of using a tie wire, the wire can be twisted round the hook, while where the block cannot be conveniently placed, a batten or counter-brace consisting of a three by four, or four by five-inch pine stick, spiked to the roof at one end, and projecting over, may be used. Without exception, housetop fixtures must be guyed against lateral strain.

Where a heavy line runs straight from fixture to fixture, it requires two guys to the fixture, one on each side, to stay it against the side pressure of the wind. When a line makes an angle with a fixture, the guy must be so arranged as to pull against the angular strain. Where the span on one side of a fixture is longer than that on the other, a guy is required on the short side to balance the surplus strain. It is customary to use No. 9 B. W. G. wire for housetop guys, although a pair of No. 12 wires will do quite as well.

ACTUAL CONSTRUCTION.

When a line, short or long, is to be built, unless the person in charge of the construction well knows the two terminal points, and all available routes between them, the road should be carefully gone over, and a route laid out, before any work is done, and if any rights of way are necessary, they should be arranged, so that when the construction gang comes along, it will have nothing to do but its own work. If it is a long line, and the men have to rest in a different place every night, suitable places should be agreed for, where they may board in as comfortable a manner as possible.

The person who goes over the road, if a capable and practical constructor himself, can render material assistance to those that follow after, besides aiding to soften the acerbities which sometimes spring up between the pole owners and the pole abutters, when passing through towns and villages. A line of wire has, of course, more or less, to follow the windings of the road, but in many places there is waste land, likely to remain so for years, and such places, when treeless, may be availed of to shorten the curves. Some suitable mark to designate where poles are to be planted is to be adopted, and while it is never well to be chary of poles where it is needful to set them pretty close together, it must not be forgotten that while multiplying the number of poles in a given distance does assuredly give greater mechanical permanence and stability to the line, it at the same depreciates the insulation by multiplying the possible points of leakage. Here, therefore, is a great chance for good judgment, and a good line is one in which the happy mean is taken.

It may be thought immaterial which side of the road is taken, but as a matter of fact this needs as much care as any part of the business. There are many points which may guide one in this matter, and frequently the conditions leave one without any alternative. The amount of adjoining waste land on either side, or the number of trees or houses, all aid in determining this question. All things being equal, however, on a curved road, it is far better to set the poles round the inside of the curve; and this for two reasons—in the first place the line is thus shortened; and in the second place—as may be seen by the diagram, figure 9, the line is thus arranged with the strain off the road, so that if the wire in any way becomes freed from one or more of the poles, it tends to swing away from, instead of over the road.

(*To be continued.*)

MEASURING THE VELOCITY OF PROJECTILES.[1]

BY HENRY A. SINCLAIR.

(Electrician U. S. Ordnance Proving Ground, Sandy Hook, N. J.)

I PROPOSE this evening to describe some of the instruments used for ascertaining the velocity of projectiles; but before doing so it might be well to state why it is desirable to know this velocity.

It is a means of comparing the powers of guns, of comparing different kinds of powders and projectiles, of determining their energy, and approximately their range and penetration into iron plates. When a new gun, a new kind of powder, or a new projectile is made, the question is not how far will it shoot; but what is its velocity and energy.

Very few persons realize how much energy a large projectile possesses. A 12-inch shot of 700 pounds, moving with a velocity of 1,500 feet per second, will have as much energy as a railroad train, consisting of a locomotive and five or six cars (weighing about 100 tons), moving at the

1. Read before the *New York Electrical Society*, February 25th, 1885.

Digitized by Google

rate of 57 miles per hour. The formula for energy being $E = \frac{W V^2}{2 g}$ in which W=weight, V= velocity, and g = force of gravity = 32.1651, we have for the projectile $\frac{700 \times 1500^2}{2 \times 32.1651 \times 2240} = 10,860 +$ foot tons. For the railroad train we have (100 tons = 224,000 pounds, 57 miles per hour = 83.6 feet per second) $E = \frac{224,000 \times 83.6^2}{2 \times 32.1651 \times 2,240}$ = 10,860 foot tons.

It thus being important to know the velocity, I will endeavor to show how it is determined, first mentioning some of the early attempts in this direction.

Robbins, as early as 1740, used the "ballistic pendulum," which consisted of a pendulum suspended from a tripod, the bob being so arranged as to receive the impact of the projectile, a prolongation of the pendulum below the bob registering its degree of vibration. In 1781, Count Rumford reported results of experiments made with the "gun pendulum," using a gun suspended in a horizontal position and free to vibrate. The arc of the recoil being accurately measured when the gun was fired. Extended experiments were made with this apparatus in this country between 1843 and 1848. Professor Wheatstone, in 1840, first suggested the use of electricity, which was tried as follows: Two targets of wire, so placed as to be cut by the projectile in flight, formed each a part of a circuit containing an electro-magnet. These magnets held each a pencil over a cylinder revolving uniformly, and as the targets were broken the pencils were released, dropped upon, and marked the cylinder. The speed of the cylinder being known, the distance between the two marks determined the time of the projectile's passage between the targets.

It will be seen that the use of electricity depends upon its great velocity which may be considered instantaneous for short distances, the difficulty being to register the exact instant the projectile ruptures the target wires.

Professor Henry, in 1843, proposed using the spark from an induction coil. This has since been used on some of the finest instruments. In 1849, Captain Navez used an instrument operated by an electro-magnet arresting the motion of a moving index. In 1854, Captain Siemens, of the Prussian service, used sparks from a Leyden jar.

Vignotti, in 1858, invented an instrument which consisted of a graduated arc holding a chemically prepared paper; a pendulum vibrating freely; and two induction coils, whose primary circuits were connected with the targets, and the secondary circuits connected in series, one pole to the pendulum, the other to the arc. An electro-magnet having in circuit a wire across the muzzle of the gun held the pendulum at its initial point and released it when the wire was broken. On breaking each target wire, a spark passed from the now falling pendulum to the arc, leaving impressions on the prepared paper. From the location of these impressions, the time of the projectile's passage between the targets was easily found and consequently its initial velocity. This instrument, with some modifications, was in use as late as 1876. Col. Benton's machine, invented in 1859, had two pendulums, their axes being in the same line, swinging freely in front of a graduated arc. Two electro-magnets so placed as to hold the pendulums in a horizontal position at opposite ends of the arc, are in the target circuits. The pendulums being released upon the breaking of the target wires mark the arc when passing each other, the position of this mark denoting the time of the projectile's flight. This machine is still occasionally used in this country.

Captain Schultz, of the French artillery, has devised an instrument by means of which intervals of time from 30 seconds to the $\frac{1}{5000}$ part of a second can be readily measured and even these may be subdivided. It consists essentially of a cylinder, an induction coil, a vibrating or tuning fork, electro-magnets, and a conjunctor. The cylinder, A, figure 1, is driven by a system of clock-work, operated by a weight, giving to it a double motion of rotation and translation, its bright surface (usually silver plated) being covered with a thin coating of lamp-black. At D is an induction coil, whose primary circuit is connected to the targets as follows: From one pole, E, wires lead to both the first and second targets, from the other pole, F, the

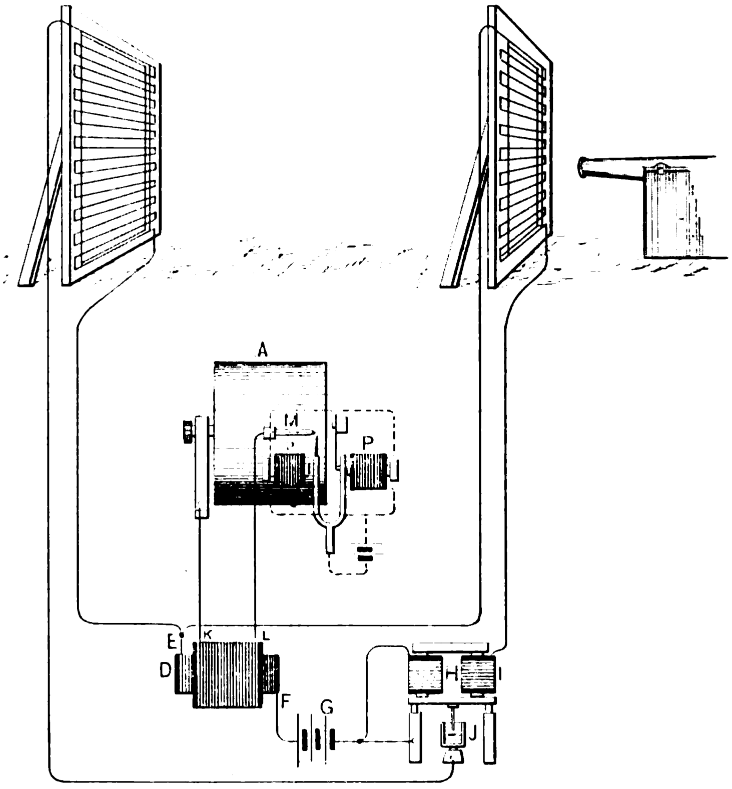

FIGURE 1.

circuit passes through the battery G, and the electro-magnet H, of the conjunctor I, to the other side of the first target. This electro-magnet holds an armature, carrying two metal rods, sliding in upright cylinders, also a small pin, the lower end being just above the surface of mercury contained in the cup J.

At the breaking of the first target wire, this armature is released completing the circuit through the mercury to the second target before the projectile reaches it. In the secondary coil, one pole, K, is connected to the frame work supporting the cylinder, and the other pole, L, passing through an insulating glass tube, M, terminates close to the surface of the cylinder, so that on the breaking of each target circuit a spark passes from the end of the wire to the cylinder, leaving a slight trace on its blackened surface.

Firmly secured to the bed plate of the instrument is a vibrating fork, the left prong of which carries a small quill which can be made to touch the cylinder at pleasure. On either side of the fork are electro-magnets, P P, which serve to originate and sustain its vibrations. From one pole of the battery the current enters at the bottom of the fork, passes up the right prong, and out at a light spring which just touches it, where it separates, half passing through each electro-magnet, and then, reuniting, passes to the other pole of the battery. When the circuit is closed the prongs are drawn apart by the magnets and the circuit at the spring is broken, the prongs being released return and close the circuit and again the magnets draw them apart. The fork is thus kept in constant vibration similarly to the fork in the Gray harmonic telegraph system. The quill on the other prong traces its vibrations on the blackened surface of the revolving cylinder. These vibrations are known to be isochronal for the same fork

Digitized by Google

when their amplitude is constant, that is, the fork makes the same number of to-and-fro motions in a second; thus giving a scale of time. On the breaking of each target circuit, the sparks fall in between or close to the line traced by the fork. We have then only to count the number of vibrations between the two sparks for the time.

The fork in use at Sandy Hook makes 250 double vibrations per second, consequently one vibration represents $\frac{1}{250}$ of a second. Suppose, for example, that the number of vibrations between the sparks is $16\frac{1}{4}$, the time will be $16\frac{1}{4} \div 250 = 0.065$ second and with a distance between targets of 100 feet, the velocity equals $100 \div 0.065 = 1423$ feet per second, or with the distance between the targets of 10 feet and the number of vibrations between the sparks 1.3, the velocity will be $10 \div \frac{1.3}{250} = 1993$ feet per second. When the cylinder is moving rapidly one vibration ($\frac{1}{250}$ of a second) covers about one inch space on its surface, this can be readily divided into 20 parts which would give $\frac{1}{5000}$ of a second, and by means of a micrometer even this is subdivided so as to read $\frac{1}{500000}$ of a second of time.

It will be seen that the speed of the cylinder does not

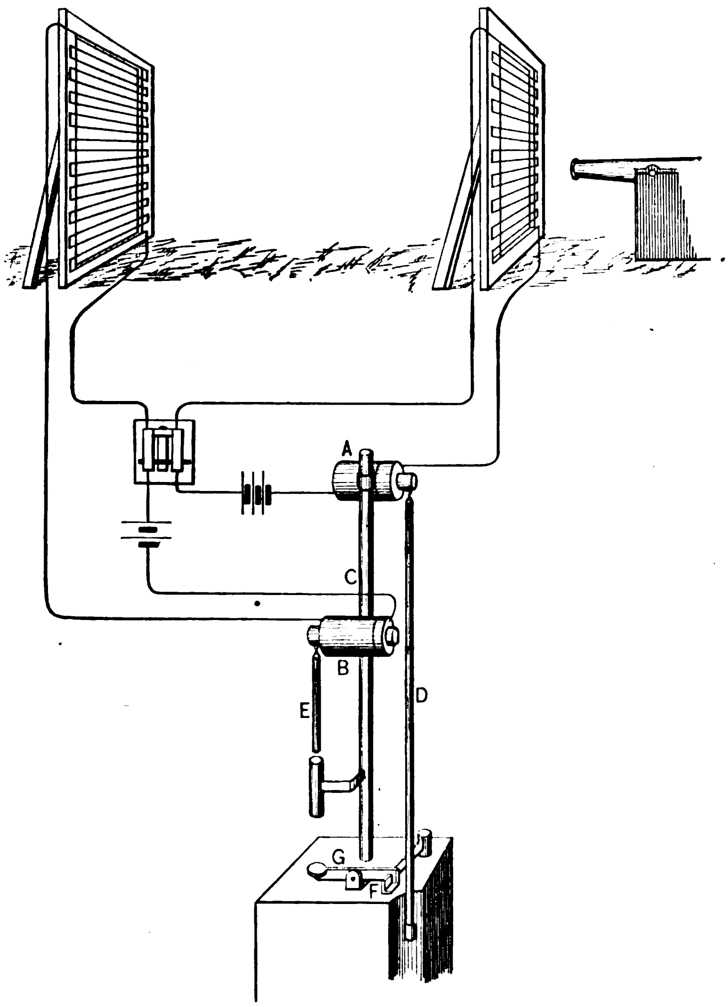

FIGURE 2.

affect the time—all that is necessary is that it should be uniform for one vibration. The targets are sometimes arranged with springs, so that the velocity is taken at 5 or 6 points or even more, the current being thrown from one target to the other in rapid succession.

The instrument now generally used both in this country and Europe is the "Boulengé chronograph," which for simplicity and ease of working is unexcelled. This instrument, figure 2, has two electro-magnets, A B, supported by the upright pillar, C. The upper magnet, A, is in the first target circuit, and suspends the long rod, D. The lower magnet, B, is in the second target circuit and holds the short rod, E. These rods are released on the breaking of their respective target circuits, the long rod falling in front of the circular cutter, F, secured to a stiff spring which is retained by the trigger or catch, G. The short rod being released at the breaking of the second target wires strikes the trigger and frees the cutter which darts out, making a small mark on the long rod as it is passing.

The height of this mark shows the distance the rod has fallen while the projectile is passing between the targets. The time is then calculated from the law of falling bodies $T=\sqrt{\frac{2H}{g}}$. It will be seen that there is a short interval of time lost while the rod E is falling and the long one is being marked. The amount of it is ascertained by breaking both wires at the same instant by means of a disjunctor shown at the left, when upon deducting this period from the total time, we have the *true time* of the projectile's flight.

Suppose the height of the mark made by the cutter on the long rod, by the breaking of both circuits at the same instant, with the disjunctor, is 0.36024 feet above the zero point, the time of fall will be $\sqrt{\frac{2\times0.36024}{32.1651}} = 0.149664$ of a second; and that the height obtained on the breaking of the target wires is 0.49410 feet, the total time of fall will be $\sqrt{\frac{2\times0.49410}{32.1651}} = 0.175279$ of a second, then we will have as the actual time of the projectile's flight $0.175279 - 0.149664 = 0.025615$ of a second, and taking the distance between the targets as four feet, the velocity will be $\frac{4}{0.025615} = 156$ feet per second; or supposing the disjunctor time is 0.150073 of a second and the total time of fall 0.169422, the velocity will be $\frac{4}{0.169422 - 0.150073} = 207$ feet per second.[2]

At Sandy Hook two instruments are used on independent circuits. The distance between the targets being 100 feet; the velocities are usually from three to six feet apart, though often the same.

The following results are taken from the records of the two instruments in use at that place:

Boulengé No. 17.	Boulengé No. 109.
645	644
959	956
1210	1206
1514	1514
1735	1735
1951	1953
2138	2132

The following are taken from the records of the Schultz and Boulengé at Watertown arsenal:

Schultz.	Boulengé.
1267	1271
1277	1275
1258	1258
1224	1225
1182	1182
1235	1240

These tables represent two velocities taken at each shot. The first, where two Boulengés were used, the second, a Boulengé and Schultz.

Mr. F. W. Cushing has lately invented an instrument which he describes as follows:

"A tuning fork is kept in vibration by means of electro-magnets and made to record each vibration upon chemically prepared paper. Across the contact points of the reed is thrown a shunt wire connected through the first 'frame,' while the main circuit passes through the second frame. On the projectile breaking the wire in first frame the vibrations of the reed begin to record themselves upon the paper and continue to do so until the projectile passes through the second frame, breaking the wire circuit. The time of

2. The above results were obtained in an experiment made at the meeting, using a 45-calibre revolver with a charge of 3—3½ grains powder, and a ball weighing 130 grains.

Digitized by Google

flight is ascertained by counting the dots upon the paper which indicate the number of fractions of a second that have been used up between the two breaks."

This is now being investigated by a government commission at Philadelphia.

In describing the instruments used for ascertaining the velocity of projectiles, I have not attempted to include all that are used for this purpose, but simply most of those that have been used and are now in general use in this country. It can be safely said that the "Boulengé chronograph" is steadily supplanting all others for ordinary use, where the necessary distance between targets can be obtained; and that instruments of the Schultz class are only used where it is desired to measure the velocity over very short distances, such as the gradually increasing velocity of a projectile along the bore of a gun.

An instrument employed in connection with the velocity instruments, is the "pressure gauge;" its object being to register the pressure in the bore at the time the gun is fired. It is shown in figure 3. In the steel housing, A, is a piston, B,

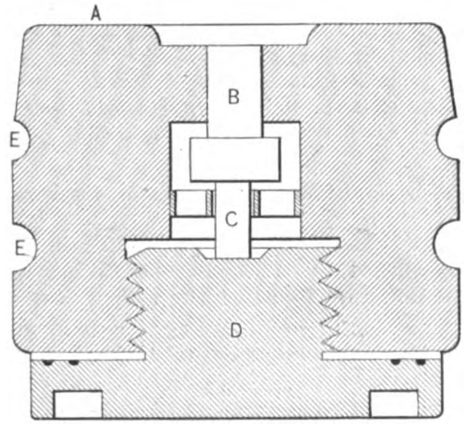

FIGURE 3.

resting on top of a small copper cylinder, C. The housing, A, has a screw plug, D, at the bottom, to admit the placing and removing of the copper cylinder as well as to form a base for it. The whole is tied to the bottom of the bag containing the powder and placed in the gun. On the firing of the gun the pressure of the powder gases forces the piston down, crushing the copper cylinder; the amount it is crushed depending upon the degree of pressure exerted. The length of the copper is then measured and the pressure required to reduce a similar copper to the same length is determined by a weighing machine. The area of the piston, B, being known, the pressure per square inch is easily found. An ordinary pressure for large cannon is from 25,000 to 35,000 pounds per square inch; but it often exceeds this, pressures having been recorded as high as 100,000 pounds per square inch.

By these instruments, the velocity instrument to determine the velocity, and the pressure gauge the pressure, we are enabled to ascertain what powder will give the maximum velocity and power with a minimum strain on the gun. Had this science been sufficiently advanced during the early part of the war, the commander of the Monitor could have used 30 or 40 pounds of powder instead of 15, and easily have sent his projectiles through the iron sides of the Merrimac.

ELECTRICAL MOTORS AND THEIR CONSTRUCTION.[1]

BY JOHN E. CHASTER.

(Continued from page 47).

THE machine is now ready for winding with wire. It must first be taken apart, and in doing this it is advisable to carefully number or otherwise mark the parts that fit together, so that no mistake may occur when the whole is finally put together. The portion of the field magnets with which the coils would otherwise touch must be carefully covered with cotton cloth or canvas, which must be well coated with shellac or Brunswick black varnish. In order to thoroughly insulate the wire from the body of the magnets, the field magnets are to be wrapped with six or seven layers of No. 18 (Birmingham gauge) double cotton covered wire. The proper amount of wire on the field magnets will be determined by there being just sufficient room for the armature to revolve when bolted up. About 1¼ pounds of wire will be ample for the field magnets, and seven or eight ounces of No. 22 (Birmingham gauge) double cotton covered for the armature. In winding the wire it is advisable to employ a Leclanché or other convenient battery, and a small detecting galvanometer or a vibrating bell, or even a telegraphic sounder, in circuit so that in case the insulated wire should at any point form a connection with the iron of the field magnets the fault will be detected. This may be effected by putting on the first convolution of wire and then joining the free end to one binding screw of the galvanometer or other detecting instrument From the other binding screw of the detector a wire is led to one terminal of the battery, the other terminal of the battery being placed in metallic contact with the iron of the field magnets. It will, therefore, be understood that if the wire that is being wrapped on the field magnets should in any place make metallic connection therewith the circuit will be closed and the galvanometer or other instrument will indicate the fact. Should this occur the wire must be unwound until the defect is discovered, when a piece of cotton, or better still, fine linen cloth must be wrapped around the bared place on the wire, before the latter is replaced.

Secure all the ends of the wires either to the neighboring coil or else by passing the finishing end beneath the adjoining layer and then drawing tight.[2] All the three, viz., the two field magnets and armature, are now ready to receive a coating on the insulated wire of thick shellac varnish. When dry, the machine may be finally mounted, and the ends of the field magnets so connected that the north pole of the one field magnet beds against the similar pole of the other field magnet.

When this has been ascertained, those two ends of wire should be cut short so that there is left just enough length to solder them together. This joint can then be insulated by binding round either cotton or tape, and carefully tucking same away so as to be out of sight as much as possible. One end of the field magnets is to be taken to one of the binding screws of the vulcanite (figure 22, page 47), and the other end goes to one of the brushes of the commutator. The other commutator brush has a short length of copper wire to the remaining binding screw. The machine is now ready for a test to ascertain how it runs. If carefully made, it will revolve with a single bichromate cell, though to get its full efficiency it will be necessary to employ six or eight bichromate cells, each cell having a zinc surface of 3½ in. wide and 6 inches long immersed in the liquid. With a small boxwood pulley on the shaft, and about ¾ in. to 1 inch in diameter and ½ in. in width, the machine is capable of driving a small lathe, fret-saw, or any light-running machinery.

Many persons have of late been writing against the Siemens H form of armature. For a dynamo from which a large amount of electrical energy is required, it certainly does heat after running a short time when made of large dimensions; but for small motors it is unquestionably the best, all things considered, and is by far the easiest for amateurs to fit together; and if made of the very best carburetted annealed iron, it does not heat to an extent sufficient to do any damage to the insulation of the wire.

(To be continued.)

1. *English Mechanic* (abridged).

2. It is hardly necessary to remark that the two ends of the armature coil should be brought out at the end of the armature, and carefully soldered to the inner ends of the two segments of the divided commutator. See fig. 18 p. 47 of this volume.—[EDITOR.]

INCANDESCENT LAMP ECONOMY.[1]

BY ASSISTANT ENGINEER W. D. WEAVER, U. S. N.

THE cost of a given light from an incandescent lamp depends upon three quantities: the cost of the lamp, its life, and the cost of the energy to produce the light, the latter value being the entire cost of the energy actually delivered at the lamp, depreciation of plant and interest on capital being taken into consideration. The relation between these quantities may be formulated as follows:

Let a = the entire cost of one h. p. per hour *at the lamp.*
b = cost of lamp.
l = life of lamp.
x = candle power.

Then $\frac{b}{lx}$ is the hourly *lamp* cost of one candle-power,

$\frac{CE}{745} \times a \times \frac{1}{x}$ is the hourly *energy* cost of the same,

and $\frac{b}{lx} + \frac{a\,CE}{745\,x}$ is the *entire* hourly cost of the unit of light.

If now the relation between the electrical energy transformed in a lamp and the resulting candle power were known, the economic conditions in respect to the life and cost of lamp and cost of h. p., could be determined by means of the above formula.

There is, however, a great diversity of opinion in regard to the law connecting these two variables. Dr. Higgs states that the candle-power varies as the fourth power of the current, or as the square of the energy; Dr. Hagen (Dresden) gives the powers as five and three, respectively, while Mr. Preece, in a paper read before the British Association at Montreal, gave the law that the candle-power varies as the sixth power of the current.

The plotted curve has evidently the form of curves represented by the equation $y = kx^n$, and its regularity suggests that the law is not so variable as to give reason for the diversity of values hitherto given, a conclusion justified by the result of the following investigation:

I.

In the calculations the data used were those of the careful experiments made at the Crystal Palace Electrical Exhibition, contained in an able report on the exhibition made to the navy department by Mr. F. J. Sprague, late U. S. N.

The values of n in the formula $y = kx^n$ were calculated for both energy and current by means of the following equations, in which P is the candle-power, C the current, and E the electro-motive force between the lamp terminals:

$$n' = \frac{\log. P_2 - \log. P_1}{\log. C_2 + \log. E_2 - \log. C_1 - \log. E_1}$$

$$n'' = \frac{\log. P_2 - \log. P_1}{\log. C_2 - \log. C_1}.$$

The data used were those from experiments on 18 lamps, —six Edison, six Swan, and six Maxim; the value of n was calculated for each successive experiment between about five candle-power and the highest power noted that gave satisfactory results, and also for the extreme values of the candle-power for each lamp.

The results are as given in the following table:

	Number of Determinations.	n' $(P = KCE^{n'})$	n'' $(P = KC^{n''})$
Mean for successive values of C. P.	51	2.72	4.64
Mean for extreme values of C. P.	18	2.71	4.70

Adopting as the exponent of the energy the value 2.70, the probable error with the above data is between + .07 and — .03. The variation of the value of the exponent of the current is much greater, however, and, adopting the value 4.70, the probable error is + .30.

It would appear that n has a slightly greater value for the large filament or Maxim lamp than for the lamps with finer filaments; thus, with the former the mean values of n' and n'' are 2.75 and 4.97 respectively, and the variation small; this difference may be owing, however, to the more satisfactory data of the Maxim lamp, due to its larger range of candle-power.

Although the above values of n are probably correct within the limits given, other determinations should be made with smaller increments of candle-power than in the experiments at the Crystal Palace, and the variation of the exponent n, if any, determined for different-sized filaments.

The following table will show the agreement of the calculated with the observed candle-power. The figures at the head of the columns are from the report on the Crystal Palace exhibition, and were taken by the committee from curves plotted with observed data. The other values were calculated from the equation $CE = KP^{\frac{1}{2.7}}$ in which k was determined for the normal candle-power.

Lamp.	Normal Candle-Power.	k.	Candle-Power. 5	10	15	20	30	60	90
Swan....	20	21.36	5.52	10.40	15.30	20	30.18	61.51	97.60
Maxim..	20	26.98	6.18	10.67	15.17	20	29.95	58.30	94.63
Edison...	16	30.26	5.92	10.42	15	19.7	30.24	62.37	102.6

From the data of experiments made at the Munich Exhibition on the Gatehouse lamp, the following table was calculated, using the formula $CE = KP^{\frac{1}{2.7}}$:

Observed C. P..	5.89	8.40	11.12	15.3	21.93	30.76	41.52
Calculated C. P.	6.87	9.01	11.67	15.3	20.3	27.3	38.3
Differences	.98	.61	.55	0	-19.3	-3.46	-3.12

As might have been expected from the difference of construction of the lamp, the agreement is not very close, and the differences show that the equation to the curve of this lamp is of a less degree, and by calculation from the data given was found to be $CE = KP^{\frac{1}{3}}$, and the constant k, 25.58.

II.

Knowing now the relation between the candle-power and energy, we will return to our first formula,

$$\frac{b}{lx} + \frac{a\,CE}{745\,x} \qquad (1)$$

Expressing the law just deduced in the same notation, and substituting for CE in (1), we have finally for the whole cost of the unit light

$$y = \frac{b}{lx} + \frac{akx^{\frac{1}{2.7}}}{745\,x} \qquad (2)$$

With this equation, some interesting problems in incandescent lighting may be solved, and from it the following tables were deduced, showing the economic relation between the life of a lamp, its cost, and the cost of the energy furnished it. Table I. was constructed by assuming the life of a normal 20-candle-power lamp to be 1,000 hours, and that the lamp *when working at its normal capacity* would produce the normal light at the rate of three watts per candle-power, the cost of the lamp being taken at $1.00, and the cost of an hourly h. p. at 1 cent; from

100	1	124	128	132	136	141	147	151
	2	141	151	163	178	195	218	240
	3	163	186	215	256	314	422	581

these data y was calculated and the life of the same lamp at other candle powers, and of other lamps of different efficiencies and at different candle powers was found, the cost of the unit light being the same in each case and as deduced from the above data. The watts at the head of the columns represent the efficiency of the lamp, and are the number of watts required to produce the unit light when the lamp is being used at its normal power—20-candle-power in each case; the figures 1, 2, 3 to the right of each candle-power are the respective costs of an hourly h. p., and enable a comparison to be made between the efficiencies at these different values, the cost of the unit light and of the lamp remaining the same. The other quantities are the lives that would have to be obtained in order that the cost of the unit light may remain the same as given for each table and therefore represent the relative efficiencies of different lamps at different candle powers and at the given constant cost of the unit of light. Table II. was calculated in the same manner, but assuming the cost, y, of the unit light to be that resulting when the energy costs two cents per hourly h. p., and in table III. the latter value is taken at three cents.

For any other cost b' of a lamp, the quantities in each table should be multiplied by the ratio $\frac{b'}{100}$.

If a relation could be established between different candle powers of a lamp and the resulting lives, by substitution in (2) and differentiation, the value of the candle-power could be obtained at which the cost of the unit light is a minimum. It is probable that an equation of the form $l = k(m - x)^n$ would approximately express this relation, m being the candle-power at which the filament is practically destroyed. As this important question from its commercial aspect appeals with especial force to those working large installations who have also the necessary facilities for making the experiments, it is probable that this final problem will soon be solved.

COMPARATIVE MEASUREMENTS OF THE ELECTRO-MAGNETIC ATTRACTION OF CYLINDRICAL AND BICONICAL CORES IN SOLENOIDS.

Mr. Krizik has stated it as a law that the force with which an iron bar is attracted into a helix is at its maximum when one end of the bar is at the longitudinal centre of the coil. Dr. E. Böttcher shows[1] that this law as a generalization is not correct and holds good only in special cases. The maximum of attraction and the corresponding position of the core in the solenoid, are dependent on the ratio of their respective lengths. If the core and the solenoid are of equal lengths, the maximum attraction takes place when the core is inserted three-quarters of its length within the solenoid. If the core is twice as long as the coil, the maximum attraction takes place when half the core is within the coil, and half without. If the core is three times the length of the coil, the point of maximum is when two-thirds of the core is out of the coil. These values hold good equally for cylindrical and biconical cores.

In Dr. Böttcher's opinion the biconical core possesses no advantage whatever over the cylindrical core, so that it is of no importance which is used in an arc lamp,—at all events in the case of a single lamp; and it is due to the differential arrangement of coils, originally introduced by Von Hefner Alteneck, that a longer core can be used for regulation of the arc.

For determining of the attraction exerted by a coil on an iron core in different positions, Dr. Böttcher made use of a Salter's spring-balance, from which was suspended an iron core 1 cm. in diameter and 20 cm. long. A solenoid, also 20 cm. long, was connected in circuit with a Schuckert dynamo, and was placed in various positions in respect to the core, both above and below it, but so as always to surround it. The following table gives the results where the figures are the weight in grammes corresponding to the attractive force exerted :

Length of core outside coil.	Strength of magnetizing current in ampères.		
	4	5	6
Cm.	Grammes.	Grammes.	Grammes.
15	6.5	10	14
10	13.0	18	27
5	14.5	20	30
1	6.5	10	14

The relation between attraction and the length of core is, perhaps, better shown in the following curves plotted from the above values—the abscissæ represent the length in cm. of the portion of the core projecting beyond the coil, while the ordinates measure the weight in grammes corresponding to the attractive force (see figure 1).

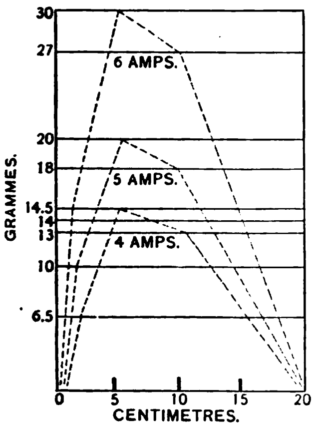

Figure 1.

He subsequently made some further experiments, from which the curves figures 2 and 3 are selected. These show clearly that there is no difference in the behavior of conical or cylindrical cores under similar conditions.

Dr. Dietrich, commenting upon the above results obtained by Dr. Böttcher, proposes the following inquiries :[2]

1. With reference to efficient regulation, what form of core is best for single lamps with one coil in the main circuit?

2. What result will be obtained, if in lamps with differential regulating coils the cylindrical core is replaced by a biconical one?

In discussing these questions, Dr. Dietrich considers only those lamps having no clamping mechanism, so that the core has a very long travel as the carbons burn away, and for a single lamp he takes as an example, Jaspar's. In this case we have in one direction the attractive force of the coil, and on the other an opposing force made up of the weight of the carbon, carbon - holder, core, etc. Both the attractive and the antagonistic force may be regarded as functions of the distance intervening between the centre of the core and the centre of the coil, and may be plotted on a system of rectangular co-ordinates.

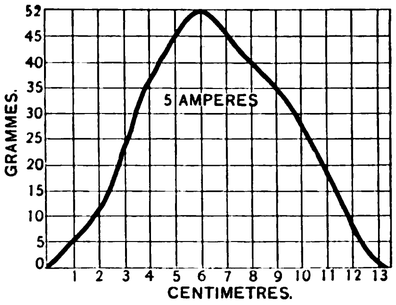

Figure 2.

If now a single lamp with one coil in the main circuit is to work properly, it must regulate for the same current at every position of the carbons; for only on this condition (the external circumstances remaining unaltered), can the length of the arc be made to remain constant from beginning to end of the burning. Hence in each and every position of the core, the attraction corresponding to the normal current must be equal to the antagonistic force, or, in other words, the curves of the attractive and of the antagonistic force must be identical. If this is not the case, then for different positions of the core equilibrium is only possible for different strengths of current, as is shown in figure 4, in which the curves J, J[1], J[2], represent the varying attractive power of the coil for varying currents, while the opposing force is represented by a single curve, since it remains constant. The abscissæ correspond to the distance from centre of core to centre of coil; and equilibrium can only occur at those points where the curve of attraction cuts the other curves. Hence the length of the arc will change as the carbons burn away and the core descends in the coil.

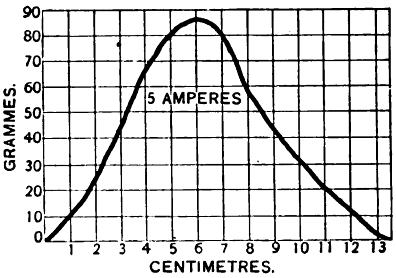

Figure 3.

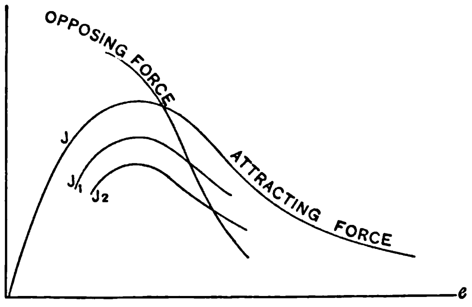

Figure 4.

The author arrives at the conclusion, in answer to his first question, that either a cylindrical or biconical core is equally efficient.

Upon consideration of the second question, it is clear that the curve of the attraction of the main coil corresponding to the normal current and the curve of attraction of the shunt-coil for a constant current in the shunt must also coincide. Now with cylindrical cores these two curves

1. *Centralblatt fur Elektrotechnik*, vi., 324.
2. Ibid. vi., 485.

Digitized by Google

do not coincide, for the curve of the shunt coil forms an asymptote just at that point where the curve of the main coils falls suddenly, and *vice versa*. Accordingly, in order to equalize the two magnetic forces, either a mechanical force must be introduced, as for instance, by means of an eccentric wheel, or the cylindrical core must be replaced by one whose curve of attraction falls more quickly; and this is found to be the case with a biconical core.

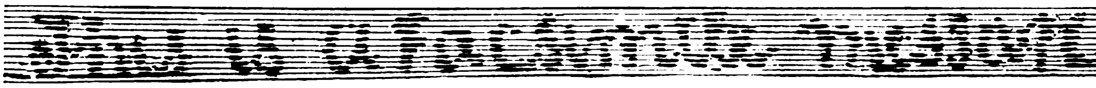
To sum up, then, for single lamps with one coil only, either form of core may be used; for several lamps in circuit with two coils in each, without a clamping device, the biconical form is preferable.

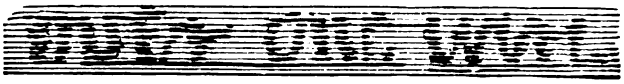
DELANY'S FAC-SIMILE TELEGRAPHIC TRANSMISSION.[1]

BY PROF. EDWIN J. HOUSTON.

It will doubtless interest the readers of the *Journal* to learn that Mr. P. B. Delany, the inventor of the first successful synchronous-multiplex telegraphic system, has fulfilled the promise he made a long time ago, and has practically applied his invention to fac-simile transmission, whereby the hand-writing of a correspondent, pen sketches, maps, plans, hieroglyphics, etc., can be sent over a telegraph wire and reproduced at the receiving station with all their distinctive characteristics.

I have had occasion, in previous articles on the synchronous-multiplex system, to call attention to the fact that the synchronous division of an ordinary telegraph wire into a number of parts, would eventually be applied to the transmission of fac-simile despatches. I have to-day received from Mr. Delany copies of the first fac-simile transmission with a crude experimental apparatus, which are herewith reproduced.





Although other systems of fac-simile transmission have been tried, and fac-simile despatches have been sent and successfully reproduced, yet when but a single wire was employed, the time required for the transmission was so protracted, and the uncertainty of correct reproduction so great, that such systems of transmission could never come into actual commercial use.

Mr. Delany's system, however, differs from the preceding in that it insures speed and certainty of correct reproduction. By means of the application of his synchronous system an area of 12 square inches can be covered in one minute by the use of a single wire.

The many uses of this system of fac-simile transmission can scarcely be properly appreciated at this time; for, notwithstanding the comparatively coarse lines that are so evident in the specimens annexed, yet with more carefully prepared apparatus, constructed for actual use, we do not doubt but that Mr. Delany will be able to transmit portraits, and other similar work equal in fineness to the ordinary wood-cut, so that criminals may be readily intercepted in their flight by the telegraphing of their portraits; or, in times of war, maps showing the movements of armies, sketches of fortifications and works may be transmitted; or the illustrated papers may be furnished, telegraphically with sketches of disasters, at the same time that particulars of the same are being transmitted to them.

An evident advantage of such a system of telegraphic transmission is in the readiness with which it can telegraph in any language, even Chinese, for instance.

DYNAMO-ELECTROTYPING AT THE ORDNANCE SURVEY OFFICE.[1]

At the last meeting of the Society of Telegraph Engineers and Electricians a most interesting paper was read by Captain H. R. Sankey, R. E., on some experiments in electrotyping with a dynamo-electric machine, carried out at the Ordnance Survey Office, Southampton.

Electrotyping has been in use for the past thirty-seven years in the Ordnance Survey, in order to produce the copper clichés or plates from which the plans are printed. The original plates on which the survey is first engraved are thus preserved intact without being printed from. Inasmuch, however, as corrections and additions, such as new railways, are made on the electrotyped copy, the deposited copper of which it consists must allow of being engraved; and hence it is important to deposit a copper of uniform texture and without grit.

The practice of "backing" the electrotypes has not been adopted in the Survey. The matrices are made $\frac{1}{16}$ in. thick and the duplicates $\frac{1}{8}$ in. thick; the latter being of uniform thickness throughout in order to pass through the press.

In the older process the current for each depositing bath is supplied by one very large Smee cell. The results obtained by this method were excellent; but the process was expensive, and for this and other practical reasons, Captain Sankey undertook experiments with the dynamo-electric current. The average size of the plate to be deposited upon is 7 square feet; and to keep the deposit uniform the receiving plate or cathode is placed *below* the dissolving plate or anode, as the reverse arrangement is not found to

1. *Engineering.*

Digitized by Google

answer well. The solution is kept in motion by gently rocking the baths.

In August, 1882, Mr. Elmore made some experiments with a dynamo in this direction, but the copper deposited was useless for the purposes of the Survey, as it could not be engraved upon.

These experiments were completed in July, 1883, and in January, 1884, Captain Sankey was instructed by the Director of the Survey to continue the experiments. His endeavor was to avoid working by mere "rule of thumb" in order to arrive at the best solution of the problem, which presented several new features. For the requirements of the Survey it was necessary that:

1. The density of the current should lie within certain limits.

2. The current should be kept constant during the deposition.

In order to satisfy the first requirement, he decided upon using a current of 30 ampères, because the current used in the existing arrangement as measured by Cardew's ammeter, was found to be from 23.4 to 26.4 ampères in different baths. Furthermore, 1½ lb. of copper per bath was found to be deposited in twenty-four hours, which corresponds to a current of 24 ampères.

To obtain a steady current from the dynamo during deposition, a high-speed engine and an electrical governor were requisite; and Captain Sankey, after careful consideration, selected a Willans six-cylinder compound engine and a Willans electrical governor. Both of these machines are found to answer admirably; the governor is extremely sensitive, and does not "hunt." It is in fact "dead-beat."

The question as to how the baths should be arranged had next to be settled; whether they should be placed "in parallel" or "in series" or in "combined parallel and series." The "parallel" arrangement was found unsuitable for the purpose owing to the difficulty of regulating the current. The combined arrangement was open to the same objection, and the series was found to be preferable to either, since one regulation of the current was sufficient. As Captain Sankey remarks, however, it does not follow that the series arrangement is preferable in all cases of deposition. For his purpose it was found the best.

The Elmore dynamo employed was originally arranged for working in parallel, by the coils being placed in parallel, but on placing them in series, or combined parallel and series, the electromotive force, it was thought, might be adjusted, and this proved to be the fact.

To find the electromotive force required the resistance of the baths was measured with a slide-resistance Wheatstone balance, and found to be 0.0087 ohm on an average. A reflector was used, and a commutor to overcome polarization. This bridge can measure 0.001 ohm to $\frac{1}{200,000}$ ohm.

The counter electromotive force was compared by the deflection method and a reflecting galvanometer with that of a Daniell cell and found to be 0.005 to 0.016 volt. Hence the electromotive force required per bath,

$$30 \text{ amp.} \times 0.0087 \text{ volt} + .016 \text{ volt} = 0.276 \text{ volt.}$$

This, therefore, was the electromotive force required at the terminals of the bath.

With regard to the number of baths, the output was to be 120 lb. per week; the dynamo had to work 44 hours; hence by a formula given by Captain Sankey,

$$x \times \frac{30 \text{ amp.} \times 44 \text{ hours}}{384} = 120 \text{ lb.}$$

where $x = 35$, the number of baths required. The total electromotive force required for the series of baths was therefore

$$35 \times 0.276 = 9.7 \text{ volts, or say, 10 volts.}$$

The dynamo was then tried and altered by Captain Sankey until it gave 10 volts and 30 ampères. The field magnets were placed in a shunt with the circuit; a coiled iron wire resistance being added to the field circuit by means of which the current could be kept constant, and also the speed, approximately, whilst the resistance, or in other words the number of baths in circuit was altered.

In these trials the current was measured by Cardew's ammeter, and the electromotive force by Poggendorff's method, using two Daniell cells with two porous pots and zinc cylinders between the pots to precipitate any copper finding its way through the first porous pot. The resistance was measured by the post-office pattern of Wheatstone's bridge. The following table gives the results of these tests.

EXPERIMENTS WITH ELMORE DYNAMO.

Armature.—Diameter, 1 ft. 6¼ in. Arranged in two sets of ten coils in series, the two sets being in parallel. Resistance cold, 0.0297 ohm.

Fields.—Twenty coils arranged in series. Resistance cold, 0.684 ohm. Placed in shunt with circuit.

REMARKS.—The engine was worked compound for all experiments, except No. 33, when it was worked simple. An additional resistance of 0.85 was placed in field magnet circuit.

The solenoid of Willans's governor was then wound to take 30 ampères, and placed in series with one experimental bath, and a resistance equivalent to the rest. A Cardew's ammeter was placed in circuit to measure the current at intervals, and the governor was found to keep the current quite constant. The first plate was kept in the bath 31¾ hours, and the deposit weighed 1076 grammes of excellent copper. The corresponding current to this is 28.7 ampères; Cardew's ammeter showed 29.2 ampères. Captain Sankey, thinking this copper finer than that deposited by the Smee cell, tried the effect of increasing the density of the current by diminishing the size of the receiving plate gradually. The governor was adjusted to 30.5 ampères.

Digitized by Google

The following results were obtained:

Current through Bath.	Size of Plate.	Density of Current.	Current for a Plate 2 ft. 4 in. by 3 ft. 4 in.	Quality of Copper.
	sq. ft.			
30.5	5.	6.1	47.0	good
30.5	4.	7.6	58.5	"
30.5	2.8	10.0	77.0	good; but rather rough at edges.

It therefore appeared that the current might be increased to 50 ampères.

At the same time that the above plates were being deposited upon, a matrix was laid down with the intention of producing a duplicate of the full thickness (⅛ in.); but this intention was given up, as it was found that without doubt the copper deposited by the dynamo was as good for the purpose of the Survey as that deposited by the Smee cell.

The experiments were thus brought to a successful close, and the fittings of the Survey Office at Southampton are now being altered for the removal of the Smee cells. The experiments on plates of 5, 4, and 2.8 square feet in area were made in a vertical bath. The solution being allowed to remain undisturbed at first, it became weak at the top and the resistance increased, but the current, however, remained constant until the throttle valve was fully open. Air was now blown in, rising from the bottom of the bath in large bubbles, and soon equalized the solution. Captain Sankey therefore hopes that vertical baths may be used for matrices; but they are unsuitable for duplicates because the deposit becomes thicker at the bottom. The arrangement of the baths is a very important step in Captain Sankey's experiments, and it will facilitate the use of dynamos for electrotyping, since it will allow of the employment of machines giving a considerable electromotive force and current, without having recourse to dynamos of expensive and special construction. The arrangement in series, as Captain Sankey pointed out, was adopted because it was found the best for the purpose in view, which was to deposit copper of a certain quality, not to deposit it in large quantities.

In the discussion which followed Captain Sankey's paper, Mr. Spagnoletti, Professor Forbes, and Mr. Crompton took part, the latter observing that the results there given were just those which dynamo makers required, and had not been able to obtain. Mr. Gisbert Kapp alluded to some experiments in which he had found the counter-electromotive force to be 0.7 to 0.9 volt. Professor Ayrton thought the counter-electromotive force could not be so high as that, and stated that Mr. Sprague (in Munro and Jamieson's electrical pocket-book) had given it as 0.02, or nearly the same as 0.016, which had been found by Captain Sankey.

Captain Sankey illustrated his paper by a number of excellent samples of copper deposited by dynamo currents of densities ranging from 3.6 to 10 ampères per square foot; and also some deposited by Smee cells, including a matrix of part of the map of London, and a plate deposited by a current too strong and showing signs of granular structure. Samples of copper deposited by Mr. Elmore with a dynamo were likewise exhibited. A proof sheet of the Isle of Wight, in four sheets recently joined together, was exhibited to show that the deposited copper must be capable of being engraved. The matrices of the four sheets were cut and joined by soldering and riveting, then a duplicate deposited. The plate has to be engraved along the junctions. The Daniell cells and Willans governor employed in the experiments were also exhibited to the meeting.

THE ELECTRIC LIGHT ON THE BRIGHTON RAILWAY.[1]

BY W. SLINGO.

Amidst the many inconveniences that await the average railway traveler, there is, to my mind, not one that is more trying or vexatious than to be compelled to sit out a long journey in a carriage illuminated (!) by the old, dirty, smoky oil lamp. Nevertheless, until very recently, this is what one and all had to do whose business or pleasure involved them in a railway journey at a time when sunlight was absent; and even now we are oftener than not compelled to undergo the same torment.

The introduction of the Pintsch gas system wrought a revolution on a small scale. Our underground railway trains are fitted under it, and it has found support in a few other directions. But the greatest result, perhaps, which has been brought about by even a limited application of the system is that it has shown the public that a light superior to that given by oil is practicable; and, were nothing else available, the railway companies would, sooner or later, be compelled by force of public opinion to adopt it.

There is, however, something which is superior to gas even in a railway carriage, and that something is electricity. We certainly owe it to the eminently able and enterprising management of the London, Brighton, and South Coast railway that electricity, as an illuminating agent in railway carriages, has been proved; for the first experiments in this direction were made by that company some three years ago, when the Pullman express, which runs daily between the Victoria and Brighton stations, was lighted by electricity. In that case accumulators of the Faure type—some of the very first brought into England—were employed.

They were charged overnight at Victoria by means of a dynamo worked by a gas-engine (wires being led from the shed to the brake-van), and supplied throughout the day sufficient current to illuminate the 28 lamps fitted in the various carriages composing the train, which performed the journey from London to Brighton and back twice daily.

The advantages of the system over the previously employed oil lamps were, it is almost needless to say, too real and too apparent not to secure at once the admiration and gratification of the patrons of the line. The light was steady, clear, and only showed itself when wanted.

Illumination by oil or gas means that in the day-time, if the train has to run a 50 mile or even longer journey, and has one or two short tunnels to traverse, the lamps must all be burning through the entire length of the journey on account of the tunnels.

With the electric light this is not the case. The guard is provided with a simple switch, by turning which he is able to send the current into the lamps on approaching a tunnel, and to stop the current on emerging from the tunnel. Here, then, is a very decided advantage in favor of electricity.

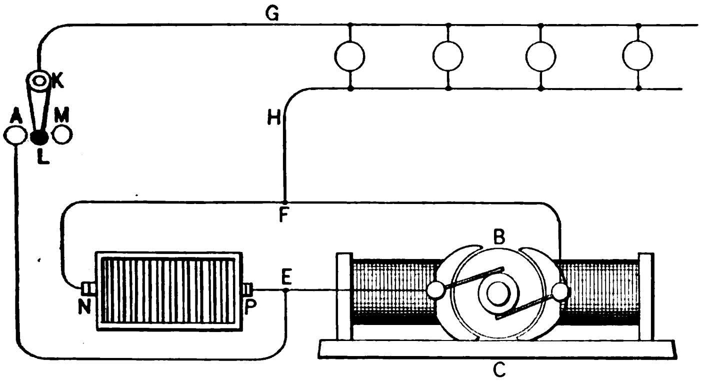
The train thus fitted has continued its daily journeys since the inauguration of the system, but there were soon discovered many features in connection with it that required modification before it could become the commercial success that was hoped for it. In the first place, there was the expense of the gas engine and its attendant. This is a serious objection, to say nothing of the allowance that ought to be made for renting the engine house. It may, however, be observed that, were the system extended to several trains instead of a single one, so as to divide the engine and accessory expenses between them, the cost per train would obviously be considerably reduced.

In the following year a new system was introduced, and employed on the London-bridge and Brighton express, and on a local train running between Victoria, Crystal Palace,

1. *Knowledge.*

Digitized by Google

and London-bridge, &c. It had been worked out by Mr. Stroudley, the talented engineer to the company, and Mr. Houghton, its energetic telegraph superintendent. In this system the engine was discarded entirely, and the dynamo was fixed in the brake-van, and worked from a countershaft geared on to one of the axles. While the train travels at a sufficiently rapid rate, it is easy to see that the dynamo might be driven fast enough to feed the lamps. But whence is the electricity to come necessary to illuminate the lamps when the train is traveling slowly or when it is standing still? This is accomplished in a very simple



Train Lighting System.

manner. While the train is running rapidly, electricity may be generated, whether the light is wanted or not. Consequently, the dynamo, B C, is permanently connected to a set of 20 accumulators, N P. Other wires, however, are connected at E F to the wires joining the dynamo to the accumulators, and these other wires are connected to the lamps in the various parts of the train. It follows that, were there no electrical energy stored in the accumulators, the current from the dynamo would divide between them and the lamps. The accumulators are never wholly discharged, however; but, even were they so, sufficient charge would soon accumulate to prevent this division, for it must be remembered that electricity, in charging accumulators, sets up a "counter electro-motive force," and if this force is equal to that of the generator no electricity will flow into it, although a very small difference is sufficient to maintain a current. Moreover, when the lamps and accumulators are all in circuit, but little electricity will flow into the latter, because the "difference of potential" between the dynamo and lamps is equal to that between the brushes of the dynamo itself, while the "difference of potential" between the dynamo and accumulators is only a fraction of that amount; and, as the greater proportion of electricity flows between point of greater difference of potential, nearly the whole current produced will be absorbed by the lamps.

A switch is provided in the lamp circuit, so that the guard may be able to disconnect it when the light is not required. The current will then be utilized by the accumulators. In the diagram, K L is the handle of the switch hinged at K. When L is over A, the lamps are disconnected, but when it is over M, they are in circuit.

One great feature of the Stroudley-Houghton system is the automatic controlling apparatus. This originally took the form of a governor, which was fitted in November, 1883; but in August, 1884, the work in the local train was transferred to a mercury pump. This consisted of two vertical tubes, the lower ends of which opened into a cylinder. In this a coarse-threaded screw was made to revolve by being connected to a small pulley-wheel, over which passed a strap, which also passed round the spindle of the dynamo. When the train was in motion the pulley-wheel revolved, and with it the screw in the cylinder. The cylinder and lower portions of the tubes being filled with mercury, the revolution of the screw caused the mercury to fall in one tube and rise in the other. At a certain height in each tube, above the normal level of the mercury, was an adjustable contact point, and the mercury, on reaching one or the other, completed the dynamo's exciting circuit. When the train traveled in one direction, the pulley-wheel traveling with it would bring about the rise of the mercury in one tube; when it traveled in the opposite direction the mercury would rise in the other tube. The "shunt" circuit thus closed, in turn joined up the main circuit automatically.

There was another and most important function pertaining to the mercury pump. The electromotive force produced in the coils of a dynamo varies with the speed at which the armature rotates. Accordingly, when running slowly (or not running at all), the accumulators would have a higher electromotive force than the dynamo, and if the circuit between them were complete, the former would discharge themselves through the coils of the machine. The mercury pump, however, prevents this. The gearing which drives the screw is so arranged that the mercury is made to rise in one of the tubes only when a speed of 12 miles an hour is attained. At that speed the dynamo runs fast enough to produce the necessary electromotive force.

The dynamo originally used was one of Messrs. Siemens' machines (type D 2). After some months, this was superseded by a Brush machine, provided with a Schuckert armature; but any dynamo having the necessary electromotive force can be employed, and it is now proposed to use dynamos which are free from the chief disadvantage of a Brush machine—viz., that it will not respond to demands for an increase of current in emergencies. The current produced is one of 56 ampères, with an electromotive force of 45 volts. A double set of "brushes" is provided, in consequence of the frequent change in the direction in which the armature rotates, and they are so fitted as to work automatically.

The 32 accumulators originally fitted were of the first type of Faure cell, which did not answer so well as was hoped, but those now employed give every satisfaction, test well, and have been in daily use in the Pullman limited express since December, 1882, showing a result in every way satisfactory. There is this to be said, that the vibration of the train may be calculated to do them more good than harm.

There are in the express train 56, and in the local train 36 Woodhouse and Rawson incandescent lamps, each taking about 1·15 ampères, with an electromotive force of 40 volts. Other lamps have been tried, but Mr. Houghton's experience is that their carbon filaments are too fragile to withstand the vibration of the train, while the lamps now in use have answered every requirement for the past 11 months.

A train fitted up on the Stroudley-Houghton system has lately started running on the South-Eastern railway, between London and Maidstone.

The weight of the accumulators is about 22 cwt., and of the dynamo eight cwt., making in all 30 cwt.

The local train, which offers certainly the severest test, has been running continuously for 14 months, making about 3,200 trips, and running about 40,000 miles, giving during that time every satisfaction. The trains have been equipped by the Railway Electrical Contractors (Limited), 4 Great Winchester Street, E.C., and the result speaks well for the managing director, Mr. T. M. Collet.

With reference to the relative cost of the system, complete details cannot be given. The cost of the oil previously consumed and wasted is saved, and this is a considerable item. There is no cost for lamp cleaners, as the lamps require no cleaning. The energy absorbed by the lamps is but three electrical h. p.; and, making the widest allowance for waste in the dynamo and bearings, the additional consumption of coal in the engine is small. As a matter of fact, the driver is unable to detect any difference in the consumption; and many a time has it happened that

Digitized by Google

the driver has not been aware of the fact that he is lighting the train as well as drawing it, until he has arrived at the end of his journey. Practically, then, the cost of the light is almost reducible to depreciation of stock (wearing out of dynamo and accumulators, breakage of lamps, &c.) and interest on capital outlay. Labor costs but a tithe of that which is necessary for oil lamps, all that is required being occasional inspection and lubrication.

It is earnestly to be hoped that the success of the enterprise will increase, and prove in every sense of the word satisfactory; and that the day may not be long in coming when we shall regard oil lamps as another relic of the "good old times."

THE ELECTRICAL TRANSMISSION OF POWER IN MINES.[1]

In his work on this subject, Professor W. S. Schulz furnishes several interesting tables; one of them gives the results of electrical transmission already realized in the mines:

Name of mine.	Power of the moto[r] in h. p.	Machine actuated.	Length of conductors. Mètres.	Per cent. of efficiency. Electrical.	Mechanical.	Total.
La Perronière, near Rive-de-Gier	37.1	Traction machine.	1,500	50	37	30
Thibaut, near St. Etienne	5.0	" "	250	45	38	25
Blanzy	17.0	" "	634		51	30
Zankeroda	14.7	Locomotive.	893	46.6	37.8	30
"	5.0	Ventilator.	780	50.	.26.	
St. Claude, near Blanzy	8.1	"	900			

Taking these results as a basis, the author compares the cost of the electrical transmission of force, with that of the transmission by means of compressed air and of water applied to drills and to machines for the extraction of coal by means of locomotives, of hoisting machines and by means of ventilators. He finds thus that the first method is more costly than any of the others, except that which employs air compressed by steam without cooling, as well as locomotives for towing on a level. The following table gives the comparative costs of a system of transportation of this kind, in operation:

SUBTERRANEAN TRANSPORTATION BY LOCOMOTIVES.

	Steam.		Compressed air.		Electricity.
	Dornan mine.	Cesson mine.	Petan system.	Mékarski system.	Zankeroda mine.
First cost of installation (francs)	40,000	40,000	16,250	25,000	20,000
Interest, etc., per ton-kilomètre (centimes)	2.64	0.9	4.90	5.02	2.76
Cost of transportation (centimes)	3.72	3.16	7.36	8.41	6.80
Total cost (centimes)	6.36	4.07	12.26	13.43	9.56
Daily work (tons-kilomètres)	488	1,421	106	159	235
Length of line (mètres)	2,320	4,627	620	620	620
Speed	2.3	3.3	1.5	1.5	2.6
Weight of machine (kilogrammes)	4,400	8,000	2,700	2,300	1,600
Height (mètres)	1.92	2.1		1.55	1.5
Width (mètres)	1.30	1.6		1.10	0.8

For the separate ventilation of a lateral cutting in the Zankeroda mine, there is employed a Schiele ventilator of 40 inches, fed by a Siemens dynamo driven by a Dolgorouki steam engine; the cost is 2.0 centimes per 1,000 cubic mètres, which is a better return than from the transmission of compressed air, except when it is necessary to make a special installation for compression for the small ventilator. The author concludes that mines do not offer a promising field for the electrical transmission of force, outside of some isolated cases, and except for transportation by locomotives on level ground, where it may advantageously replace traction by rope or cable.

1. *La Lumiere Electrique*, xv., 91.

PROGRESS OF THE ELECTRIC RAILWAY.

We note that electric railways are making steady progress in Great Britain. The line at Portrush (Ireland) has now been opened a year, and has proved so great an attraction that the number of visitors to the Giant's Causeway has been increased tenfold. The line runs through very pretty coast scenery, but is a difficult one to work, being a succession of heavy gradients and sharp curves, with practically no level ground for the whole six miles. The turbines answer admirably as the source of power; and the River Rush never fails in the dryest season. At Newry, a town midway between Belfast and Dublin, another electric railway is being constructed by the Bessbrook Spinning Company, the length of which will be about three miles. Two gangs of men are busily engaged in grading and bridging, and the rails have been laid for a considerable distance. As soon as the track is completed Dr. Hopkinson, for the firm of Siemens Brothers, London, will commence the work of erecting the electrical machinery, which will be placed in an old flour mill situated in Millwall, about midway between Bessbrook and Newry. The opening ceremony is expected to take place early in the year. Active preparations are also being made to open a system of electrical tramways at Blackpool, which, in anticipation at least, are to surpass everything hitherto attempted; and it is hoped that the work will be completed early in the spring. A deputation of the local authorities of Blackpool recently visited the Brighton electric railway. For electric railways at the Novelties Exhibition next year no less than three distinct applications to exhibit have been made; but the limited space available will doubtless prevent their being granted. The Brighton electric railway, during the height of the fashionable season, was crowded for several hours daily, and arrangements are being made to run extra cars, passing on a loop half-way along the line.

THE UNIT OF LIGHT.

The English standard candle and the French carcel are both unsatisfactory and unreliable, and many attempts have been made to substitute for them a more perfect standard of reference. The proposal to employ a square centimetre of platinum at the point of fusion, recommended a few months ago at Paris, is too impracticable and uncertain for general adoption, but this objection does not apply to the unit proposed by Dr. Siemens, and discovered by Hefner-Alteneck. This standard is the light given by burning acetate of amyl in an open burner at such a rate that after ten minutes the dimensions of the flame are, diameter $\frac{5}{16}$in.; length, 2.6in. This fluid boils at 138.6° C., and is inexplosive and therefore perfectly safe. There are various other similar substances that may be employed with equal accuracy, and they all appear to possess the advantage that they may be burnt with a hard or soft spun wick which may be accurately or carelessly trimmed. These substances are the valerianates, acetates or formiates of amyl, isobutyl and ethyl. Their relative luminous values and the seconds required to burn one gram are given in the following table:

	Luminosity.	Time.
Acetate of ethyl	1.24	212
Valerianate of amyl	1.03	436
Formiate of amyl	1.01	372
Acetate of amyl, pure	1.00	388
Acetate of amyl, coml	1.00	388
Acetate of isobutyl	.99	373
Formiate of isobutyl	.97	455

Hence it appears that the commercial acetate of amyl may be employed equally with the pure, the price of which at present is about 9d. per oz.—*Mechanical World.*

McDONOUGH'S TELEPHONIC INVENTIONS.[1]

BY PROFESSOR EDWIN J. HOUSTON.

The pioneer work done by Reis in the development of the articulating telephone, quite naturally attracted the attention of numerous investigators and inventors in different parts of the world, and resulted in the production of various forms of apparatus intended for the electrical transmission of speech. Among the earlier investigators in this field the name of James W. McDonough occupies a prominent place.

McDonough came prominently before the scientific men in this country as a party to the famous telephone interference suits, declared in the United States Patent Office during the last eight or nine years. On the 10th of April, 1876, McDonough filed an application in the United States Patent Office for a "Teleloge, or a means for transmitting articulate sounds from one place to another through the medium of electricity." This application was placed in interference with the patent of Bell, dated March 7, 1876, and afterwards with the following applications; viz., that of Edison, of December 24, 1877; Dolbear, October 31, 1877; Richmond, August 24, 1877; Gray, October 29, 1877, and Holcombe, January 28, 1878.

The applications of the above parties, together with those of Berliner, Voelker, Blake and Irwin were placed in interference with Bell and with one another, and formed a long series of interference suits that have not yet been finally decided.[2] McDonough was admitted to the above interferences on the subject-matter of his receiver only. For reasons we shall afterwards refer to, he was excluded by the Office from participation in the other interference suits. The case in which he was a party was known in the Office as case G.

The subject-matter of this case was "Held to embrace a receiver containing an electro-magnet and a diaphragm supported and arranged in close proximity thereto, and adapted to respond to variations in the electric current passing through the coils of the magnet when used in connection or combination with a transmitter adapted to create sound-producing fluctuations in the electric current, whether said electrical variations, waves, pulsations, or undulations represent, or are derived from, sound-waves, or mechanical vibrations."

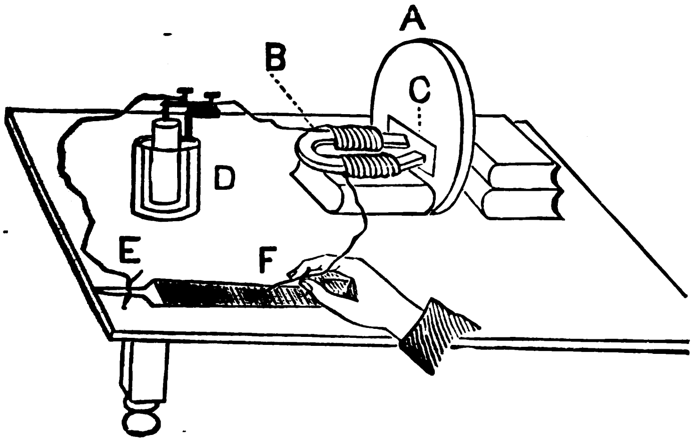

FIGURE 1.—Apparatus of 1867, for obtaining Sounds by Interrupted Currents.

The above interference involved the extremely important issue as to the true inventor of the telephone receiver. After a long and thorough examination of the case it was decided by the Examiner in Interference cases by the awarding of priority of invention to McDonough. On appeal, however, to the Examiners-in-Chief, this decision was reversed and priority of invention awarded to Bell. The case is now on final appeal to the Commissioner of Patents, and awaits his decision.

Although the application of McDonough was made on the 10th of April, 1876, or after the issue of Bell's patent, of March 7, 1876, yet it was made before the date of Bell's lecture, May 10, 1876, or before the actual introduction or use of his articulating telephone. "So that," says the Examiner of Interferences, "McDonough's efforts in this direction may be regarded as entirely independent of and uninfluenced by Bell's disclosures and inventions."

Before describing McDonough's application of 1876, we will give a brief account of his experiments and inventions leading thereto.

According to a sworn deposition made by McDonough in a telephone suit, his first experiments bearing on the subject of telephony were made in 1867, when he constructed an apparatus by means of which he was enabled to obtain a continuous sound by means of an interrupted current of electricity. This apparatus, which is shown in figure 1, consisted of a horseshoe electro-magnet, B, placed before a paper diaphragm, A, tightly stretched over an iron hoop. On the paper diaphragm, facing the poles of the horseshoe magnet, was attached a small piece of tinned iron, C. The diaphragm and magnet were suitably supported on books and placed in the relative positions shown in the figure.

One terminal of a battery cell was connected with one of the terminals of the magnet coil, and the other terminal, E, of the battery was wrapped around the end of an ordinary file, F. When, now, the free terminal of the horseshoe magnet was drawn over the surface of the file, the makes and breaks thus effected in the battery current, produced fluctuations in the magnetism that corresponded with the fluctuations thrown on the electric current traversing the magnet coils, and thus produced movements in the diaphragm. A movement of contact, effected when the terminal touched the file, permitted the current to flow, and thus resulted in the attraction of the tinned iron to the magnet. A movement of the contact away from the file, causing a break in the circuit, permitted the diaphragm to move from the magnet in consequence of its elasticity. With this early apparatus, McDonough was able to produce sounds that were audible at a distance of several feet from the diaphragm. The pitch of the sounds produced, of course varied with the rapidity of motion of the wire over the file. Unfortunately McDonough does not appear to have preserved this early form of apparatus. All of it that remained in his possession in 1876, was the magnet, and the iron ring on which the paper diaphragm was stretched. Nor does he appear to have shown this experiment to others. At least he brings no witnesses to testify to having seen the parts assembled in the relations shown in figure 1.

Assuming, as we may fairly do, when taken in connection with subsequent apparatus that was shown to competent witnesses, that McDonough actually produced the combination of parts shown in figure 1, at the date alleged; viz., in 1867, then *great* credit is due him for the decided invention thus effected, since he has produced what may be fairly regarded as a new combination of parts whereby improved results can be obtained. For, when, at a later date, he placed such a magnetic diaphragm in combination with a telephone transmitter varied by the voice, he did much to place the articulating telephone in its present successful commercial position.

When we speak of the preceding combination of parts being novel when used to produce sounds by means of varied currents of electricity, we are not unmindful of the experiments of Page, in 1837, who obtained musical sounds from a magnet when an interrupted current was passed through a flat spiral placed between the poles. These early observations, which were confirmed by more extended experiments of De la Rive, and of Delezenne, were ascribed to molecular changes in the iron during its magnetization

1. *Journal of the Franklin Institute.*

2. On March 3, 1885, after the above was written, the Commissioner of Patents rendered a decision awarding the priority of invention to Bell on all matters of importance, including the receiver which the Examiner of Interferences originally awarded to McDonough. This decision is final so far as the Patent Office is concerned. [*Editor.*]

Digitized by Google

and demagnetization. In the McDonough experiment, the movements of the diaphragm producing the sound are not molecular, but mass vibrations. The entire diaphragm moves to or fro under the variations in the magnetic attraction. It is such a form of diaphragm that practice shows to be so valuable when used as a receiver for the articulating telephone. McDonough does not appear to have done anything more with his apparatus than to have tried its capacity for producing sounds, more or less continuous, by the action of an intermittent current. Although he may have vaguely conceived the possibility of applying the apparatus to the transmission of articulate speech, yet such conceptions do not seem to have taken definite form until August 26, 1871, when he made the sketch that is represented in figure 2.

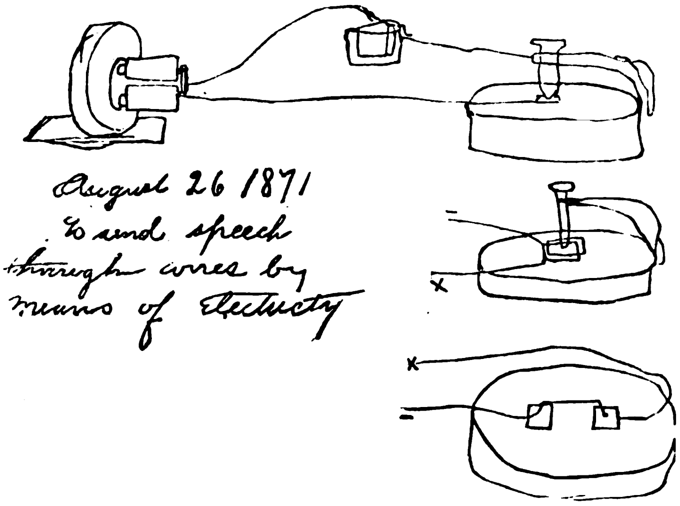

FIGURE 2.—McDonough's Sketch of August 26, 1871.

This sketch, which was made in a memorandum book containing sketches and suggestions respecting some thirty different inventions, was the result of an idea conceived by McDonough after reading descriptions of the phonautograph, and of the Reis telephone. The legend of the sketch, "To send speech through wires by means of electricity," clearly indicates the purpose of the apparatus. No other description accompanies the drawing, and in interpreting it we must bring to bear on it such a knowledge of the state of the art only, that it is fair to suppose was possessed by McDonough at the time he made the sketch. As to the apparatus shown on the left hand, its purpose is obviously the same as that of the experiment of 1867. The apparatus shown in the middle of the upper drawing is clearly a battery, since it is stated that the combination of parts is to be operated through the agency of electricity. As to the various forms of apparatus shown on the right hand of the sketch, they are apparently diaphragm-transmitters of the Reis type, designed to be used in the manner fully described by Reis. Moreover, the apparatus shown in the lower, right hand sketch is substantially the form of transmitter figured in his application of April 10, 1876. Since McDonough was acquainted with the experiments of Reis, and had experimented as to the ability of a magnetic diaphragm to be set into motion by means of a varied electrical current, it is fair to suppose, admitting the credibility of the sketch, that he intended to combine his magnetic diaphragm, with a voltaic battery and a modified Reis transmitter. McDonough does not appear to have actually embodied his invention in a working model until the latter part of May, 1875. This delay was owing to ill health, change of residence, and great press of other business. In May, 1875, however, he constructed his first telephonic apparatus. The membranes of the transmitting and receiving instruments were stretched over the ends of two cylindrical tin cases. A piece of tinned iron was fastened on the diaphragm of the receiving instrument, and the poles of an electro-magnet were placed in proximity thereto. Near the centre of the diaphragm of the transmitting instrument was secured a small piece of tin-foil. This diaphragm was suitably supported in a horizontal position. A needle, passing through a glass tube supported in a vertical position over the diaphragm, rested with its lower end on the plate of tin-foil. The needle was free to move up and down, and formed one of the terminals of a battery, the other terminal being connected with the line. This form of apparatus was somewhat modified in June, 1875, when the form given to it was as shown in figure 3.

In this form of apparatus the tin-foil was replaced by a small plate of german silver. A, represents the tin-can receiver, with its diaphragm, C, and plate of tinned iron, E. The electro-magnet, F, is adjustable with reference to the diaphragm. The transmitter consists substantially of the tin can, B, on the diaphragm of which is placed the german silver plate, H. The glass tube, J. contains the contact needle. The connections with the battery, G, are as shown. With the preceding apparatus, familiar tunes were successfully transmitted, but no words.

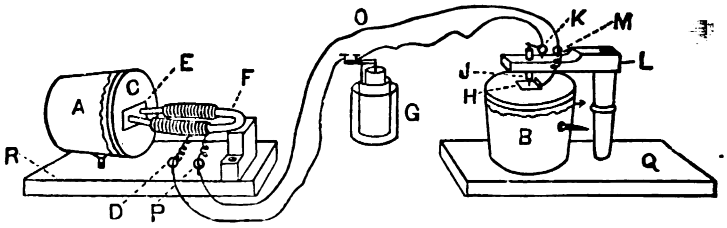

FIGURE 3.—McDonough's Telephonic Apparatus of June, 1875.

Figure 4, shows the details of a modified form of apparatus constructed by McDonough later, in June, 1875. The membrane, A, is stretched over an iron hoop. B, is an iron plate, fastened to the diaphragm. The electro-magnet, C, is securely mounted, in the position shown, on an adjustable standard.

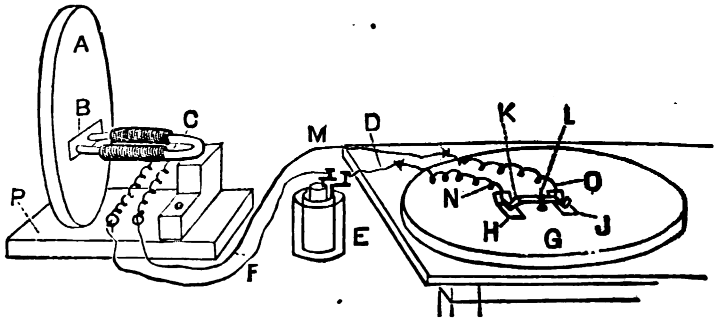

FIGURE 4.—McDonough's Later Telephonic Apparatus of June, 1875.

The transmitter consists of a parchment diaphragm, G, stretched over an iron hoop or ring. Two metal plates, H and J, of german silver, are securely attached to the diaphragm, about an inch and a half apart and connected with the wires, N, and O, as shown. A light strip of metal, K, bent in the form shown, rested on the metallic plates, H, and J, and completed the electric circuit between them. The bolt, L, with a nut for adjustment, was subsequently added in order to prevent the vibrations of the diaphragm from moving the metallic bridge, K, away from the metal plates, H, and J. One of the above mentioned iron hoops was the one employed in the experiment of 1867.

The above apparatus, which was completed about the middle of June, 1875, was successfully employed for the transmission of articulate speech on many occasions during the same month. A number of witnesses testify to having heard articulate speech by the use of the preceding instruments. Only parts of the apparatus of June, 1875, were

Digitized by Google

preserved. These were used as exhibits in the United States Patent Office interference case with Bell and the other parties mentioned. The instruments, however, were reproduced with all the exactness possible, and are represented in figure 5. This apparatus has been successfully used by several parties for the transmission and reproduction of articulate speech.

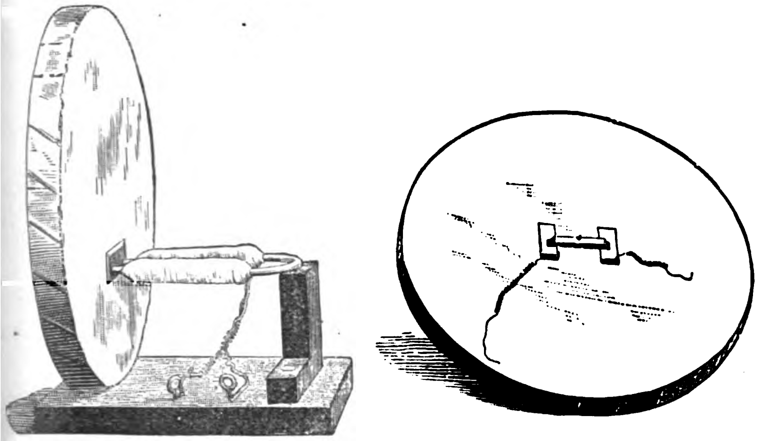

FIGURE 5.—Reproductions of McDonough's Telephone of June, 1875.

Having satisfactorily shown the capability of his instruments to transmit articulate speech, McDonough set to work to improve the strength of the sounds reproduced by the receiver. Prior to the filing of his application for a patent on the 10th of April, 1876, he constructed and carried on numerous experiments with some 15 different instruments, frequently interchanging the transmitters and the receivers.

We will describe a few of the more important of these early forms of articulating telephones. Figure 6, shows an instrument constructed and used by McDonough in September, 1875.

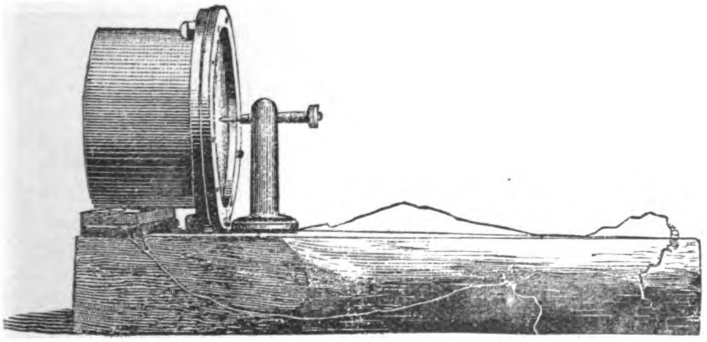

FIGURE 6.—McDonough's Metallic Diaphragm Transmitter, September, 1875. (Exterior.)

The diaphragm in this instrument is mounted on a brass cylinder, and unlike the previous diaphragms, is metallic, being made of a thin sheet of german silver. The arrangement by means of which the diaphragm is firmly clamped in position on the end of the brass cylinder, is shown in the drawing. Directly opposite the centre of the diaphragm an electrical conducting cylinder, or electrode, was supported so as to be in contact with the diaphragm at one of its ends. This electrode was supported by the vertical post placed in front of the diaphragm, and was furnished with an adjusting screw so as to permit its position as regards the diaphragm to be varied at pleasure. The too free vibration of the diaphragm was prevented by means of a screw whose bearing was in a transverse bar. This clamping device is shown in a rear view of the same apparatus in figure 7.

One of the circuit wires was connected with the metallic diaphragm and the other with the contact electrode. Various materials were employed for the contact electrode, such, for example, as nickel, german silver, platinum, steel and carbon. The latter, which appeared to give the best

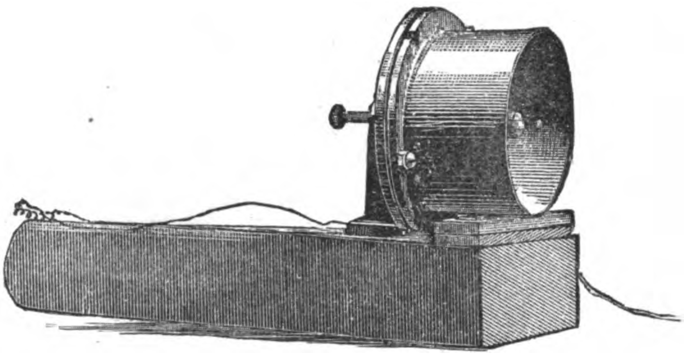

FIGURE 7.—McDonough's Metallic-Diaphragm Transmitter, September, 1875. (Interior.)

results, was formed of the graphite of an ordinary lead pencil. The transmitter of September, 1875, was used in connection with the receiver of June, 1875, as well as with other receivers.

A later form of transmitter and receiver was constructed by McDonough in October, 1875, and named by him "The tin-drum pendulum" instruments. These instruments are shown in figure 8.

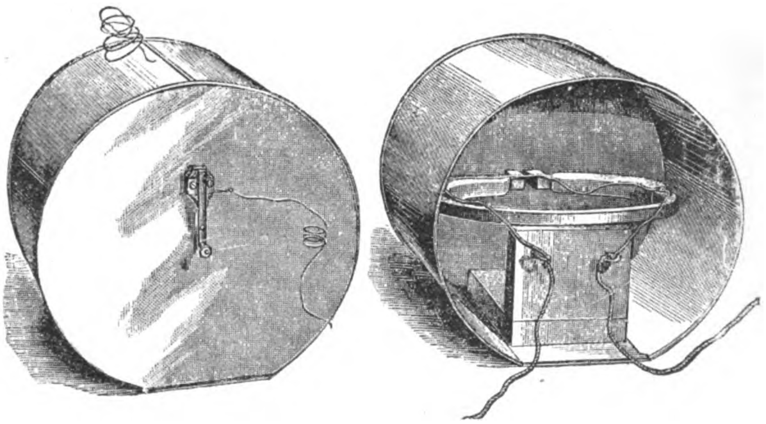

FIGURE 8.—McDonough's Tin-Drum Pendulum Transmitter and Receiver, October, 1875.

The transmitter of this set of instruments consisted of a tin-drum or cylinder flattened on one side, and enclosed at one end, which formed a diaphragm; at the centre of this diaphragm a small piece of platinum was soldered and formed a contact point for an electrode, which, as before, was formed of various materials such as platinum, steel, brass or carbon. The electrode was "inserted in a socket formed in the end of an adjustable screw, which was carried by a hinged pendulous bar of brass, about two and one-half inches in length. The pendulous bar was so hinged as to press the electrode in towards the platinum." The details of this device will be the better understood from an inspection of figure 9, which shows another view of the transmitter. The hinged end of the pendulous brass bar was supported on any insulating material. One terminal of the line was connected to the pendulous bar and hence to the contact electrode, and the other end to any part of the tin-drum, and therefore to the platinum plate.

The receiver, which is shown on the right hand in figure 9, consisted like the transmitter, of a tinned-iron cylinder, closed at one end, and flattened on one side. Inside the cylinder, suitably supported on an upright stand, was placed an electro-magnet, with its poles in close proximity

Digitized by Google

to the tinned-iron diaphragm. The above instruments successfully transmitted and reproduced articulate speech, but, as might be supposed, the resonance of the apparatus somewhat interfered with the distinctness of the articulation.

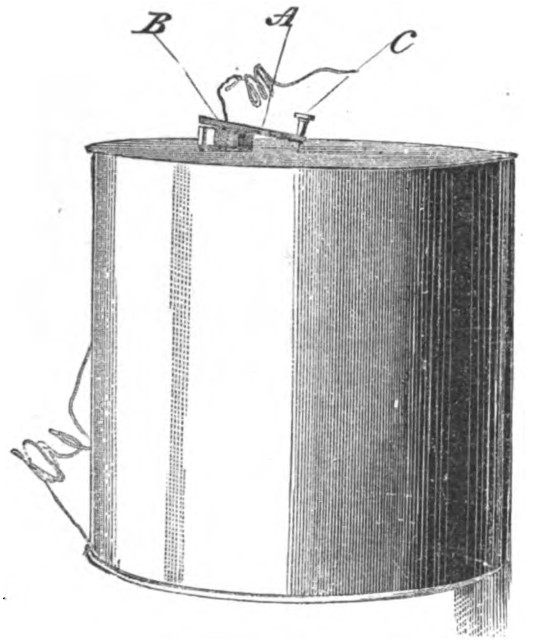

FIGURE 9.—McDonough's Tin-Drum Pendulum Transmitter.

A subsequent set of instruments known as "The brass-drum" instruments, are shown in figure 10.

A brass cylinder, A, has a membrane tightly stretched over one of its ends by means of the tightening ring, B, and the adjusting screws C. An adjusting screw and its socket-electrode are placed, as shown at the centre of the diaphragm. A wooden ring, G, is provided for supporting the tightening ring and diaphragm. The instruments rest on the under base, H. The hinged doors in the instruments are provided for the adjusting of an electro-magnet placed inside each drum, with its poles near a metal plate secured to the under side of the diaphragm. As in the previous instruments, various forms of electrodes were employed in connection with the adjusting screw. Since each of these instruments was provided with an electro-magnet, either could be employed alternately as transmitter and receiver.

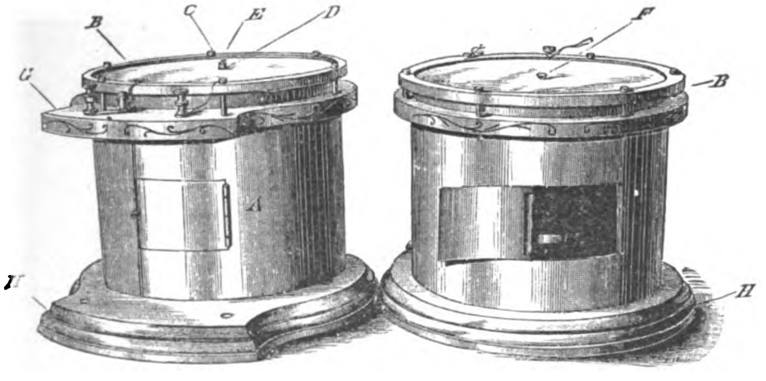

FIGURE 10.—McDonough's Brass-Drum Telephone.

Having thus briefly traced the progress of the invention as claimed by McDonough, and testified to by competent witnesses, we will now discuss the apparatus which was described, and figured in connection with his application in the United States Patent Office, on the 10th of April, 1876, together with the working model that accompanied said specification. The drawings that accompanied this specification are shown in figure 11.

"In figure 1," is shown a perspective view of the "teleloge."

"Figure 2," represents a section taken on the line *xx*.

"Figure 3," represents a vertical transverse section taken on the line *yy*.

"Figure 4," is a general top view of the same.

Quoting the language of the specification: "The object of my invention is to provide a means for transmitting articulate sounds from one place to another, through the medium of electricity, and it consists in the combination with an electrical battery, circuit wires, armature, magnet, and circuit breaker, of a transmitting and a receiving membrane or sounding apparatus, so constructed as to vibrate in accord with the vibrations of articulate sound, and so arranged relative to the magnet and circuit-breaker that the vibrations of the transmitting membrane or apparatus, produced by articulate sounds, are transmitted by the electrical current to the receiving membrane or apparatus, and so as to cause a like vibration of the receiving membrane or apparatus, and to cause it to reproduce the articulate sounds transmitted from and by the transmitting membrane or apparatus. My invention also consists in the novel construction of the circuit breaker, as is hereinafter more fully described."

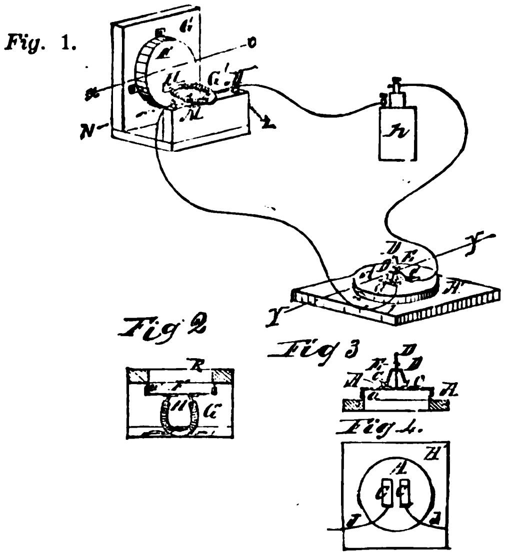

FIGURE 11.—McDonough's Drawings accompanying specification of Letters-Patent for a "Teleloge," filed April 10th, 1876.

Then follows a description of the drawing. The transmitting membrane or diaphragm, shown at A, is composed of vellum or other suitable material so stretched over a metal hoop, or ring, *a*, as to be capable of being tightened or loosened as desired. C, C, are two metal plates attached to the upper surface of the diaphragm, near its centre, in the relative positions shown, and are suitably insulated from each other. The metal bolt, D, permanently attached at its lower end to the centre of the diaphragm, between the two plates, and insulated from them, passes through an opening in the middle of the arch-shaped circuit-breaker, D′, and is furnished with an adjusting nut, F, that serves the purpose of limiting the movements of the circuit-breaker, D′. The circuit-breaker, D′, consists of an arch-shaped piece of metal loosely secured at its centre on the bolt D, and having its extremities bent upward at each end so as to provide contact-surfaces that rest on the metal plates C, C.

The receiving instrument consists of a diaphragm of vellum or other suitable material "sensitive to the vibrations of sound," stretched on a metal hoop or band a^1, in the position shown. An electro-magnet G^1, is placed with its poles opposite an armature, H, attached to the surface of the diaphragm.

The circuit connections are as follows: viz., one wire

Digitized by Google

from the battery, *h*, is connected with one of the metal plates, C, and the other with one end of the coil of the electro-magnet of the receiving instrument. The other plate, C, is connected with the remaining terminal of the electro-magnet, G'.

The operation of the apparatus as described by the inventor is as follows, viz.: "The transmitting membrane, A, being sensitive to the vibrations of articulate sounds produced thereon, is caused to vibrate in sympathy therewith, thereby imparting an upward movement to the circuit-breaker at each vibration, disconnecting it from the plates, C, C, and alternately breaking and closing the circuit, when the intermittent current alternately magnetizes the magnet G', attracting the armature, H, and causes it, and the membrane, F, to vibrate simultaneously with the vibrations of the transmitting membrane, A, and in accord therewith, and so that the membrane, F, reproduces the articulate sounds transmitted from and by the membrane, A."

The working models accompanying this specification were destroyed in the fire at the Patent Office. A duplicate set of instruments was subsequently made and deposited in the Patent Office in lieu of those destroyed. Another set of duplicates was also made for examination and trial by experts. The details of these models are shown in figure 11.

We have already called attention to the fact that the above application was put in interference with Bell and the other applicants in the matter of the receiver only. This circumstance was due to the fact that the United States Patent Office held to the belief in the "undulatory current theory" as being essential to the transmission of articulate speech. It argued that speech could not be transmitted by make and break currents, and that since McDonough's apparatus described such currents it could not be considered as an articulating telephone transmitter. This singular process of reasoning, which was perhaps only the natural result of an unhesitating acceptance of a theory which can by no means be regarded as unquestionably proved, was maintained despite the fact that the model deposited in the office with the specification and drawings, together with the other apparatus we have described, could and did transmit intelligible, articulate speech, as has been amply testified by experts of unquestionable integrity and ability. No question, however, appears to have been raised as to the ability of the receiving instrument to reproduce sounds of all kinds, including intelligible, articulate speech, so that the Examiner of Interference awarded the priority of invention on this count of the interference to McDonough, above all the other contestants.

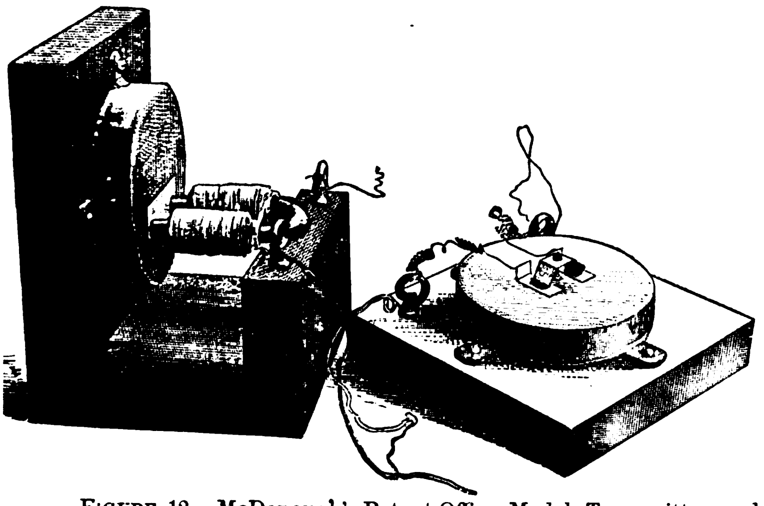

FIGURE 12.—McDonough's Patent Office Model, Transmitter and Receiver, April 10, 1875.

The subject-matter of the interference in case G, on Gray's claim, application of October 29, 1877, is as follows, viz.: "A telephonic receiver consisting of the combination in an electric circuit of a magnet and a diaphragm supported and arranged in close proximity thereto, whereby sounds thrown upon the line may be reproduced accurately as to pitch and quality.

"In the printed record containing the decision of the Examiner of Interferences it is acknowledged that a diversity of opinion exists as to the scope of this claim, and the interference founded thereon. It is claimed, on the one side, the designation, 'A Telephonic Receiver,' together with its prescribed capacity, 'whereby sounds thrown upon the line may be reproduced accurately as to pitch and quality,' is tantamount to a claim for the combination of such receiver with an instrument capable of producing electrical waves or undulations bearing the impress of sound waves.

"On the other hand, it is maintained that the claim is to a described combination of these elements; an electric circuit, a magnet, and a diaphragm; the parts being so disposed and arranged as to manifest, among other functions, the capacity to reproduce sonorous vibrations electrically transmitted, and that the particular means for creating the electric current which is to be translated into sound-vibrations form no limitation upon the invention."

The Examiner-in-Interferences adopted the view that the issue embraced the telephone receiver alone, and on this construction of the issue awarded the priority of invention to McDonough. The Examiners-in-Chief, however, to whom, as we have already remarked the case was appealed, adopted the view that the issue clearly necessitated the combination with the receiver of a transmitter capable of throwing on the line the peculiarities of articulate speech. On the assumption that a transmitter constructed as was that of McDonough's could not transmit articulate speech, and that therefore the combination of such a transmitter with a diaphragm receiver was not effected, the Examiners-in-Chief, awarded the priority of invention to Bell. The above, as we have already remarked, was the natural conclusion, in view of the belief of the Examiners-in-Chief, as to the necessity for an undulatory current for the transmission of articulate speech.

There appears to be ample testimony by the most able experts that apparatus constructed in accordance with the McDonough specification of April 10, 1876, can and does clearly transmit intelligible articulate speech. McDonough's apparatus combines with a magnetic diaphragm receiver, what may, perhaps, be regarded as a variety of Reis transmitter. If then it be admitted that the Reis transmitter had never previously transmitted intelligible articulate speech, which we deny, then since it does transmit it when coupled with a magnetic diaphragm receiver, it might appear that the essence of the invention of the articulating telephone consisted in the invention of a suitable receiver to be used in combination with a Reis transmitter.

No little probability would appear to be given to this view, from the generally acknowledged fact that Reis transmitters operate very satisfactorily when combined with magnetic diaphragm receivers.

It is, indeed, in our opinion, an open question whether the real improvement in the art that placed the telephone as left by Reis in the extensive commercial use it now has, did not in reality consist rather in the invention of a more suitable receiver than it did in any modification the Reis transmitter has since received. We can readily understand how a current, modified by the action of the human voice on a Reis transmitter, would produce in a magnetic diaphragm such undulations in its magnetic field as would result in the movements necessary to reproduce the articulate speech thrown on the transmitter.

Such a view, it will be seen, takes the assumed necessity for the undulatory character, in the somewhat narrow sense in which it is generally construed, from the electric current transmitted, and places it in the transmitting and receiving diaphragms, so that the movements of the re-

Digitized by Google

ceiving diaphragm would still be an exact reproduction of those of the transmitting diaphragm.

When describing the inventions of Reis, we will discuss at greater length the peculiarities of the electrical currents transmitted in telephony.

CENTRAL HIGH SCHOOL,
PHILADELPHIA, February 14, 1885.

ABSTRACTS AND EXTRACTS.

TEST OF THE EDISON-HOPKINSON DYNAMO.

Messrs. Mather and Platt, of Salford, have furnished to *Engineering*, the following account of a prolonged and practical trial of an Edison-Hopkinson dynamo constructed by them and designed to give a current of 250 amperès with an electromotive force of 55 volts.

DESCRIPTION OF MACHINE.

The dynamo is of the latest Edison-Hopkinson type with a short armature. The exterior dimensions are, length, 56 in.; breadth, 36 in.; and height, 60 in.; and the net weight of the machine complete is 32 cwt.

The commutator is of copper with mica insulation, and has 40 bars; and is provided with double brushes independently adjustable. The magnets are shunt-wound.

	Ohms.
The magnet resistance is	7.54
The armature resistance is	0.009

The dynamo is designed for a continuous load of 250 amperès, and 55 volts, and to run at a speed of 900 revolutions per minute.

The efficiency of the machine is deduced from the following figures :—

	Watts	Horse-power
Total electrical power developed	16,246	21.78
Loss in magnets	401	0.54
" armature	720	0.96
Power available in outer circuit when run as in test	15,125	20.28

Hence,

	Per Cent.
Electrical Efficiency	93.1
Loss in magnets	2.4
" armature	4.5

The following are particulars of the test to which this machine has been subjected :

The dynamo was arranged for driving by an ordinary strap from a double cylinder engine made by Mather and Platt, and carried on slide rails to admit of the belt being tightened if required. One of Sir William Thomson's graded potential galvanometers was permanently coupled to the machine to give a continuous indication of the electromotive force between the terminals, and arrangements were made for measuring the current by means of a current galvanometer also of Sir William Thomson's graded type.

The temperatures of the bearings were measured throughout the test by means of thermometers placed in mercury cups attached to the bearings, and a continuous record was kept of the temperature of the room.

The speed was indicated by a tachometer attached to the engine, and the revolutions of the dynamo counted from time to time with a counter.

The load was maintained constant throughout the test, as nearly as possible at 275 amperès, and 55 volts, measured at the terminals. This is 10 per cent. above the normal load for which the machine is intended.

The machine was started on December 30th, and run for five hours, when the temperatures were taken as follows :

Room, 17 deg. C.; pulley bearing, 35 deg. C.; commutator bearing, 36 deg. C.; magnets, 33 deg. C.; armature, 76 deg. C.; commutator, 70 deg. C.

At the end of 12 hours run the temperatures were again taken :

Room, 20 deg. C.; pulley bearing, 36 deg. C.; commutator bearing, 34 deg. C.; magnets, 33 deg. C.; armature, 84 deg. C.; commutator, 75 deg. C.

Again at the end of 24 hours the temperatures were : Room, 15 deg. C.; pulley bearing, 30 deg. C.; commutator bearing, 29 deg. C.; magnets, 33 deg. C.; armature, 76 deg. C.; commutator, 74 deg. C.; Showing that at the end of 12 hours the maximum temperatures had been reached in all parts of the machine. Subsequently, throughout the entire run of three weeks' duration, the temperatures did not vary more than was accounted for by variations in the temperature of the room.

The speed maintained throughout the run varied from 910 to 925 revolutions, with the full load, and the armature and magnets warm.

The machine was run continuously, stopping ten minutes daily to read the temperatures of the armature and commutator, and for Sunday, until January 6th, when it was stopped in order to take out the armature and have it examined to determine if there were any sign of charring or deterioration in the insulation of the wire ; and in order carefully to examine the commutator. The examination was conducted by Mr. Blackburn on behalf of the Edison and Swan United company, and no change whatever was observable either in the insulation of the wires of the armature or in the commutator.

It was then decided to run the machine absolutely continuously for a fortnight without any break whatever, with the full load of 275 amperès. This test concluded on January 20th.

Throughout the whole of this continuous run for 14 days there was never the slightest sparking at the commutator, the bearings and magnets remained at a uniform temperature throughout, and the temperature of the commutator at the end of the run was 79 deg. C., practically the same temperature as at the end of 12 hours. One set of brushes were used without change of adjustment for 12 days, and at the end were found to be worn down uniformly 1-16 in.

The commutator was perfectly smooth, and showed no signs of wear or grooving, and the armature had stood the run without the slightest swelling or any sign whatever of change in the insulation.

These tests were undertaken by Mather and Platt at the request of the Edison and Swan company, in order to show the durability of the Edison-Hopkinson dynamo under a long and continuous strain with a load of 10 per cent. in excess of that for which the machine is sold. The conditions of the test were formulated by Mr. Albright and Mr. Blackburn on behalf of the Edison and Swan company, and it was superintended by them and their representative, Mr. Creagh, during the entire run.

It proved conclusively that a dynamo of this type may be run continuously without any change in its working parts or deterioration in the insulation of the copper conductors or change in their resistance, and that the wear is exclusively confined to the commutator and copper brushes, and that, with regard to the former, three weeks' run is not sufficient to produce any visible wear, and that the brushes last much longer than is usually supposed, one set being capable of lasting a year on a machine running on an average three hours a day.

ELECTRIC LIGHTING IN AMERICA.[1]

No part of the expert evidence submitted to the Parliamentary Committee impressed the members of the committee more strongly than that elicited from American witnesses. The lucid and confident manner in which the cost of lighting a square mile of London at a little under $485,000 was set forth, gave a high idea of the extent and success of transatlantic achievements in electric illumination. Not for the first time, John Bull was deceived, not

1.—This article from the London *Statist*, Nov. 15, 1884, has been frequently referred to in America. By request we publish it in full, substituting the decimal for sterling denomination.

Digitized by Google

only as to the actual facts relating to the condition of things electrical in English cities, but also as to the state of affairs across the Atlantic. Facts were either misrepresented or withheld.

We have lately had the opportunity of examining, from unimpeachable sources, the cost and revenue of the only electric-light station in the world which has seriously undertaken the task of competition with gas. We propose, therefore, to give our readers a brief history of this station from its foundation two years ago, with the financial results at the present time. Financially supported by the firm of Drexel, Morgan and Co. and many of their clients and supporters—to the exclusion, however, of Messrs. J. S. Morgan and Co., who from the first declined any financial connection with the concern—Mr. Edison opened in New York, in September, 1882, the First District Illuminating Station. This portion of the empire city is the most densely populated part of the business or "down town" quarter. The area lighted is contained in a square of 2,400 feet, and has, therefore, an area of something less than a quarter of a square mile. The district contains about 50 blocks of buildings, and is intersected by some 15 streets or passages. The necessary permission to open the streets to lay the electric mains was obtained, not by Act of Congress or by other legislative or official means, but by the simpler and perhaps less costly method of a payment to Tammany. The sum which passed amounted to about $48,500, and in exchange for this payment the Edison company is free to tear about the streets whenever it pleases it so to do for electric lighting purposes. On September 4th, 1882, the station was started with 2,323 lamps, contained in about 85 houses. These lamps have increased in number until last month 12,540 lamps had been installed, the present capacity of the station being now attained. The largest number of lamps ever burning at one time was 5,530 in January of this year, and their average life, based on about 12,000 renewals, is a little more than 400 hours. Shortly after the installation of the station, it was found that some customers did not require the light in the summer, and that consequently their custom involved loss. It became necessary, therefore, to cull from among the customers those whose demand was less than an average of 2¾ hours per day for every lamp connected on their premises. If their consumption fell short of this standard, they were quietly got rid of, so that the actual average consumption of light per lamp was artificially raised above the normal gas average of the district. This process of natural selection in New York is important, because, under the English Act, a customer using but half an hour's light in a month can not only claim to be supplied, but must, under grave penalties, be supplied by the unhappy company. During the first year little money was received from customers, partly owing to the novelty of the enterprise, and partly owing to a natural desire on the part of the management that criticism should be disarmed before claims were lodged for the amount of the lighting bills. The cost of gas in the First District of New York is about $2.25 per 1,000 cubic feet. Competition, therefore, with the elder illuminant, having regard to the power of picking the good customers, and of unreserved access to the streets, was rendered distinctly favorable. Added to this was the fact of Mr. Edison's presence, and the supply of ample funds for the purposes of the momentous experiment. These favorable elements notwithstanding, the financial result, when viewed from an impartial standpoint, is not only disappointing, but absolutely and finally disposes of any idea that electric lighting in England contains the germs of remunerative investment. Before giving the figures of the capital investment, running expenses, and revenue, it must be premised that the management of the station has been—at any rate during the period over which the returns in our possession extend—able, economical, and efficient. Not only is American genius more suited to the *exploitation* of new industrial developments than that of older countries, but there is a general disposition to help along a new scientific undertaking, which is signally wanting in England. The cost of the station is somewhat in excess of $970,000, and the annual expenditure is at the rate of nearly $77,600 a year, without allowing for depreciation, sinking fund, or interest on capital. The excess of receipts over actual cash outlay amount to about $29,100 a year, or 3 per cent. on the capital invested. When, however, a due allowance is made for unforeseen contingencies, such as the bursting of a boiler or other heavy casualties, it will be seen that the alleged profit is illusory, and if, at most, expenditure is equal to revenue, it is certainly not less. In order to appreciate the precise nature of the result of this experiment, it is necessary to suppose that each glow lamp is replaced by a five-foot gas-burner, and that the amount of gas consumed to produce an equivalent of light be computed. The result of this calculation gives $1.73 as the cost per 1,000 feet of the gas thus consumed. If, however, a 16-candle lamp be held to compete with a seven-foot gas jet, then the equivalent is as nearly as may be $1.21 per 1,000 cubic feet. To compete with gas at 73c, the cost of maintenance—*i. e.*, of production—must be reduced by two-thirds. On examining the means of reducing the cost of establishment, there is no reason to doubt that an equally efficient plant could be laid down in England for half the sum expended in New York; but it is improbable that the cost of maintenance can be seriously diminished. From the foregoing, it is clear that such stations as the Victoria and Holborn installations, established by the Swan and Edison companies respectively, or the Colchester experiment of the South-Eastern (Brush) company, must inevitably lead to a permanent consumption of the available resources of the companies in question. Finally, we are driven to the conclusion that, so far as central station lighting is concerned, the prospects in England are hopeless until a radical improvement in principle has been effected; and boards of directors maintaining the contrary, in the face of the experience gained on both sides of the Atlantic, incur a responsibility which, for our part, we are disinclined to share.

PLATINUM AND ITS PECULIARITIES.

The fact that nearly every description of electrical apparatus embraces, among the materials used in its construction, a certain amount of platinum, has made the name and appearance of this metal familiar to the merest tyro in electrical science. Its origin and some of its peculiar characteristics are, however, not so generally known, but will be found of interest to those who desire to become familiar with the various branches of industry indirectly connected with their avocation.

The platinum business of the United States is in the hands of a few firms, and the demand for the metal is now so brisk that it is with difficulty that sufficient quantities of it are obtained. Nearly the entire supply comes from the celebrated mines of the Demidoff family, who enjoy a monopoly of its production in Russia. The raw material, as it arrives in this country, is already refined, and formed into sheets of various grades of thickness, also into different sizes of wire. In order to meet the requirements of our mechanics, however, it is frequently necessary to change these sizes, which is readily effected by the ordinary processes of rolling or drawing. At one time Russian coins were made from the metal, but it is no longer used for this purpose. Limited quantities of platinum ore have been brought from South American mines, and successfully refined. As yet it has been found only in Colombia; but the mineral regions of South America have not as yet been thoroughly examined, and it may eventually be found in other states. It also exists in the remoter portions of British Columbia, near the sources of the Peace River, and samples found in Montana have been tested in New York.

There is a popular supposition that it ranks with gold in intrinsic value. It did at one time nearly reach that point, but it is now worth from $8 to $12 per ounce, according to the form in which it is required, or the amount of alloy it contains. Iridium is used as its alloy, which hardens it, and renders it more difficult to work. Pure platinum is as soft as silver, but by the addition of iridium it becomes the hardest of metals. Its infusibility is the most serious obstacle to its manipulation. A temperature which will melt any ordinary metal has not the slightest effect upon it. If we place a platinum wire, no larger than a hair, in a furnace where ingots of steel are being melted all around it, it will come out absolutely unchanged. The melting temperature of platinum alone, has not been accurately determined, yet singularly enough, if a piece of lead be placed in the crucible with the platinum, both metals will melt together, at the comparatively low temperature at which lead becomes fluid. If a piece of lead be melted in a platinum crucible, as soon as the lead melts the platinum follows, and the crucible is destroyed.

Among other peculiar characteristics of platinum is its extreme ductility. A wire can be drawn from it to a smaller diameter than from any other known metal; in fact, so thin as to be invisible to the naked eye, which renders it useful for cross wires in optical instruments. Draw-plates for the ordinary finer sizes of wire are formed of rubies and sapphires. The process of drilling such small holes in these hard stones, is a very delicate one, and is esteemed a trade secret. Still more delicate, perhaps, is the filing down to a long tapering point, the end of a wire $\frac{1}{1800}$ of an inch in diameter, so that it may be passed through a draw-plate, which will reduce its size still more, it being then started by catching the end with a pair of nippers. This fine wire is used also for surgical purposes, in which it is heated to incandescence by an electric current, searing the flesh as it cuts, thus preventing the loss of blood, the operation being also painless.

The precious stones for draw-plates are prepared by a Swiss lady in New York city, who has followed the business for over 30 years. It was a very lucrative trade at a time when filigree gold jewelry was in fashion. The plates were then worth from $2.50 to $15, according to size. The stones used are not the most finely colored, but they must be free from flaws. These are cut by a lapidary into small discs, after which the hole is drilled through by hand—funnel shaped, and barely perceptible at its smallest point. It must be perfectly smooth, and of an accurate gauge. When finished, such draw-plates, if carefully used, are practically indestructible.

Many attempts have been made to find an efficient substitute for platinum, for the contact points of electrical apparatus, but with at least only partial success. The consumption of platinum for the terminals of incandescent electric lamps is already becoming an important item, and bids fair to increase almost indefinitely.

THE TELEPHONIC TELEGRAPH.

The Toronto *Globe* of February 13, gives the following description of the test of a recent Canadian invention. Yesterday afternoon at about six o'clock a test was made at the office of the G. N. W. Telegraph Co. in this city of the recent invention of Dr. A. M. Rosebrugh and Mr. G. Black, of Hamilton, by means of which telephonic and telegraphic messages can be exchanged through long distances on the same wire simultaneously. A member of the *Globe* staff held a conversation with the *Globe* correspondent in Hamilton, the voice of the one being distinctly recognizable by the other even when dropped to a whisper that was inaudible to a person a few feet away from the whisperer. While the telephone messages were being exchanged, Mr. Toye, of the G. N. W. company, sent from his end on the same line a telegraphic message, which was immediately repeated by telephone from the Hamilton end. The main virtue of the invention consists in the entire suppression of the induction, which is such a nuisance on the ordinary telephone. For instance, everybody who has occasion to use the telephone in Toronto after nightfall knows that the noise caused by induction from the electric light wires is such, on wet nights especially, as almost to render conversation inaudible. Dr. Rosebrugh illustrated his invention by disconnecting the telephone instrument for a few moments from the appliance which suppresses the induction. Straightway the familiar buzz of the electric light company's dynamo was heard. Restoring the connection, the noise from the dynamo ceased to trouble. When the telegraphic signals were being sent over the line there was no inconvenience whatever felt by the listeners. The wire used for the test was one which passes from the G. N. W. Telegraph Co.'s office up Church street and Queen along through a perfect maze of telegraph wires, and for two miles on the same poles with the electric light wires.

THE CHINESE ACOUSTIC TELEPHONE AND PHONOGRAPH.

At the last meeting of the China Asiatic Society at Shanghai an instrument, which was a species of primitive telephone, was presented for inspection by Dr. Macgowan, of Wenchow. It consisted of two bamboo cylinders, from one and one-half to two inches in diameter and four inches in length; one end of each was closed by a tympanum of pig bladder, which was perforated for the transmitting string, the latter being kept in place by being knotted. This rude instrument is called the "listening tubes," and is employed for amusement as a toy, conveying whispers 40 to 50 feet. It is unknown in many parts of China, the provinces of Che-kiang and Kiangsu being the only ones, so far as can be ascertained, where the listening tubes are employed. Besides this toy, Chinese ingenuity produced, about a century and a half ago, the "thousand mile speaker." This instrument is described as "a roll of copper, likened to a pipe, containing an artificial device; whispered into, and immediately closed, the confined message, however long, may be conveyed to any distance, and thus, in a battle, recent instructions may be conveniently communicated. It is a contrivance of extraordinary merit." The inventor of the "thousand-mile speaker," one Chiang Shun-hsin, of Huichou, flourished during the reign of Kang-hsi, during parts of the 17th and 18th centuries. He wrote on occult science, astronomy, and foreign physics, and the above description of his invention was copied from his works into a provincial encyclopædia. At the time the latter work was published—in the reign of Kien Long—there was no longer an instrument of this kind in the province, as the ingenious invention appears to have perished with the student who contrived it.—*Nature.*

THE ELECTRO-CHEMICAL EQUIVALENT OF SILVER.

A very careful and important determination of the electro-chemical equivalent of silver has been made at the Observatory of the Physical Institute of Wurzburg, and the results are that an ampère current following for one second, or one coulomb of electricity, deposits 1.1188 milligrammes of silver or 0.3281 milligrammes of copper, and decomposes 0.09328 milligrammes of water, a result agreeing closely with that of Lord Rayleigh, recently communicated to the Physical Society. An ampère therefore deposits 4.0259 grams of silver per hour; Kohlrausch's value is 4.0824, which has hitherto been universally accepted. This value is so useful in accurate measurements that it is eminently satisfactory to find the new determination agreeing so closely with that of Lord Rayleigh, which will probably be adopted by English electricians.

LITERATURE.

REVIEWS.

Dynamo-Electric Machinery; a Manual for Students of Electrotechnics. By SILVANUS P. THOMPSON, B. A., D. Sc. E. & F. N. Spon, London and New York, 1884.

In the autumn of 1882, Professor Thompson delivered a series of lectures before the Society of Arts in London, on dynamo-electric machinery. These lectures were soon afterwards published in the Journal of the Society, and were subsequently reproduced in several European technical journals, and also in pamphlet form. Every student and investigator of dynamo-electric machinery into whose hands these lectures came was at once impressed with the originality, the completeness and the great practical value of Professor Thompson's labors. The subject was at that time but imperfectly understood, even by otherwise well informed electricians. The diverse forms in which the machine had already been embodied by the ingenuity of numerous inventors were so numerous as to defy satisfactory classification, while the application of any general method of mathematical investigation seemed to be almost an impossibility. The method of treatment which was adopted by Professor Thompson was radically different from that of any of his predecessors. His happily conceived plan of logically grouping the various dynamos in connection with certain typical and characteristic forms was executed in a manner which exhibited an unusual grasp of mind and power of analysis. The practical value of such a system of classification is due to the fact that these type forms are fixed in the mind with little effort, and may be at once recognized when appearing in any disguise, thus enabling each new machine which may hereafter appear to be referred to its characteristic type, rendering its comparison with others a matter of comparatively little difficulty.

These lectures were republished in the United States and a French translation also appeared in Paris; the wide circulation thus given to them indicated that they supplied a recognized want, and the author was thus led to prepare the present volume, which although based upon the original lectures is by no means a mere reprint of them. A considerable amount of matter has been added to the original chapters, so that they now contain descriptions of most of the recent inventions of importance. Many other forms of machines, of merely historical interest and obsolete in practice have wisely been omitted. A careful analysis of this treatise upon which an adequate review of its contents could be based, would be a work of much time and labor. We have, however, examined the volume with as much thoroughness as possible in view of the limited time at our disposal, and will call attention to such points as have suggested themselves to us.

In the preface the author observes that "there is no such thing yet as a best dynamo," but that like a voltaic battery some are best adapted to one use and some to another. This comparison is a mistaken one. It can hardly be disputed that the best dynamo for all purposes must be the one which is most "efficient;" which with a given speed, will produce the greatest E. M. F. with the least internal resistance. Experience certainly shows that the dynamo, which when wound for high E. M. F. makes the most efficient arc-light machine, when wound for low E. M. F. will make the most efficient electro-plating machine; that is to say, other things being equal, the best machine for *all* purposes is that, which with a given consumption of h. p. will develop the greatest C E and this proportion must necessarily hold good irrespective of the relative values of C and E.

The fundamental classification of dynamos proposed in chapter ii., while unquestionably a radical improvement upon those based upon arbitrary and unmeaning distinctions, is not altogether satisfactory. While it is by no means easy to suggest a classification more satisfactory than that of Professor Thompson, which is based entirely upon the characteristics of the magnetic field, yet even this is open to the objection that it necessarily relegates the armature, really the most important part of the machine, to a secondary classification, while some few typical dynamos can be assigned no place within it.

A complete exposition of all the known principles involved in action of the dynamo is given in chapter iii, and the best theoretical and practical forms to be given to the machines are discussed at length, even the smaller details of construction receiving careful consideration. There is much in this chapter which may be studied with great advantage by the designers of dynamo machines. We find however some instances in which it might be wished that the language of the author had been more explicit. For example he says (p. 31) that "there ought to be so much iron in the armature core, that it is magnetized just up to the critical degree of saturation when the machine is generating its maximum current." This is one of the most important points in the construction of the machine, but are we to understand that the armature shall be so magnetized by its own coils, or by the inductive action of the field, or by the difference between these two in favor of the field? Again, is it not the essential function of the armature core to provide such a path for the lines of force that the portion of the field cut by the armature wires may possess the highest possible intensity, and if this is the case, why should not the core be made as large as possible? Some of the statements made in this chapter present an apparent contradiction in terms which the student will find somewhat puzzling. For example (p. 28) the Maxim armature is criticised as having a great quantity of idle wire on its inner surface, and the author then goes on to say in the same breath that the "very excellent machine" of Crompton and Kapp has an armature of the same kind. Again, on p. 38, the author objects to the consequent-pole field as exemplified in the Siemens and Weston machines, which he compares unfavorably with the double magnet used in Deprez's double Gramme dynamo, although the application of that system of field magnets to a single armature machine is not obvious.

In view of the repeated references to the Jürgensen dynamo it would have been well to have included a description of it, but, doubtless by an oversight, the author has omitted to do so.

In chapter iv, a large number of original, interesting and instructive experiments are described, having to do with the induction of electric currents and the distribution of potential in the armature. This portion of the work will repay careful study, and the same may be said of chapter v. The discussion in the last named chapter of the reactions in the armature and in the magnetic field is particularly good. The statements are clear, well-presented and convincing.

In chapter vi, in which is discussed the government of dynamos and the different methods of exciting and maintaining the magnetic field, we find some statements which to say the least appear to be misleading. On page 86 it is said that any of the different methods for maintaining the field may, be applied either in direct-current or in alternate-current machines. It is not easy to see how the "series" system, for example, can be applied to an alternate-current machine, neither can we imagine how the "shunt" system can be applied to it, without commuting the current, or at least a part of it, which would convert the dynamo, either wholly or partially, into a direct-current machine. On page 87 it is stated that if the armature of a "series" dynamo "had no resistance at all, then the current furnished to the system of lamps (in multiple arc) when the armature speed is constant, would be exactly proportional to the resistance of the external circuit." The author evidently intended to say "directly proportional to the number of lamps" or "inversely to the circuit resistance." But is the statement true even with this limitation? Even if a direct-circuit machine had no resistance in its armature, diminishing the external resistance would necessarily increase the current, and this stronger current would flow through the magnet and strengthen the field, thereby increasing the E. M. F. On the other hand if the armature had a sensible resistance, the potential at the terminals of the machine would be reduced when the external resistance was decreased, and this, by neutralizing the augmented E. M. F., due to the stronger field, might aid in maintaining a constant potential at the binding-posts. The very type of machine —the Weston—which it is said in a foot-note, most nearly fulfills this condition, is, as a matter of fact, "shunt" wound.

In continuation of the same subject it is further said, "on the other hand if a shunt-dynamo were constructed with an armature of considerable resistance, the E. M. F. which it would develop at a constant speed would be nearly proportional to the external resistance, for doubling the external resistance would very nearly double the current thrown round the shunt." Possibly an armature might be constructed of such a resistance that this would be the case, but it would necessarily have to be of detrimentally high resistance, and in any case the statement is not true as a general proposition. We think that all practical electric light engineers will agree with us that Professor Thompson is entirely mistaken in the idea which he puts forth with so much apparent confidence, that the shunt-winding is only suitable for a constant current. When the problem is that of the maintenance of a constant E. M. F. with a varying current, as when incandescent lamps are burned in multiple arc, shunt winding is even more effective. If we start with the author's own assumption that the armature is driven at a uniform speed and its resistance is inappreciable, the volume of current must nevertheless vary directly as the number of lamps, and inasmuch as a varying external resistance does not alter the potential at the terminals of the machine, the field must remain constant, and it is obvious that with a constant speed and a constant intensity of field the E. M. F. must also be constant. The practical operation of the machine before cited (Weston's) demonstrates the correctness of this view. We are aware, of course, that if the field were weak so that the current in the armature could react upon it, this would not be strictly true. The fundamental error which Professor Thompson has here fallen into, obviously arises from conviction that a dynamo must of necessity have a sensible armature resistance. On page 90 the "series and magneto" system of Professor Perry, is described—if not with approval—at least without criticism. This system is intended to provide a constant E. M. F., to do which it requires an independent auxilliary magneto-machine with an E. M. F. equal to that required by the lamps, and being in the main circuit this must carry the entire working current. It strikes us that it would not have been out of place for the author to have pointed out the

Digitized by Google

patent absurdity of this organization from a practical point of view.

A good deal might be said in relation to the contents of chapter vi. The author bestows a liberal measure of approbation upon the Crompton-Kapp machine, which may for aught we know be abundantly justified, but it is certain that the reasons given therefor are by no means convincing. Thus it is stated (page 113) that by reason of the great strength of the field there is but little lead to the brushes, and "*what lead there is is absolutely constant.*" Now whatever lead there is, must be due to no other cause than the reaction of the current in the armature, hence if this current is very greatly reduced, as for example by cutting out nearly all the lamps, we fail to understand why this would not necessitate an alteration in the lead. A great deal of space is devoted to the Victoria dynamo, much more than to any other machine. The warm commendation bestowed upon this particular machine may perhaps be taken with a grain of allowance, as we understand that the author took a very active part in its reorganization. Chapters vii, viii and ix contain excellent descriptions of most of the machines actually in use, embracing all the essential types. The analysis and description of the Brush machine—an invention which has fared very badly at the hands of many who have attempted to describe it—is particularly good. We observe that the author has failed to comprehend some of the peculiarities of the Weston machine, as for example, he states (p. 147) that the method of winding the armature with two circuits was adopted in order that an accident to one section should not completely break down the machine. The real reason is to prevent the armature coils from being burned by the accidental short-circuiting of two adjacent sections of the commutator. Two distinct sets of coils alternate throughout the circumference of the armature, which are connected to alternate plates of the commutator in a manner fully described and illustrated on page 240 volume i. of the *Electrician*, now the ELECTRICIAN AND ELECTRICAL ENGINEER. It is also asserted that the Weston incandescent machine is self-regulating simply because its internal resistance is *nil*. While it is true that this circumstance is an important factor in the production of the result aimed at, many other changes in the form and proportion of the machine were found necessary to its successful accomplishment. It was found to be especially important that the inductive influence of the field-magnets, by which the polarity of the armature core is principally determined, shall so greatly preponderate over the magnetic influence of the current in the armature coil as to wholly overcome its effect. By this means the polar line of the armature is brought into close coincidence with the corresponding line of the field, thus causing the actual points of maximum potential upon the commutator to correspond with the theoretical points. This has been done with so much success that the machine may actually be run in either direction without altering the position of the brushes.

Chapters x to xvii treat of the mathematical and geometrical theory of the dynamo. We must leave the discussion of this portion of the work to more competent hands. The author himself, in his preface, says :—

> The true mathematical theory of the dynamo can only be written when the true basis for writing it shall have been discovered. That basis, the exact law of induction of magnetism in the electro-magnet, does not yet exist.........Our coefficients of magnetic permeability and magnetic susceptibility, though convenient as symbols, are little more than convenient methods of expressing our ignorance. We want some new philosopher to do for the magnetic circuit what Dr. Ohm did for the voltaic circuit fifty years ago. Until we know the true law of the electro-magnet there can be no true or complete theory of the dynamo.

Chapters xviii to xxv are devoted to a discussion at length of the dynamo as a motor, and various special forms of motors are described.

The author does not profess to enter into the historical aspect of the subject, although an occasional allusion of this kind may be found, in respect to which the criticism might be made that the author has failed to inform himself as thoroughly as he might have done, of the by no means unimportant work which has been done in the United States in the development of the dynamo-electric machine and the electric motor.

The mechanical execution of the book, with the exception of the binding, is of the best character. The illustrations are original, and are illustrative. They have been introduced with great liberality wherever they could add to the clearness of an explanation, and we are glad to see that the author has not hesitated to repeat one, whenever necessary, rather than to put the reader to the annoyance of turning to another part of the book.

Future editions will no doubt greatly improve this already excellent work, and we have no doubt that it will hold its place as a standard authority on this branch of electrotechnics for many years to come.

A Pocket-book of Electrical Rules and Tables for the use of Electricians and Engineers. By JOHN MUNRO and ANDREW JAMIESON. London. Charles Griffin & Co., 1884.

The Electrician's Pocket-book. Being the English Edition of Hospitalier's "*Formulaire Pratique de l'Electricien.* Translated, with additions by GORDON WIGAN, M.A. Cassell & Company, Limited. London, Paris and New York, 1884.

As long ago as 1871 Messrs. Latimer Clark and Robert Sabine published their well known *Electrical Tables and Formulæ*, a work of great merit, which speedily found its way into the hands of the electricians and telegraphic engineers of both hemispheres. At that date the electrician's field of labor was comparatively a limited one, and outside of the departments of land and submarine telegraphy, can hardly be said to have had a recognized existence. It was not until a comparatively recent period that the need of a little more comprehensive work of the kind began to be seriously felt. The extensive practical application of the dynamo-electric machine in electro-plating, electric illumination, the transmission of power and even in telegraphy, has brought about an entirely different order of things from that which existed in former years. The electrician is now called upon to deal with currents of enormous volume and potential, and although it is true that these are governed by the same universal laws, the methods of dealing with them and the instruments and apparatus which it is necessary to employ for the purpose, are wholly different from those designed to cope with the comparatively feeble electric forces of an earlier day. It is not surprising, therefore, that when Messrs. Munro and Jamieson published in the summer of 1884 the first edition of their Pocket-book, the demand for it was so great that the whole edition was exhausted within a few weeks, a fact which sufficiently evidences the demand which existed for a work of the kind. The value of such a compilation as this depends very largely upon the ability and practical knowledge of the author, and in this respect it would perhaps be difficult to find two persons better qualified for the task than the gentlemen who have undertaken it.

Speaking first of externals, we find that although the whole subject of electrical engineering has been well covered and a great amount of matter collected, yet by careful condensation and skilful typography the whole has been compressed into about 500 pages, making a book similar in size and style to Molesworth's well known Engineer's Pocket-book. In fact, by reason of the small size of the page and the thinness of the paper, it is considerably less bulky than the majority of books of this class.

A work of this kind does not admit of a lengthy review, and we will therefore content ourselves by giving a synopsis of the contents, which are as follows: Units of measurement, Measures, Testing, Conductors, Dielectrics, Submarine Cables, Telegraphy, Electro-Chemistry and Metallurgy, Batteries, Dynamos and Motors, Electric Lighting, Miscellaneous and Logarithms. It will be apparent from this list of subjects that the field has been pretty well covered. The best evidence of the real value of such a work, is the opinion founded upon the experience of those who have had occasion to use it. For our own part we can say that we have kept a copy within convenient reach from the time it first came into our hands, and have come to regard it as an indispensable companion, while a number of the most prominent electrical engineers of our acquaintance have cordially endorsed our opinion of it. There is no doubt much room for criticism, for everyone has his own private opinion as to the matter which ought to be retained and that which ought to be omitted in a work of this kind, but on this point the opinion of the authors is perhaps entitled to as much respect as that of anyone else. The principal fault in the work in our opinion is the excessive amount of theoretical matter which has been included. Many of the formulæ are far to complicated to be of any practical use, and might with great advantage have been replaced with tables covering the same ground. Some of the tables too, are not sufficiently full to answer the purpose, in the refinement of modern electrical work, such for instance as the tables of logarithms. Unless these are printed with serviceable fullness, it would have been as well to have omitted them altogether.

From its intrinsic value and its convenient and attractive form the book has already met with a success which must be alike gratifying to the authors and to the publishers, and we cannot doubt that it will continue to meet with the approbation which it so well deserves.

Two editions have been published of M. Hospitalier's original *Formulaire* in the French language, and we understand that it is proposed to continue it as an annual, with such revisions and additions as may be required from year to year. The present work is an English translation based on the second edition of the original. It is hardly proper to entitle it a pocket-book, which it certainly is not in the sense in which that term is ordinarily used by working engineers. It is true it is not a very large volume, but nevertheless we fancy it would be found somewhat difficult to crowd it into the ordinary professional pocket. On the other hand it is rather too small for convenient use on the table, and moreover it is bound in such a way that it will not stay open, which in a work of this character is an exasperating inconvenience. The contents of the book are in a general sense very much the same as that of Munro and Jamieson's but the treatment is in many respects quite different. The subject matter is divided into five parts; the first comprising definitions and general laws, the second, units of measurement, the third, instruments and methods of measure-

Digitized by Google

ment, the fourth, formulæ applications and experimental results, including the production and the various applications of electricity in detail, while the fifth contains various recipes and processes. The material is very systematically arranged and a great number of tables are given. In fact, in the matter of useful tables and statistical information the work is of noteworthy value.

It is a matter of surprise to us that such a work as that of Mr. Wigan should be published without an index. This oversight greatly impairs its general usefulness. The French are incorrigible offenders in this respect, but we should have expected the translator or publisher to have supplied the omission. It is true that this is partially compensated for by the systematic arrangement of the subject-matter and an unusually full table of contents, supplemented by an index of the tables contained in the volume, but this nevertheless does not subserve the office of a topical index which enables anything required to be found in a moment, and we need hardly say that to the electrician who needs to consult a work of this kind moments are often very precious.

Were we asked to make a choice between these two collections of formulæ and tables, we should be compelled to say we would take them both, for each contains much material of value which is not to be found in the other.

Traité Pratique d'Electricité Industrielle. Par E. CADIAT and L. DUBOST. Paris: Baudry et Cie., 1885. (496 p., 204 illustrations, pr. 15 francs.)

This publication differs somewhat in character from the general run of works on electricity and its applications which have made their appearance in such numbers within the past few years. It embraces the more important industrial applications of electricity, other than the electric telegraph, and is intended rather to meet the wants of electrical constructors and practical men generally, than to enter largely into theoretical considerations, or, on the other hand, to attempt to interest the reader of what may be termed "popular-science literature." The plan of the work is excellent, and it has been carried out with intelligence and ability. The subject-matter is divided into six parts, treating respectively of the general principles of electric science, electric generators, mechanical and chemical, electric lighting, the transmission of force, electro-metallurgy and telephony.

The first part of the work presents an admirable resumé of the fundamental principles of electricity, the units of measurement and their relation to the mechanical units. The various methods of measurement of resistance, potential, current and capacity are well explained, and there are also the necessary instructions for dynamic and photometric determinations. In the second part the different forms of voltaic elements are discussed, together with the considerations upon which their relative value depends under different circumstances. There is little that is new to be found in the chapter on dynamo-electric machines, although the terse and clear manner in which the subject is presented deserves commendation. The storage battery problem is also discussed at some length. The portion of the work relating to arc and incandescent lighting is very properly confined quite closely to the systems which have thus far proved themselves efficient in practice. The results obtained by the Paris commission of 1881 are given in full. The chapter on the electric transmission of force, after having stated the nature and conditions of the problem to be solved, gives a history of the principal experiments which have been made from 1873 to the present time, especially those of Marcel Deprez. The computations of M. Beringer, giving in tabular form the comparative cost of transmitting energy to different distance by electricity, hydraulic pressure, compressed air and wire-ropes, are of much value. An interesting description is given of Fleming Jenkins' system of telpherage, which may not improbably turn out to be one of the most important inventions of the century, in the way of transportation. The chapter on electro-metallurgy though necessarily brief, is perhaps all that could be expected in a work of this kind. The concluding chapter on the telephone is simply a description of the construction and mode of operation of the existing telephone systems in France, and contains little that is new or useful to the well-informed practical electrician. In fact the subject of telephony would seem to be hardly a proper one to be included within the scope of the work.

Like most modern French scientific treatises, the book is handsomely printed and profusely illustrated with engravings, largely from original designs.

QUESTIONS AND ANSWERS.

[59.] **Correction—Dynamic Units.**—A typographical error in our last issue made nonsense of our reply to G. N. V., of Linden, N. J. What we intended to say was this :—"The unit of work is called the *erg*. It is the amount of work done by one *dyne* working through the distance of one *centimetre*, the dyne being the force which, acting upon one gramme for one second, generates a velocity of one centimetre per second.

[60.] **Electric Motor.**—L. T. W., Brooklyn, E. D., has made a motor in accordance with the directions given in the ELECTRICAL ENGINEER, and has wound it with No. 20 wire. He writes that he can get no result with four cells of Eagles' battery. **Ans.**—The Eagles battery is virtually a Daniell cell of low resistance. It is not adapted to run a motor. The resistance of the motor thus wound would probably be about four ohms, and that of the battery at least as much more, making eight ohms, while the E. M. F. will be about one volt per cell, or four volts, giving a current of about 0.5 ampères, much too small to do any work with the motor. We should recommend using No. 16 B. & S. for the field and 18 B. & S. for the armature. A bichromate battery will give the best results. Several cells will be required. The question of batteries for this motor will be taken up in due course.

[61.] **Commutator** offers valuable suggestions which will receive proper consideration. Will he kindly send his address that we may communicate with him personally?

The Competing Quotation Companies.—The War of Rates Begun.—The Spring Campaign of the Underground Raiders.—A Legislative Commission to Enforce the Law.—Closing of the Electrical and Miscellaneous Stock Exchange.—The River and Rail Electric Light Co.—A Tournament of Morse Operators.—The Pneumatic Tubes.—The Mysterious Meter.

THE war of rates between the different quotation companies was precipitated by the decision of the New York Stock Exchange to organize a bureau of its own to furnish official quotations on equal terms to all companies which would bind themselves to supply only such subscribers as the exchange considers legitimate stock-brokers. This result has been reached after long continued discussion and deliberation by the Governing Committee. It is very doubtful whether the anticipated suppression of the bucket-shops will be accomplished. If the proposed plan is actually put in practice the company which accurately prints the quotations in advance of its competitors will be rewarded by the lion's share of subscribers. Success will depend upon the speed of the instru-

Digitized by Google

ments, the perfection of the transmitter, and the skill of the transmitting operators. In this contest for the survival of the fittest there will probably be at least four entries: The Scott printer by the Gold and Stock Telegraph Co., the new Field printer by the Commercial Telegram Co., the Van Hoevenbergh printer by the Baltimore and Ohio Telegraph Co., and the Wirsching printer by the Stock Quotation Co. The two companies last named are not yet ready for business, while the two former are still using their old style of instruments. The Scott printers are finished and delivered, but it is now understood that they will not be introduced during the era of low prices.

Immediately upon learning the decision of the Stock Exchange the managers of the Gold and Stock company announced that on April 1st the rental of instruments below Chambers street would be reduced from $25 to $10 per month, which is the rate formerly established in order to crush out the Manhattan Quotation Co. 12 years ago. The stockholders of the Gold and Stock company are secured against any depreciation in the value of their holdings, as by the terms of its lease to the Western Union company a dividend of six per cent., payable quarterly, is guaranteed by the latter.

The underground wire workers have already opened the spring campaign. A special Albany despatch to the *Times* on March 10th contained the following:—

The Senate passed a humdrum day receiving bills and listening to the chunks of platitudes that dropped uninterruptedly from the lips of its members. Senator Daly introduced his bill relating to underground telegraph wires, mention of which was exclusively made in the *Times* editorial columns to-day. It provides for the appointment of a commission to carry out the Underground Telegraph Act of 1884. The commission shall devise a plan for underground wires within 60 days. The New York Commissioner of Public Works shall be *ex-officio* a member of the commission. The salary of the two commissioners shall be each $3,000 annually, and the expenses shall not exceed $10,000, the whole to be assessed on the companies.

The "exclusive" arrangement by which this underground raid is being manipulated through the columns of the *Times* is one of the peculiarities of metropolitan journalism. The Western Union Telegraph Co., and the Metropolitan Telephone and Telegraph Co., in this city, and the New York and New Jersey Telephone Co., in Brooklyn, are believed to be the only companies which are actually engaged in placing their wires underground. The Edison company, as is well known, has always used the subterranean system. It has, however, been extremely fortunate in having an apparently unlimited amount of money to invest in its plant.

On March 16th the Board of Aldermen sent to the Committee on Streets a resolution offered by Alderman Walsh revoking all permits granted to electric light companies to lay wires underground in this city except where the privileges so granted have been used. It is explained that a number of companies to which such permits have been given have never taken any steps to put their wires beneath the ground.

It is said that underground operations may be suspended during the coming summer through fear of facilitating the spread of cholera. Experts have already brought up similar objections to the proposed cable railway on account of the excavations which will necessarily be made to install it On all such questions the Board of Health in this city has arbitrary powers, and if the mortality arising from digging up the streets is likely to be any greater than that occasioned by overhead wires, which is practically *nil*, aerial lines may yet be allowed a renewed lease of life.

The Electrical, Manufacturing and Miscellaneous Stock Exchange has finally succumbed to the pressure of the times and will soon close. The enterprise was undertaken in the belief that there would be sufficient business arising from trade in electrical securities to support such an exchange and thus form a nucleus for a prosperous organization. Speculation, especially in new fields, was however paralyzed by the May panic last year, and it has been evident for some time that future success was extremely doubtful.

One of the novel projects of the day is the organization of the River and Rail Electric Light Co., of which Albon Man, of Brooklyn, is president, and whose invention evidently forms the basis of the corporation. This apparatus, which was patented March 10th, is intended to utilize the "current force of flowing waters in producing electric currents." It consists of an undershot water-wheel, mounted between two scows, arranged similarly to a catamaran. Upon one of the scows is mounted the dynamo machine, belted to the shaft of the water-wheel by the necessary number of multiplying pulleys to obtain the requisite speed. One of the objects of the invention is to provide temporary lights to place over bars and snags in western rivers. Such obstructions are liable either to appear or disappear without warning. The scows are to be anchored or secured wherever lights are required, provided, of course, that the current of the stream is sufficient to furnish the necessary power. One of the first public acts of this company was to introduce into Congress a year ago a bill "To authorize the lighting of the navigable waters of the United States with electricity." According to your Washington correspondent, writing under date of January 26, this measure has been practically killed.

Another local fast sending tournament is being organized under the management of Fred Catlin, and will take place in the lunch-room of the Western Union building on April 5. Three prizes are offered of $25, $15 and $10 each. After its termination it is believed that similar local contests will be held in different parts of the country, preliminary to a National Tournament of Morse telegraphing in this city next autumn.

The pneumatic tube system recently laid down by the Western Union Telegraph Co., between Dey and 23d street, is not proving an effectual substitute for the telegraph. The transmission through the tube, and the circumlocution at the terminals consume an average of over 20 minutes, about the time occupied by a messenger for the same distance if he travels by the elevated railway. This delay is not the worst feature however, for it is sometimes the case that a collection of messages disappears, although the carrier is not lost, as Jack Selden said when the mercury went down the sink spout, "because we know where it is." Out of 14 messages recently missing, one by one straggled along, until finally all but one was accounted for. If the paper used for message blanks was more highly finished they would not be so likely to lodge in the tube.

Electric light customers are not altogether happy under the reign of the electrical meter. The firm of Wilcox & Baird, brokers at 64 Broadway have been served by the Edison Illuminating Co. Mr. Wilcox says that the bills of the firm beginning in August were less than $5 a month, something less than gas, but that the cost increased about $1 a month. In January their bill was $8.21 and for February $8.67. A day after the last bill the moveable lamps were taken out by the firm and gas used instead of the electric light. Nevertheless, the electric light bill from Feb. 18 to March 19 was $9.29. At the office of the Edison company in Pearl street, it was stated that the bills of their customers naturally increased as the days grew shorter and vice versa. The bill of Wilcox & Baird this month was larger than last, however, although most of the other customers in the district had smaller bills. This could be accounted for on the theory only that more light than usual had been used by Wilcox & Baird. So long as the meter plates showed by decomposition that so much light had been used the company had no other alternative than to charge for it.

The Leakage Evil in Electric Lighting Circuits.—Various Interesting Electrical Experiments.—Increase in Incandescent Lighting.—The Perkins' System.—Arrival of the Lightning Arrester Vender.—A Miner's Safety Lamp.—The Latest Suggestion in Tower Lighting.

In the course of the electric light convention, recently held in this city, some of the delegates unintentionally let out the fact which has long been apparent to careful observers, that a very large proportion of all the electric light lines in the country have constantly, or nearly so, one or more ground leaks. This I hold is the great and nearly the only danger in using this wonderful force. The attempted remedy is of course a magneto call bell. These will usually, if good, ring through about 10,000 ohms resistance. Higher than that they seldom or never go, and a leak which such an instrument will not detect, may prove a very dangerous one, under peculiar circumstances which cannot be foreseen or known, until mischief has rendered it apparent. With a metallic circuit it is always the second ground which does the damage, and some method should be devised by which the first ground can be tested for daily, and that method, to be reliable, should be capable of manipulation by the party in charge of the dynamo or plant—the engineer, in a local plant, or the superintendent in a central plant. When this is done, and properly used, the hue and cry about "deadly electricity" will cease, and a huge club in the hands of the gas people and other enemies of electric lighting will have been disposed of. The newspaper reporter will have lost an item or two occasionally, but he can perhaps find some other sensation, which will not have for its butt a large and necessary industry, which despite its so-called terrors, is fast winning its way against all opposition.

Nearly every one has noticed the accumulation of minute particles of dust, lampblack, cotton shreds, etc., on the wires, particularly on arc light wires. Some experiments recently made by a French electrician clearly show this to be the result of electrical attraction. In the course of his investigations he obtained some quite interesting results in crystallizing vapors of salts, clearing a bell glass filled with smoke and the like, by a current of electricity.

A very pretty Leyden jar experiment may be made with an incandescent lamp and a rapidly moving leather belt. The capacity of the lamp for retaining the electricity is something wonderful, because of the very perfect insulation, and the rarified condition of the air within it. A Geissler tube is also a good condenser of the same sort. If into an incandescent lamp a considerable amount of current is stored, although the lamp is held in one hand, induction sparks will be given off the surface of the lamp to the fingers of the other hand, showing the high tension of the charge. I would suggest that caution be used in experimenting with these, as I know one party—no cards—who builded higher than he thought and surprised himself with his success.

During the extreme cold weather of the past two months, the amount of atmospheric electricity developed everywhere has been a source of amusement and wonder to all but the initiated. Ears have been tingled, gas lighted, etc., in nearly every house in the city, and checker boards placed on tumblers used for insulated stools, while fur wraps of all descriptions have served for exciters. I learned a few days since the reason for all this, from an elderly party in a street car, who seemed quite learned on the subject. He said this sort of thing never was known till the streets were filled with electric light wires.

A curious little experiment with frictional electricity is that in which a long, light, fibre of silk is excited by drawing it through the fingers and holding it suspended in the air. Now if the fibre, while in this excited condition is touched quickly by the finger, the polarity at that point is changed, and if several points are thus touched, one after another, the fibre will show by attraction and repulsion a series of curves and nodes in its length. Of course this can only be shown in a dry, clear atmosphere.

Incandescent lighting is on the increase with the several companies just now. The Edison folks have several of the new buildings round the new board of trade, the United States people have a lot more, and the new comer, with the Perkins lamp and the Mather dynamo has just wired, and will shortly light the Grand Opera house. This company has already one plant which is making a very pretty show of light, and giving good results. One little novelty of Perkins's invention is a table light, in which four loops are placed in multiple arc. A key at the bottom of the lamp, permits the burning of one or more of these at the same time—thus giving eight, 16, 24 or 36 candle-power in the same lamp. The breaking of one filament does not interfere, of course, with the other three, and consequently one lamp can be made to last as long as four single ones, by using one carbon at a time.

The lightning arrester fellow has been around again with an electro-magnet, which charges with the current from a battery and closing, puts on a ground, don't you see? If that gentleman will close that magnet with the discharge from a Holtz machine, or a Leyden jar, I shall take pleasure in congratulating him; but until then I must hold to the old faith, unless he can arrange to slow up an atmospheric discharge by carrying it through a wet string or some similar resistance. As an old army operator once said, "You can always tell when a mule is going to kick, if you watch his ears; but lightning hain't got no ears, and is quicker'n a mule."

A new form of safety lamp for use in mines comes from across the water. This is the invention of Mr. Coad, whose object is to prevent the spark of a breaking circuit in a lamp from igniting the gases in mines. The arrangement consists in placing the ordinary incandescent globe within another, the space between the two being filled with water and carbonic acid gas under pressure. This pressure holds the circuit closed, through the medium of a flexible disc. Breaking the lamp relieves this pressure and breaks circuit at a point thoroughly protected from contact with the air of the mine.

A daring and eminent architect of Paris, Jules Bourdais, who planned the Trocadéro Palace, according to *La Lumière Electrique*, has proposed to construct an immense tower, 360 meters high, from the top of which electric lights will shed their rays over the gay and wicked capitol. Mr. Bourdais estimates the cost of a stone and also of an iron structure, either pseudo cylindrical or a truncated cone, with a heavy base. The first is comprised of a square ornamental base, with five circular stories, each with surrounding columns and an airy look-out surmounting this, above which is a crown-like ornament and a species of pinnacle, with a statue of the genius of science, capping the whole. The lamps are to be distributed on the edge of this crown, 100 in number, of 20,000 candle-power each, or a total of 2,000,000 candle-power. Huge reflectors are to aid in the dissemination of the light. The inner portion of the column will contain 16 chambers in each section, or 80 chambers in all, of 15 square meters each, and five meters high. The look-out will accommodate 1,000 sightseers and invalids seeking pure air, while a well, 8 meters in diameter from the deck to the ground, is suggested for experimental researches in philosophy—the descent of falling bodies, compression of gases, vapors, Foucaut's pendulum, etc. It is proposed to place this grand tower near Saint Germain l'Auxerrois, lighting up the old church whose bell in 1572 rang out the knell of the Huguenots, or at Pont-Neuf. The building which forms the base of the column 66 meters high is to be utilized for the necessary steam and dynamo power.

The phalanx which stood up so solidly for tower lighting at the late convention here, must look to its laurels.

CHICAGO, March 14, 1885.

PHILADELPHIA.

Experimental Test of the Bidwell Electric Railway.—An Injunction Against Removing a Telephone.—Decline of Brotherly Love in the Quaker City.—Councils Decide to Go Slow on Electrical Questions.—Narrow Escape of a Lineman.

THE officers and stockholders of the Bidwell Electric Railway Co. gave a very interesting exhibition of their new motor a few days ago. Among the guests invited were many well-known railway men and electricians. A track had been laid around the entire room 250 feet in length, and a car capable of holding 10 persons was placed upon it. The motive power was furnished by a five h. p. dynamo. In addition to propelling the car, electricity was furnished for several incandescent lamps in the car, and for large lights along the track. The same current also heats the car.

By a novel arrangement, which is attached to the car, salt or a chemical compound can be fed to the track in cold weather to keep it clear of ice or snow, and dirt is swept out by a brush which is also attached. The experiments were perfectly successful. I understand successful tests of the system have also been made in other cities.

Charles Gibbons, Jr., a lawyer, recently filed a bill in equity against the Bell Telephone Co. to prevent the removal of his telephone. Mr. Gibbons has had a telephone in his office for over three years, under the customary contract. He paid an annual rental of $100, and the company agreed to give him "efficient telephone service," that being defined as "the best service of which the instruments and wires are reasonably capable." In October last his service became defective and for five weeks preceding February 25th he had no use of the instrument at all. When he insisted upon making a proper deduction, the company refused to allow any rebate and threatened to remove the instrument. Judge Biddle granted a preliminary injunction restraining the company and its employés from removing the telephone or interfering with its use.

Although Philadelphia is known as the city of "Brotherly Love," I am inclined to think that that endearing term is a misnomer, inasmuch as we usually have a lawsuit or two on hand in reference to electrical matters.

At a recent meeting of select council the special order was the consideration of a resolution instructing the city solicitor to begin proceedings to recover the penalty of $50 under the act of June 13, 1882, in relation to the maintenance of poles and wires for telegraph, telephone and electric light purposes in the city of Philadelphia after January 1, 1885. In calling up the special order Colonel Banes said it would be well for councils to deliberate before acting rashly in so important a matter. He had recently visited Chicago and other cities with a special view to the study of the underground system and found that in none of them had any universal system been adopted. New York had 27 miles of underground wire in successful operation, while Boston had 15,-000 feet (in sections of 3,000 feet) and Chicago 800 miles, the latter being telephone wire. There was no means of telling what would be the improvements in electricity, they were so many and so frequent. He thought it behooved councils to deliberate carefully before acting upon this resolution. They must take into consideration the rapid marches of science What seemed impossible yesterday might be easily accomplished to-morrow. He held that some portions of the main lines of telegraph might be put underground, but showed that there were certain parts of the city where poles or house wires would be absolutely essential to make connection. In conclusion he referred to the fact that the question of councils' power to tax telegraph wires was now under consideration by the Supreme Court. His motion to indefinitely postpone the consideration of the resolution prevailed.

There seems to be quite a lull in electrical matters hereabouts just at present, but as soon as the weather shows an inclination to get settled there will no doubt be a change.

Reuben A. Weeks, a lineman of the Bell Telephone Co., had two fingers of his right hand and the thumb of his left hand burned by electric wires on the 17th. He was on a pole tightening wires, and thinking it perfectly safe in daylight he caught hold of an electric light wire. The shock rendered him unconscious. He hung on until his fingers were badly burned, when he fell and was caught on a wire by the strap of his climbers. He remained suspended in the air, head down, for several minutes, until a ladder was procured and he was rescued. When brought down he was still insensible, and was taken to the hospital, where he was soon restored to consciousness. One finger was burned entirely off, and the other and the thumb were amputated.

PHILADELPHIA, March 19, 1885.

BOSTON.

Electric Street Lighting Compared with Gas and Oil.—The New Telephone Exchange.—Attempted Legislative Restriction on Telephone Rates.—Discrimination against the Baltimore & Ohio Telegraph Co.—Opposition to the Proposed Increase of the Bell Company's Capital.—Newport, R. I. Authorizes Electric Lighting.—The American Rapid Bondholders to Bring Suit for Interest.

THE annual report of the superintendent of lamps for the year 1884 has been submitted, and from it I glean the following statistics showing the comparative extent of electric lighting. The number of public lamps of all kinds in the city of Boston, Jan. 1, 1885, was as follows:

Digitized by Google

Gas Lamps	9,781
Large gas lamps	36
Oil lamps	2,591
Electric lamps	401
Total	12,809

The total cost of gas lighting	$255,463.30
" " oil lighting	5,565.93
" " electric lighting	90,785.80
Total	$351,815.03

The relative total cost of the different systems per lamp was—

Small gas lamps 4 feet each per year	$ 31.85
Large " 30 " "	$121.22 to 180.31
Oil lamps, each per year	13.78
Electric lamps, each per year	226.40

The large gas lamps are in use in public places, but some of them do not burn all night.

The introduction of electric lights in this city for street lighting dates from February 15, 1882, beginning with five lights in Scollay square, which had been previously lighted by the Brush Electric Light Co. as an experiment. According to the report of the department there were in use

January 1, 1883	114 lights
" 1, 1884	381 "
" 1, 1885	401 "

These lights are distributed as follows :—

Brush—	City proper	178	
	Roxbury	40	
			218
New England Weston—	City	54	
	South Boston	63	
	Charlestown	24	
			141
Merchants—	Boston Common	3	
	Public Garden	18	
	Back Bay	5	
			26
Union			16
			401

The electric light competition has forced the price of gas down during the year. New contracts were made with seven of the gas companies furnishing gas to the city and annexed suburbs last May, the prices ranging from $1.75 to $2.00 per 1,000 ft. The public lamps are burned every night throughout the year, a total of 3,828 hours each. In 1879 the automatic glycerine burner was adopted, and has continued to give good satisfaction, and to accomplish all that is claimed for it. The lanterns are of tinned copper, and are so constructed that the names and numbers of streets may be placed in them.

Colored glass is used for name and number signs—the letters and figures being made by the sand blast process. Nearly one-half of the gas lamps stand on the corners of streets ; and where they have been displaced by electric lights, the removal of the street names and numbers has caused great inconvenience and complaint.

The large three-cluster burner "Bray" lanterns in use give good satisfaction ; they cost $40 complete. In addition to these 30 feet burners, the demand for more light has caused the introduction of many five and nine feet burners. The entire cost of the lamp department for the municipal year was $491,654.31.

The multiple system as manufactured by the Western Electric Co., largely under Scribner's patents, was inaugurated at the new Boston telephone exchange, 50 Pearl street, on the 22d of February—supplanting the Gilliland switch-boards. To introduce this and to change systems and offices without interfering with business has required a vast amount of work, thought and time. As extra attention is to be given to out-of-town talking all of those lines are separate from the exchange room. The change necessitated different numbers, and new lists of subscribers. At one o'clock on the 22d the wires were removed from the old building to the new. It has been a trying and perplexing thing to arrange all of the details and it is to be hoped that it will work enough better to pay for the trouble and expense. Great credit is due to Mr. John J. Carty for the success that has attended the improvement. The calls were somewhat irregular for a few days, the school house being new the girls did not get the hang of it at first, but its all right now. The operating room is first-class in every respect, one important advantage being the clear strong north light which they enjoy.

At the State house, on Feb. 18, the committee on mercantile affairs gave a hearing upon the petition of Lowell parties for a restriction on the rates charged by the American Bell Telephone Co. The case was opened by Parker C. Chandler, who argued that telephone companies should be obliged to make connections with all telegraph companies. He complained that the Baltimore & Ohio Telegraph Co. was not permitted to have telephone connection with the Bell company's system, and read numerous legal decisions to support the point that in the Western States the leaning of the courts has been in the direction of greater freedom, and of the doctrine that a telephone company is a common carrier. H. C. Bolles, agent of the B. & O. at New Bedford, testified of the refusal of the Bell company to permit his company to have a telephone connection. H. W. Kilbourne, superintendent of the Boston District Telegraph Co., stated that the Bell company had refused his request for a telephone, though it would be willing to provide such connection if its contract with the Western Union permitted. The District company is in the service of the B. & O. and the Commercial Cable Co. A. G. Ryder, agent of the B. & O. at Taunton, testified to the same effect as Mr. Bolles. O. L. Barron, the B. & O. agent at Gloucester, said he had a telephone in his office, and used it, but was not supposed to. Mayor Donovan, of Lowell, stated that the B. & O. in Lowell, had been refused telephone connection.

On the 26th, the Western Union side was presented by Geo. S. Hale. He seemed to think his case was prejudiced, as he had been informed the W. U. T. Co. was regarded as a monopoly, the property of Jay Gould, etc. To combat such groundless ideas he showed that 33,428 shares of W. U. are held by 410 residents of Massachusetts, and that in 10 years the company has paid above $100,000 in taxes, while the B. & O., which is at the bottom of the present attack, has but $10,000 capital in the state, held in 100 shares, while but 40 places in New England are reached by its lines. He claimed that the W. U. had a right to make any contract it pleased with the American Bell company. He proposed an amendment to the bill under consideration, which was a proviso that no existing contracts should be abrogated. P. C. Chandler submitted a shorter draft of his bill requiring the Bell company to admit all telegraph companies to its facilities on equal terms. He claimed that patents are subject to police regulation in the several states, and convey exclusive rights to individuals only to the extent that any rights at all are permitted.

On March 4th, the committee on mercantile affairs began to hear the petition of the Bell Telephone Co. for an alteration of its charter so as to allow an increase of its capital stock, also to hear parties relative to placing telephone companies under state supervision. Hon. Geo. A. Bruce opened for the Bell company with a general history of the telephone, and stated what the company desired to do with the increased capital, it being principally their desire to enter into the long distance telephone business. Wm. H. Forbes, president of the Bell company, dilated upon the desirability of long distance telephone lines, and purchase of patents for such business, and corroborated Mr. Bruce's statements. Mr. Edward Atkinson stated that long distance telephony would be of great benefit to manufacturers, and recommended the increase of capital stock asked for. Col. Jonas H. French stated he was in the Senate when the present capital was asked for and thought $15,000,000 too much, but now thinks that $30,000,000 will prove too little rather than too much ; and urged the desirability of keeping the corporation in Massachusetts. He did not think there was any justice in regulating telephone charges by legislation. The matter should be left to supply and demand, the present rates not being extravagant for the service rendered.

A petition, stated to have been signed by 4,500 business men and others, to be presented to the legislature, "that charges for telephone service may be reduced and limited by law in this state" —has been one of the features of the month of February. All persons in sympathy are requested to send their names to the "Telephone Subscribers' Union," P. O. box 2,734, Boston. It is very desirable to have telephones cheap, but I wonder if these parties would approve of petitions being presented to the legislature to have prices fixed for groceries, hides, leather, etc.? Perhaps the whole affair is to offset the anticipated advance in telephone rates.

On the 10th, the committee listened to further testimony relating to the reduction of charges. The opposition to the Bell company comes largely from Lowell, where a great proportion of the stock of the New England Telephone Co. is held. These parties paid good prices for their stock originally and when the consolidation of the several New England companies was effected and the American Bell company obtained 50 per cent. of the consolidated stock, the original stockholders found themselves divided by two. The legislature will probably not interfere in the matter.

Newport, R. I., is still without a contract for the lighting of its streets. After the practical abandonment of the electric light the force of public opinion led to a consideration of its merits. Detailed proposals have been made by several electric light companies for the street service, and the gas and lamp committee sent over two hundred letters of inquiry to as many cities and towns using the electric light. A resolve to use the Thomson-Houston system has been defeated, but the general cause of electric lighting has triumphed, and the citizens and summer visitors will have something more than the light of the moon to see their way home by—though the moon may wane, the electric light will shine.

A complaint has been filed by Arthur D. Payne, of Providence,

R. I., in the clerk's office of the United States circuit court against the American Rapid Telegraph Co. of Connecticut, *et al.* This bill is in the interest of holders of interest coupons of the first mortgage bonds of the company in Connecticut and in other states for failure to pay the interest on the coupons. A receiver is asked for, pending the suit. The bill is returnable April 6.

BOSTON, March 17, 1885.

NEW ORLEANS.

An Improvement in the Financial Outlook.—Exhibits of Maryland, Pennsylvania and New Jersey.—The Crescent City Dependent upon Electricity pending the Gas War.—Flourishing Condition of the Local Brush Company.—Street Lamps Borrowed for Household Use.—Successful Bidders for City Lighting.—Telephone and Time Telegraph Affairs.

SINCE the dawn of clearer skies on the passage of the loan bill by Congress, the electric light people of the exposition wear more cheerful faces. The prospects are that they will certainly get paid for all work done during the past three months, but whether or no they will be as successful for the balance of the term remains to be seen. Owing to the fact that all bills due to parties outside of Louisiana taking precedence, the Edison, Jenney and Thomson-Houston companies may fare better in the distribution of the $350,000, than the Louisiana and Brush, both of which are home institutions. In the financial statement rendered to Congress by director-general Burke, over $30,000 were entered as due the lighting companies. The Edison lamps in the government building have not yet been lighted, and now it begins to look as though they never would be. The dynamos are ready, and the offices wired, but the motive power is lacking, therefore it would seem that the company is not to blame. The Art gallery was lighted on the 14th for the first time.

The Baltimore and Ohio R. R. Co. makes quite an electric display among the Maryland state exhibits. A model of the original patented Morse telegraph instrument has by its side one of the Selden sextuplex system, the company owning the patents covering the latter. A Page motor is shown, represented to be a model of the first electrical invention ever used to propel a railroad car, making its trial trip over this road in 1851. Here is also the original first telegram ever transmitted, as mentioned in a previous letter.

In the Pennsylvania department, and displayed by Partrick and Carter of Philadelphia, is a case of telegraph instruments, switches, etc., with vulcanized-fibre bases and trimmings; also samples of the fibre itself. Many passers-by are startled in the New Jersey aisle, by the sudden ringing of an electric bell; inquiry developing the fact of its being caused by their own footsteps on an Applegate electric mat, not observed, as it is covered by an ordinary rug. This must prove a desirable burglar alarm in warm climates, where for a greater portion of the year doors and windows must be left open all night.

Our many visitors have lately had an opportunity to see how our city fathers run things in this town—and no tax is levied upon them for taking items to be used in improving their own governments when they reach home. Nearly every year the gas company has a falling out with the council and shuts the gas off from all street lamps, until they come to terms. This is now the "accepted time" and for ten nights the streets—save the few which enjoy the electric lights—have been as dark as Erebus. It seems that the great number of electric lamps put up within the past year have displaced very many gaslights, and still the gas company insisted upon burning them and charging therefor. Recently, however, the contract expired, and it is now the number of lamps to be contracted for upon which the trouble hinges.

Heretofore the local Brush company has had a clear field and it has improved its opportunities. It was organized in 1881 and on February 1st, 1882, steam was turned on for the first time. Eighty lights was then the capacity of the plant, 40 of which were lighted that evening. Success characterized every effort and business increased steadily until to-day when there are over 700 lamps in use. Five miles of the city front on the river are furnished with 100 lamps. An iron tower 175 feet in height and carrying six lamps was erected by the company, to show what it could do in that line. This it was hoped would lead to adoption of that system for the rear of the city, a section some eight miles long by over a half mile wide, and perhaps it will, but by another company. Among the exposition light people, I have heard it said upon all sides that the New Orleans company or rather the South-western Brush Co., has the finest Brush plant and lamps to be found anywhere. By a recent change of the armatures, old 40-light machines have been increased in capacity to 65 lamps: 15 of these dynamos are now running, being driven by three Atlas-Corliss engines. A portion of this city is not blessed with gas mains, the streets as well as buildings being lighted by oil. Some time since, several of the residents of this suburban or "oil district" as it is called, appealed to the council for electric lights, saying that some of the more enterprising citizens were in the habit of borrowing the street lamps at night, returning them empty in the morning! In the meantime the streets were in darkness. Perhaps the trouble was caused by there not being enough lamps to go round, who knows? This state of affairs struck the council as not being just the thing, so they advertised for bids, and after some delay, accepted by a large majority that of the Louisiana Electric Light and Power Co. This called for about 300 lamps—20 towers carrying six each at $1,200 per year, and the balance on poles at $146, per year. This contract now awaits the Mayor's signature, but in the meantime the Brush company have offered lower figures, so it remains to be seen what will be the result. The Louisiana company proposes to use the star tower and Jenney system upon all city contracts it may make, but for other purposes the Excelsior machines and Muller lamps will be adhered to. When the exposition is over, they will bring down their large plant and compete for a share of the private lighting of the city.

Telephones seem to be still in demand. The great Southern company has finished the copper wire line to Baton Rouge, and it is working splendidly. A steel wire of same size, No, 14 has been put up to Terre Haute, a distance of 28 miles. These two lines must prove a boon to the people along the routes, as heretofore they have had no direct communication with the outside world. The branch exchange at the exposition has proved a successful venture and will net a handsome profit. The time service is meeting with favor, 248 clocks are out, and the prospects good for the number soon to be increased to 300. Sixty have been placed in the government building as an exhibit. One in the office of the writer keeps accurate time, and has become an "institution."

The Crescent City Telephone Co's poles are going up on our principal streets, and the stringing of wires commenced. The advantage of having two companies will soon be discovered, that is if any exists.

NEW ORLEANS, March, 15, 1885.

SAN FRANCISCO.

The Coming Opposition Telegraph System.—Telephones and Electric Lights in the Extreme North-west Where Some of the Old-Timers are Located.—The Rival District Companies.

I CAN now state on reliable authority that operations will begin on the construction of a new opposition telegraph on this coast almost immediately. The recent railroad developments, and the peculiar manipulations of Senator Stanford would lead an ordinary thinker to believe that it looked as if he meant "to go the whole hand alone," and it would not be surprising if the Western Union at an early date received the stipulated "six months notice" of a desire to break the contract now existing between them. If this will culminate, as events forebode it will, then with Mr. Crocker's friendship and implicit reliance on James Gamble, do not be surprised to see Mackay, Bennett, Bates, Stanford & Co., a powerful rival to Jay Gould and his connections.

A system of interlocking railroad switches controlled by electricity is being introduced at Oakland. Will Slater is to have charge of the system.

The telephones on the Columbia River and Puget Sound are as successfully operated as in California. In Portland and East Portland there are 400 telephones in connection with the main exchange, and about 90 Brush lamps are lighted. These are under the management of J. H. Thatcher, who in the palmy days of the Comstock used to send cipher messages at the rate of 80 an hour to William Foley. In Seattle there are about 170 telephones and all the saw-mills on the Sound are lighted by electricity. Geo. D. Snow is general overseer. Tacoma too, has a thriving exchange, and our staid neighbors in British Columbia are not behind-hand. F. H. Lamb who with Frank Drummond and Charlie Moore, learned self-denial in Libby prison in '62, is superintendent of telegraph, with headquarters at Portland. John Henderson, ex-manager of Salt Lake, is also in Portland. J. W. Hayes is manager of the Portland office and assists Mr. Lamb in some of his outside duties.

The rivalry that exists between the San Francisco District and the American District companies is very peculiar. Every week one company makes the other a present of a large number of its own boxes. A few days ago, 160 boxes taken out by order of various subscribers and supplanted by San Francisco District boxes, were sent to the American District, the compliment was returned with interest later, and still the war goes on. It is said Mr. Gill of the San Francisco company is in negotiation with Mr. Gamble to do the city delivery for his company when it reaches here, in the same manner as the American District do it for the Western Union.

WASHINGTON.

Arc Lamps at the White House Entrance.—Establishment of Police Patrol Stations.—The Telephone Wires Going Underground Rapidly.—Telegraph Instruments Removed Without Authority.—Telegraphers' Mutual Relief Association.—Important Decision in Incandescent Lamp Patents.

To assist in giving *eclat* to the occasion of the inauguration of President Cleveland, the United States Electric Light Co., at con-

Digitized by Google

siderable expense, put up eight of their arc lights in front of the executive mansion, four directly in front of the main entrance, one at each gateway, and one midway on each of the circular roadways leading from the gates to the mansion. In order that the work might be first-class, the wires were laid in underground cables and led up through the posts so as to be entirely invisible. The effect was excellent, and gave so good satisfaction that an order has been given for a continuance of the lighting, in place of the gas lamps by which the approaches to the mansion have heretofore been lighted. The incandescent lights for the Interior department, mentioned in a former letter, have been put in by this company, and give much satisfaction; they are used in the sub-basement—which is never penetrated by day-light—amongst a mass of papers piled up as closely as is possible, and at the same time reserve access to them. The danger of fire, by the flame from the gas burners blowing against the inflammable files is by the substitution of the electric light avoided, a precaution not to be lightly estimated in a building of this character, especially after the experience of a few years ago.

Owing to the unusually crowded condition of the streets, at this time, and the severe weather, the United States company has not yet laid the underground wires for lighting Ninth street but expects to now put in the wires and light the street at once. The company seems to be well established, and doing a good business, at reasonably remunerative rates. A day circuit has recently been started for the convenience of business houses, in lighting basements, dark passages, etc. Sufficient patronage has been secured to warrant its continuance.

The district authorities have taken another forward step, and had the Gamewell system of patrol stations put in the fifth precinct, making two of the eight police precincts that are now supplied with these stations. Their use in the seventh precinct where they have been on trial for a year or more, has been very satisfactory, and the commissioners would have them put up in all parts of the district, but for want of funds that can be applied to that purpose. Unless sanctioned otherwise by Congress the work will have to be done precinct by precinct each year until the whole is done. The cost of the 30 stations already put in is about $7,600. Some of the larger and less densely populated precincts may cost a trifle above the average.

For the past 12 months the Chesapeake and Potomac Telephone Co. has been engaged in making a permanent plant of what was the merest temporary structure. To a great extent the badly insulated, and illy secured air lines have been replaced with underground cables until there are now over 10,000 miles of conducting wires underground. Most of this work has been done in Washington, and it is proposed to follow it up with a further outlay of $30,000 during the coming summer. To accomplish this it has been necessary to pass dividends for some time past, but those interested seem perfectly satisfied with this disposition of the earnings. The earnings of the company in 1884 were 33 per cent. more than those of the preceding year.

One day last week some scoundrel, on mischief bent, entered the lobby in the rear of the reporter's gallery in the Senate, and amused himself by tearing out the telegraph instruments of the Baltimore & Ohio company and the instruments of the United Press on the opposite side of the lobby. Who the miscreant was, or what was his motive is a mystery. The suggestion that it might have been some dissatisfied operator is discarded because of the wires of the United Press having suffered, as that organization stands high universally with the craft. It was probably the freak of a drunken outsider, for the manner in which the work was done shows a want of knowledge of telegraph matters. It was fortunate for the Pennsylvania troops that they had gone home or it would certainly have been charged to them.

Owing to the hurry and bustle incident to the last days of Congress the necessary order was not given for lighting the Senate chamber, corridors and committee rooms, much to the regret of many senators and employés, to say nothing of the parties interested in the introduction of the light. As the extra session is only for the transaction of executive business the order cannot be given until Congress re-assembles in December. It will doubtless then be given for the cloak-rooms, corridors, committee-rooms, etc., omitting perhaps the lighting of the ceiling over the chamber, from whence the impure air is carried by fans out through the roof and does not reach the chamber or any part of the building.

The Telegraphers' Mutual Relief Association of this city, recently held its third annual meeting. The old officers, D. Marean, president, James B. Austin, secretary, and J. H. King, treasurer, with the old executive committee, were re-elected. The treasurer reported $385 on hand and $145 paid out in sick benefits during the year, making a total of $458 benefits in three years. The dues in this association are but 50 cents per month and seven dollars a week are paid whenever a member is prevented by sickness from attending to his ordinary business.

All the telegraph offices in the city were over-crowded with matter during Inauguration week, but they generally managed to get off their business. It was too much to expect of the average messenger boy that he would hurry out with his messages and return promptly with the troops parading the streets in all directions, presenting to his boyish vision probably the greatest military spectacle of his life. The offices put out placards "Boys Wanted" but the American urchin was not disposed to lose the show for a day or two of employment, and the messages had to wait till "Young America" was ready to deliver them.

It is rumored that the interference in the patent office, which has been in progress for several years, between Sawyer & Man and Edison, involving the question of priority of invention of an incandescent lamp filament made of carbonized fibre, has been finally decided in favor of Sawyer and Man. This is likely to have an important bearing on the future control of the incandescent lighting business in this country.

WASHINGTON, March 23, 1885.

ELECTRICAL NEWS AND NOTES.

THE TELEPHONE INTERFERENCE.—DECISION OF THE COMMISSIONER OF PATENTS.

CASES A AND B. VOELKER *v.* GRAY *v.* EDISON *v.* BELL. CASE G. EDISON *v.* GRAY *v.* MCDONOUGH *v.* BELL. CASE NO. 1. VOELKER *v.* EDISON *v.* IRWIN.

Decided March 3, 1885.

1. When an applicant seeks to overthrow a patent granted to one who, though junior in date of conception, has yet shown diligence in filing his application and reducing his invention to practice, the former must show entire freedom from laches; and doubts should be resolved in favor of the patentee.
2. It is not enough for a party to show that he was experimenting in the direction of the invention, but he must have matured his conception so that it can be materialized into an operative device. The conception which the law recognizes is not that of the result to be attained, but that of the means to produce such result.
3. The specification of an application for an alleged pioneer invention is addressed to those skilled in the art as it existed before the making of the particular invention therein referred to, and is not to be supplemented and aided by knowledge of events transpiring at a subsequent period, or derived from another's invention of the same thing.
4. An occasional accidental operation of a device, varying from its usual operation, and which is at war with the principle upon which it was designed to act, is not a sound basis for a claim as an inventor to a device capable of uniformly producing similar effects.
5. The declaration of an interference is made on the assumption that the application or patent put in interference covers an operative device, but it by no means follows that such presumption is conclusive; the question of operativeness may be raised and considered in determining the question of priority.
6. The controlling issue in this contest is, in howsoever many claims or subordinate issues it may find expression, a speaking telephone. The inventor of an art and apparatus for transmitting articulate speech cannot be defeated or put under tribute by those who claim to have invented certain constituent elements, but who certainly never produced the completed invention—a speaking telephone.
7. Bell is adjudged the prior inventor of all the issues save D and No. 1, and upon these latter two, priority is awarded to Edison.

THE SPEAKING TELEPHONE.

APPEAL from the Examiners-in-Chief.

Cases A and B.—Application of W. L. Voelker, filed May 19, 1879. Application No. 1, of Elisha Gray, filed October 29, 1877. Application No. 130, of T. A. Edison, filed April 27, 1877. Patent No. 174,465, dated March 7, 1876, of A. G. Bell.

Case G.—Application No. 48, of T. A. Edison, filed December 24, 1877. Application No. 3, of Elisha Gray, filed October 29, 1877. Application of J. W. McDonough, filed April 10, 1876. Patent No. 174,465, dated March 7, 1876, of A. G. Bell.

Case No. 1.—Application of W. L. Voelker, filed September 26, 1879. Application No. 141, of T. A. Edison, filed July 20, 1877. Application of J. H. Irwin, filed May 24, 1879.

Mr. G. W. Dyer, for Voelker.
Messrs. Baldwin, Hopkins & Peyton, for Gray.
Mr. L. W. Serrell and *Hon. Roscoe Conkling*, for Edison.
Mr. J. J. Storrow and *Mr. Chauncey Smith*, for Bell.
Mr. W. W. Hicks and *Mr. S. A. Duncan*, for McDonough.
Mr. G. W. Dyer, for Irwin.

BUTTERWORTH, *Commissioner:*

The hearing of this case before the Examiner of Interferences was in the latter part of 1882. He held the case under advisement about eighteen months. His decision is very full and reviews the law and evidence with great elaboration and care. The printed decision makes a volume of over three hundred pages. Every fact and phase of the case were carefully and critically considered, and every conclusion written out. The decision was in favor of Bell on all the issues except D, No. 1, and G. In issue G, priority was awarded to McDonough. In issues D and No. 1, Edison was adjudged to be the prior inventor. From the decision of the Examiner of Interferences an appeal was prosecuted to the Examiners-in-Chief in cases A, B, C, E, G, J, L, and No. 1. No appeal was taken in cases D, F, and I. The case was again fully argued, held under advisement several months, and a very full opinion rendered by the Examiners-in-Chief in October last. The action of the Examiner of Interferences was affirmed, except as to issue G, in which priority was awarded to Bell. From this decision the case was appealed to the Commissioner, and seven

Digitized by Google

days devoted to the hearing. Some additional testimony given by Professors Young and Brackett, and considered in the argument, is before me.

Counsel are thoroughly familiar with every fact disclosed by the record which is important to any one of the issues; nothing which has any important bearing on the case has escaped consideration in the argument. In the course of the several hearings all that savors of husk and chaff has been cleared away, and the important controlling evidence, with the exhibits, drawings, and models, presented.

The time I have at my disposal to devote to the preparation of a decision precludes me from reviewing in an elaborate opinion the several points considered. I had proposed to do this, and had arranged notes of evidence and decisions accordingly; but I find that the time within which the decision must be signed is too brief to enable me to properly perform that work. If on examination of the evidence and consideration of the arguments I had become convinced that the findings and decision of the Examiners-in-Chief were erroneous, or if a serious doubt in that behalf had been raised in my mind, I would have felt constrained to leave the case undecided to be reheard by my successor. Had I reached a different conclusion, it would have been desirable that the reasons for overruling the decision of the board should be stated at length.

In reaching a right decision in a case like this, where the interests involved are great, as well as the honor of inventing an instrument so wonderful in its character and uses as the telephone, certain probabilities which always inhere in ascertained facts and conditions must inevitably have great influence. As a guide to truth it is safer to rely upon the actions of men than upon their expressed declarations, where the actions and declarations are inconsistent. Individuals, as a rule, act and speak in harmony with their own interests, certainly if consistent with truth. All persons reason in the direction of their desires, and resolve doubts in their own favor. When the dim and distant recollection of a party concerning his own or the conduct of another, in a matter of great interest to him who speaks, is found to be wholly at variance with what the known facts in that connection would naturally suggest and prompt, the fair inference is that the recollection of the witness is at fault, and that the logic of the known facts points nearer to the truth. It is natural for persons to hunt hastily through the pigeon-holes of memory, where unpleasant or damaging truths are supposed to be stored away; and, on the other hand, it is just as natural to encourage and quicken the pace of a lagging and uncertain recollection which is believed to contain even a fragmentary fact which will tend to mend a flaw in a title through which valuable interests may escape.

When an applicant seeks to overthrow a patent granted to one who, though junior in date of conception, has yet shown diligence in filing his application and reducing his invention to practice, the former must, in view of the importance, not merely to the patentee but to the general public, show entire freedom from laches. Nothing could sooner bring the patent system into disfavor than to permit a patent granted for a valuable invention in which thousands have become interested to be overthrown by a competitor in the same field of invention on evidence which fails fully to establish the superior claims of the junior applicant to be adjudged the prior inventor. And it is in view of this fact that doubts are resolved in favor of the patentee. See *Cushman* v. *Parham*, C. D., 1876, 130; *Wheeler* v. *Chenoweth*, C. D., 1869, 43; *McKnight* v. *Van Wagenen*, C. D., 1876, 127; *Richardson* v. *Denza*, C. D., 1870, 156; *Morse* v. *Clark*, C. D., 1872, 58; *Gray* v. *Hall*, C. D., 1871. 129; *Busha* v. *Phelps*, C. D., 1876, 119; *Wheeler* v. *Clipper Mower and Reaper Co.*, 6 Fisher, 1: *Stoner* v. *Clark*, C. D., 1877, 92; *Towers* v. *Pease*, C. D., 1878, 6; *Sargent* v. *Burge*, C. D., 1877, 62. And also the following court decisions: *Ellithorpe* v. *Robertson* (2 Fisher, 83;) *Union Sugar Refinery* v. *Matthessen* (2 Fisher, 62).

To defeat a patent it is not enough for an applicant to show that he was experimenting in the same field of investigation, and that his experiments finally led up to the invention in controversy. He must have been first to conceive *the thing* in controversy; not merely to have *conceived it possible to construct a device* which would produce the result sought. In the case under consideration it was not enough for any one of the parties engaged in the interference with Bell's patent to show that he conceived that an apparatus could be so constructed as to transmit articulate speech by the utilization of an electric current. Such an idea was not new, nor does it occur that apparatuses were wanting which were constructed for that purpose and which would transmit or reproduce sounds. The thing for which the commercial and scientific world was waiting was a method and apparatus for transmitting articulate speech in such manner as to preserve what the scientists and counsel term "*quality*," by which is meant that characteristic of sound which enables us to distinguish two sounds which have the same pitch and the same intensity from each other. It is the quality of sound which enables us to distinguish the voice of one individual from that of another. It is not enough that an applicant ranging through the field of experiment unconsciously stumbles upon that which is nearly related and very similar to the device in controversy. The conception must not be of the result to be attained, but the means (which is the patentable thing) to produce that result. As long as there was a missing ingredient, in the absence of which the means utilized was a failure and the desired result unattainable, the invention was incomplete. The question is, what was in fact accomplished, *not what could have been* had the inventor possessed the light which he subsequently obtained, either by research or from a more successful competitor. There is not unfrequently a disposition on the part of an applicant to confound a strong desire in the mind to produce certain results by some means of which he has but a vague and indefinite conception with an intelligent conception of a machine adapted to accomplish those results. It is in such cases that the desire, coupled with the imperfect conception of a device, ripens and matures in the light of subsequent knowledge. That of which the law takes notice is not the maturing, but the matured conception, which can materialize in an operative device; but it very frequently occurs that the inventor confounds his original desire and later conception and gives the latter the date of the former, and does it innocently. In such cases we appeal to the inherent probabilities, which are always the ear-marks of truth. One is found in the conduct of men - for instance, where a person has been searching long and earnestly for a valuable thing which he is anxious to utilize, and can only utilize when found by introducing it to the public. If the searcher is successful and develops the valuable thing sought, he is not likely to conceal it. He does not put it aside and out of sight for years, but he at once takes it to the waiting public. In other words, he acts reasonably and in accordance with what the experience and observation of men teach us is natural and logical under the circumstances.

It occurs in this case that Voelker in his search discovered what had been known to the scientific world for fifteen or twenty years. It was not what the public demanded and was waiting for. It has no value, even as a scientific toy. After Bell had invented and successfully introduced his speaking telephone Voelker unpacked his trunk and brought out the device mentioned, and in the light of what Bell had taught the world concluded that he (Voelker) had been ahead of Bell in producing a speaking-telephone, though unaware of the fact. True, his models did not and could not talk when he wanted them to talk, and when for the purposes of the public and of this case they should have talked; but, as stated, since the advent of Bell's telephone it is urged that the Voelker device, as he constructed it in 1877, and stored it away, has during its retirement become loquacious. The same may be said of McDonough's invention. It was no substantial improvement on Reis's. Whatever defects McDonough considered to exist in the Reis instrument, he did not regard the palpable make-and-break element to be one, since he provides in his best model, not for the imperceptible make-and-break of which Professors Young and Brackett speak in their evidence taken in the case of the *American Bell Telephone Company* v. *The Overland Telephone Company of New Jersey*, and which can hardly be regarded as coming within the definition of what McDonough requires and provides for in his telephone, but a palpable make-and-break of the current.

The circuit-breaker mentioned and described in the specification of McDonough and shown in his drawings is treated by his able counsel as a mere adjuster, peculiarly adapted to the purpose of so regulating the current as to attain the best results—whether that was to keep the circuit closed, to make the theoretical make-and-break of Professors Young and Brackett, or the palpable, perceptible make-and-break of McDonough. In this model of McDonough the learned counsel finds all the elements required, and in proper combination and perfect adaptation to the use called for in issue G; for, says counsel, if it be true, as claimed, that McDonough's *theory* required a make-and-break system in which the makes and breaks should be palpable, yet if he did, nevertheless, in fact produce a device that supplied not only the conditions of a make-and-break system, but also of the closed-circuit system of Bell, having produced the *thing* sought, it is not important that his theory was unsound, since he was not required to have any theory about it. What the public wanted, what the commercial world would buy and pay for, was an instrument that would produce the results sought without reference to or concern about the theory or reasoning of the inventor, since he may have given the world a useful invention, and yet have held a very erroneous theory in regard to its scientific operation.

General Duncan says the true and only lawful test to apply to the McDonough specification is to determine whether the description is such as to enable a person skilled in the art to make a speaking-telephone. In this connection it must be supposed that the McDonough specifications were addressed to those skilled in the art as it existed before the invention of the speaking-telephone. The speaking-telephone was what McDonough was trying to invent, and his apparatus reflected his best conception of that art and the means to practice it; and Bell's specification indicated his conception of the art and the means adopted to practice. There were at that date none skilled in the art as it is now understood, and the most and best an electrician at that time

could do would be to intelligently follow the specification contained in the application. In following the McDonough specification the Reis instrument would be produced, while an intelligent construction in accordance with the Bell specification would, as it did, produce a speaking-telephone. As an abstract proposition, I agree that General Duncan is correct; but his reasoning, when applied to the facts in this case, is more ingenious than sound. That the circuit-breaker used by McDonough was intended to perform just the office its name implies cannot be seriously questioned. That it was not a mere adjuster to regulate the flow of the current so as to vary it between full force and zero, with an occasional range to the latter, which I understand to be the make-and-break contemplated by Professors Young and Brackett, is utterly improbable. That it was intended to preserve contact, and so maintain a closed circuit, is unreasonable. Nothing in the name of the device (and the name clearly points out its function) suggests such a thing. Nothing said in the specification in regard to it is at war with the function ascribed to it by the name by which it is designated. It occurs in this case that that which counsel referred to as a mere theory or philosophical disquisition of McDonough is of controlling importance, because he either conceived a speaking-telephone within the terms of the issue or he did not. There is no pretense that he did not make his model in accordance with his conception (else his model would not illustrate his invention), nor that his conception was not the result of and the mere reflection of his theory. His theory was that a talking-telephone involved, as an indispensable element, a make and-break system (not the theoretical make-and-break of Professors Young and Brackett, but that which is palpable, perceptible). His conception of his invention responded to that theory, and his model was the materialization of that conception. His drawing and specification were in harmony with all three. So the circuit-breaker of McDonough's application is a key to the line of his investigation and the theory resulting from it. It indicates the source of his conception and the precise character of the invention upon which he predicates his claim to priority over Bell in this interference.

I recur again for a moment to the points before mentioned—to wit, that it is of no consequence what *theory* McDonough held if he in fact produced an invention which met the requirements of a speaking-telephone within the terms of the issue. Counsel proceeded to assert that McDonough did invent and construct a speaking-telephone, and that his models show it, and he refers to the evidence relied on to sustain his assertions. If McDonough, in the course of his experiments, did occasionally hear spoken words, was it because the instrument was made in accordance with his conception, as reflected in his application, drawing, and model, or because of an accidental condition not mentioned or demanded by the terms of his application? If a machine operating upon a different principle, and not in conformity to McDonough's conception, and at war with his theory, did occasionally talk, as asserted, it is clear that McDonough could not justly claim that such result was due to his theory, conception, or mechanical construction; and the cases cited by the learned counsel are in point, for in each of those cases the point is distinctly made that mere accidental use by a person is not conscious invention. He does not know that he has invented anything, and hence cannot know that he has anything to offer to others. *Colgate* v. *West. Un. Tel. Co.*, 15 Blatchf., 365; *Tilghman* v. *Proctor*, 102 U. S., 707.

Counsel says that it is not competent to hold that the McDonough device did not talk because it could not, and the Examiners-in-Chief erred in so doing, since that assumes the inoperativeness of a device upon which the Office has already passed. It will be observed, however, that the learned counsel argues with equal force that the device covered by the Bell patent is not an operative device, because it could not talk if constructed according to Bell's specification; and he says further, if Bell had died leaving to the world no other information touching a telephone than is contained in his application upon which his patent is predicated the public would never have heard of the Bell telephone, nor of Bell himself. The argument is legitimate, although the conclusion may be unauthorized.

The declaration of an interference is made on the assumption that the application or patent put in interference covers an operative device; but it by no means follows that such presumption is conclusive. It would border on the absurd to say that the moment the consideration of a vital question, important to both parties, and concerning that about which each has a right to be heard, is approached the hearing shall stop, and as to that important question the case should proceed *ex parte*. A motion to dissolve the interference is suggested as a proper proceeding, if the question of the operativeness of the device is raised in any manner or at any time. There is no reason why the question should not be raised and considered in determining that of priority. If the device of one of the parties is found to be inoperative, a dissolution of the interference would follow; at least the party having such device would have judgment against him.

It being competent to consider, as an item of evidence, the question of the operativeness of the McDonough device, or the device upon which he predicates his right to a patent as the prior inventor over Bell, I submit that I am not satisfied that McDonough had produced a speaking-telephone prior to Bell's successful efforts in the same field, and I am not satisfied that a telephone constructed in accordance with the specification of McDonough and operated in conformity to this theory and conception would or could transmit articulate speech within the terms of the issue.

I have considered the affidavits of Professors Young and Brackett in connection with the evidence given by them in the case of the American Bell Telephone Company *v.* the Overland Telephone Company of New Jersey. Taking the evidence of those two scientists as a whole, I cannot find that they have demonstrated or that they unqualifiedly affirm the fact to be that a telephone using the make-and-break system, as contemplated by McDonough, will transmit articulate speech within the terms of the issue. It transpires in the cross-examination of these learned gentlemen that they assume that a battery telephone-transmitter may successfully transmit articulate speech when it is operated to make and break alternately the circuit in a manner indicated by Silvanus Thompson, as quoted by counsel in the course of the examination of Professor Young in the case last cited. The breaks spoken of by Silvanus Thompson, however, are not those contemplated by McDonough—that is, such as will occur when all points on one electrode are removed from all points on the other electrode; but, on the contrary, are such as occur when a limited number of points on one electrode are removed from the limited number of points on the other electrode. Such breaks cannot cause an interruption of the current, because contact between the electrodes, as a whole, is not interrupted, and what Silvanus Thompson and Professor Young described as *breaks* are, in effect, nothing but variations of contact, which, when occurring between the electrodes of a telephone, will give rise to an undulated current. It is true that Professor Young does intimate that it is even possible that the character of make-and-break which they (he and Professor Brackett) have in mind may, instead of a hindrance, be a real advantage in the electrical transmission of articulate speech. The better and controlling opinion is that a telephone constructed on the make-and-break system according to McDonough's conception will not talk. If that is so, clearly McDonough cannot succeed in the contest with Bell; but beyond that, it will be remembered that every incentive to diligence, every suggestion of honor and profit, was prompting McDonough, and, in fact, all the parties to this contest, to make haste in giving to the public an operative telephone; every condition and circumstance that could influence human action in such a matter reprehended delay and inaction. These contestants were in the field, fame and fortune were waiting at the goal of success for the inventor who first reached that point with a speaking-telephone. Each contestant knew it; each was trying to secure the reward that waited on success. The record discloses what was done by each and the measure of success attained.

Bell's patent was issued on the 1st of March, 1876. At the Centennial Exposition, held at Philadelphia that year (1876), he exhibited his telephone, and it was adjudged by such eminent scientists as Professor Henry, Sir William Thomson, of England, Professor Gray, one of the contestants herein, to be a success, and the world recognized Bell as the first inventor of a speaking-telephone. The indications are that it was not until the promised reward for so important a public service became visible that his claim to priority was called in question by any of the parties to this interference.

When considering the facts disclosed in this case I am forcibly reminded of the observation of Justice Grier in the case of *Goodyear* v. *Day* (2 Wallace, Jr., 298):

> When genius and patient perseverance have at length succeeded, in spite of sneers and scoffs, in perfecting some valuable invention or discovery, how seldom is it followed by reward. Envy robs him of the honor, while speculators, swindlers, and pirates rob him of the profits. Every unsuccessful experimenter who did or who did not come very near making the discovery now claims it. Every one who can invent an improvement or vary its form claims a right to pirate the original discovery. We need not summon Morse or Blanchard or Woodworth to prove that this is the usual history of every great discovery or invention.

And to the same effect in the case of *Howe* v. *Underwood* (1 Fisher, 162) Justice Sprague said:

> How invariable it is that after a great invention has been brought before the world, has become known to the public, and put in a form to be useful, that people start up in various places and declare that they invented the same thing long before. * * These pretended prior inventors had thought of such a thing, perhaps, but they had never carried it to the extent of making it of practical utility, so that the world could obtain possession of it; but when they find that another has completed that which they had begun they are astonished that they did not see, think they must have seen all that is necessary, and claim that they have invented it. After having seen what has been done the mind is very apt to blend subsequent information with prior recollections and confuse them together. Prophecy after the event is easy prophecy. I think that this is one of the cases in which several of the witnesses have been led into the illusion of believing that they knew before what they have learned or been taught by Mr. Howe's invention and specification.

I quote further the language of the case of *Smith* v. *Fay & Co.* (6 Fisher, 452):

> The presumption arising from silence, where there is so much interest to assert and occasion to assert it, and the party intelligent, and the results certain if the facts warranted it, has far more strength than any preponderance in number of witnesses and literal statements made by them in the case.

Digitized by Google

Also, *Hayden* v. *Suffolk Company* (4 Fisher, 101):

The greater the importance of the invention the less probable that if achieved it would have been laid aside and not extended itself to others interested in its use.

And, further, *Howe* v. *Underwood* (1 Fisher, 162):

It is a little remarkable that a perfect sewing machine * * * never produced work that anybody ever used for any purpose whatever; * * * that it was laid aside for years without producing either work or propagating itself in other machines ever after. *This is a phenomenon that requires to be accounted for.*

I have quoted these authorities which are cited in the brief of counsel for Bell, because the principle suggested and the ideas which are uppermost in the language quoted have had no little influence in bringing me to the conclusion I have reached in the determination of this case.

There is a disposition manifested by Bell's contestants to limit within the narrowest scope the invention claimed by Bell in his application of 1876, filed February 14th of that year. He then disclosed to the world what he had before invented—an art or method for transmitting articulate speech. His subsequent experiments demonstrated that the art or method discovered by him was what had been long sought, but not found, by his predecessors and rivals in the field of invention. He invented the art or method, and also an apparatus by which said art or method could be practiced. His claim as an inventor is for having done that thing in its entirety. The controlling issue in this contest is, however described and in howsoever many claims or subordinate issues it may find expression, a speaking-telephone. The invention of such a telephone involved necessarily the invention or discovery of the art or method not theretofore known of transmitting articulate speech. It would be impossible for an inventor to know that he had invented such an art until he had produced an apparatus which would enable him to practice it, for only by such a test could the fact be established. Hence it must appear that the inventor of the speaking-telephone must have invented the art and the apparatus, and I understand Bell's claim to cover the art and the apparatus by which he practiced said art. It occurs that Bell's competitors find in the various contrivances which they have invented certain elements which Bell now employs, and which they had employed in their unsuccessful efforts to transmit articulate speech. If not able to overthrow Bell's claim that he is the first inventor of a speaking-telephone, they seek to establish their claims to constituent elements, which they say Bell is not authorized to use without paying tribute to them. If they could succeed in this, it would be obvious, as counsel for Bell pertinently suggest, that these contestants will realize as great benefits from their several failures as Bell from his success. That all the efforts of the several contestants who had attempted to produce a speaking-telephone were failures seems clear from the record; that Bell was the first to give to the world the art of transmitting articulate speech, and the apparatus by which it could be successfully practiced, was substantially conceded for a long period after his success in that behalf was placed beyond doubt. Whether or not these several contestants had the instrumentalities and appliances at that time from which success might have been realized if those instrumentalities had been better understood is of little consequence. The history of their experiments is a history of recorded failures.

It is observed that Bell discovered, and his patent showed, that a certain combination of magnet, diaphragm, and armature, when arranged in a specified connection with other specified parts, constituted an apparatus which would transmit articulate speech. Up to this time no one else had done this, or had known it. The combination was the result of his conception and the outgrowth of his theory, and the apparatus, being a materialization of that conception and in conformity to that theory, was his original invention.

It is urged with great earnestness by counsel for McDonough that a telephone constructed after the manner shown in Bell's application would have been a failure, and would never have served as a valuable hint in constructing a commercial telephone, while he at the same time insists that McDonough has shown and described in his application a speaking-telephone. One very important truth may be mentioned in this connection, which goes a great way in resolving every doubt in favor of Bell as between him and McDonough. It is this: every improvement upon the Bell apparatus made in conformity to the specifications contained in Bell's original application tended to enhance the value of the telephone, and did, in fact, result in producing a thoroughly successful commercial instrument; while, on the other hand, every improvement of the McDonough device made in strict conformity to the requirements of his specification would tend to make the instrument worthless. The correctness of this proposition rests in large measure upon the theory that the underlying principle in the McDonough device was that it should operate by palpable make-and-break system, which involves a cessation of current at each vibration of the diaphragm. I am aware that this theory is assailed by the learned counsel for McDonough, and that he insists not only that the make-and-break is not incompatible with a successful speaking-telephone, but is in a measure a help. I accept the theory as fairly established that a telephone cannot be successfully operated which involves that system, and for the reason that there must be a time between the make-and-break when the diaphragm at the receiving end will not be under the control of the speaker, and will operate according to its own law.

The comments I have made touching the efforts of Voelker and McDonough apply with equal force, in the main, to those of the other parties in the contest with Bell. Edison is very properly accorded priority in issue D and No. 1.

A detailed review of each issue and each argument is not possible. I am satisfied from an examination of the evidence and consideration of the arguments submitted that the decision of the Board of Examiners-in-Chief should not be disturbed, and I do therefore approve and affirm it.

THE ELECTRIC LIGHT CONVENTION.

The convention of electric light representatives which met at Chicago on the 25th of February last, was peculiar, in that of all the people there assembled, to the number of 91 who registered on the secretary's book, not one could say definitely what the object of the gathering really was. So much of competition and jealousy has heretofore existed among the various interests, systems and manufacturers, to say nothing of inventors, that it was rather to be expected that some one had an ax to grind, in thus calling the various delegates together, and it was more than hinted at, that it was a little game in the interest of the "rowdy west," and probably Chicago, to do some awful thing to the Eastern gentlemen and their vested rights. Every right minded member of the convention however, came with a determination to sit down upon any "foul" which might become apparent, and the result was harmony and good feeling, from the first tap of the president's gavel, to the final close. It was evident from the "due form" of the presiding officer that he has somewhere wielded a gavel before he came to Chicago, and the justness of his ruling—albeit a little previous on one or two occasions—was satisfactory to all, and was evidenced in his unanimous election as president of the permanent organization. The amount of work done was far greater than could have been accomplished by a milder or less positive officer; and the success of the convention is largely attributable to his thoroughly business-like method.

The convention was called to order by W. A. Hovey, of the *Electrical Review*, who gave a short account of his fathering the idea of a convention, which had been prompted by that journal's correspondents. The morning session was short and was merely one of preliminary organization.

On convening at 2 P. M., the mayor of Chicago, Hon. Carter H. Harrison, was introduced and welcomed the delegates. He said that the impression prevailing abroad that Chicago did not want lights was an erroneous one. We wanted lights, but we wanted immunity from danger, both to life and property, and when these were guaranteed, Chicago would be to the fore in accepting and using them unstintedly. The convention had to deal with a monster, which it was for them to handle and render obedient, that it might not prove hurtful and mischievous. "The time was coming when bottled electricity would put a street car on wheels, and send it whirling to the suburbs, and also drive the elevated cars. In the name of Chicago I welcome you. Chicago is always ready to take in strangers."

Prof. Elisha Gray was introduced and made a short address. Among other suggestions he advocated the idea of the appointment of a sort of a "bureau of tribulation," with a secretary to whom all correspondence should be addressed, stating electrical and mechanical difficulties which might occur in the practical working of plants and machines, and that a record should be kept of the disease and the remedy, for the benefit of others. A delegate, who intended a still further elaboration of this idea failed to get his voice in, until after the permanent organization was effected, and as, under the constitution adopted he was excluded as ineligible, he failed to make his little speech.

The following officers were then chosen unanimously. President, J. F. Morrison, Baltimore; Vice-Presidents, H. M. Cleveland, Hartford, Conn., and J. H. Yarbrough, Nashville, Tenn.; Secretary, W. A. Hovey, New York. The Western Electric Co., through Mr. C. A. Brown, presented the president with a gavel representing a dynamo commutator, and trusted "that the convention in its deliberations will have as cohesive a number of segments," and the convention was declared in order for business.

The various suggestions which had been made by parties accepting invitations to the convention had been collated, and from these the committee appointed to formulate a list of themes for discussion, presented the following. 1. Incandescent lighting (particularly the distance from the dynamo at which they can profitably be run). 2. Locating and avoiding crosses with telephone wires. 3. Power and its conversion into light. 4. Electric light globes and shades. 5. Best modes of connecting dynamos with power. 6. Electric lighting by water-power. 7. Rates and rebates on electric lights by the year. 8. The use of electricity as applied to motors. 9. Where an electric light system requires No. 6 conductors, is it advisable to use Nos. 6 and

Digitized by Google

4 on the same line? 10. Will armatures become affected by frost in transportation? 11. Special insulation or guards at dangerous points and places. 12. Best methods of street lighting. 13. Experience and results in the use of underground conductors. 14. *Resolved*: That the fireman should receive more pay than the engineer. 15. Help generally. 16. Experience with naked and copper-plated carbons.

By the time the above list of topics had been read, the delegates began to get an inkling of what they had come for, and to some extent appreciated the amount of labor laid out for the convention.

The first topic was temporarily passed. The second, interference with telephone lines, was made highly interesting by the reading of a letter from a telephone superintendent, who complained bitterly of the aggression of the electric light people. The discussion—pretty much one-sided, inasmuch as it was an electric light convention—was likely to become interminable, and was adroitly disposed of by reference to a committee, which subsequently reported succinctly that the best thing the telephone people could do was to get out of the way, and suggested that all aerial electric light wires should be run as near as was safe, both going and returning, upon the same pole or cross arm. A member stated that he had never known a dynamo very seriously injured by contact with a telephone wire. A member during the discussion related some facts relative to the distance which the electrical tramp—induction—affected a telephone, but the president squelched him, evidently considering him an emissary from the enemy, and Prof. Gray's remarks on induction fared but little better. In the course of the discussion Chicago, as a city opposed to electric lights, came in for a share of the scoring.

President Morrison temporarily vacated the chair and took the floor to speak on the subject-matter suggested in the letter, which had evidently aroused the liveliest interest in the convention. He had hoped that some one else would have taken up the matter without gloves, but he felt that there was no use in trimming all around the important interests which lay at the bottom of this vexatious controversy. Personally he was friendly to the telephone people, but he had no patience with obstructions and impediments to the electric light work which came from them, for they were based upon sheer prejudice against those who were laboring in the same field, although in a different part of it. This induction business was a bugbear and had always been a bugbear. It was rather cool for the telephone companies to call the electric light their "new neighbor." The light was a neighbor of considerable age, though he would admit that the methods of application were new, since the distributing companies were only about four or five years old. He knew of cities which, unlike the city of Chicago, not only wanted the electric light, but would have it. The people of those cities regarded the common use of the electric light as a necessity, and it was no longer any luxury with them. It is the old business of the telegraph and the telephone over again. When the telephone came along the telegraph people raised a big outcry, and now when the electric light followed, the telephone people seemed anxious to obstruct it as much as they possibly could. He could tell them that in Baltimore they ran the telephone and electric light wires side by side on both sides of the street, and recently the light company had given the telephone people a right of way side by side with their own wires. There was no trouble about it, either. That there was some induction was true; there was humming, and the crackling sound, like the noise of burning sticks under a boiling pot, but it had been proved that this noise, though a little annoying, made no difference with the sound of the human voice. The tones of the voice could be heard clearly and distinctly, and the telephone service was not impaired at all. The telephone people had made the same protests and objections in Baltimore, had written very long letters, and threatened all sorts of things. The letters had been carefully filed away, and they had been told that the electric light system had come to stay and that had ended the matter. The people wanted the telephone and they wanted the electric light also, and they were going to have both.

Mr. Haskins volunteered, as a matter of information, to detail a practical case, illustrative of the distance at which a dynamo would make itself heard in a telephone receiver. He stated that a dynamo running within an inclosure on one side of a street in Chicago, the wires of which were upon the face of the building, the width of the sidewalk, and at least 20 feet below some telephone lines, was distinctly heard on other wires on the farther side of the telephone exchange, by secondary induction. Mr. Haskins was immediately sat down upon by the president—who is no light weight—under the impression that an enemy was in the camp. An attempted explanation effected nothing, and the speaker sat down—squelched.

The discussion was participated in by Messrs. Wadsworth of the Boulton Carbon Co., Hovey, Fletcher of Dixon, Ill., Weeks of Kansas City, and others.

Power and its conversion into light, was thoroughly discussed. Ide, of Ide engine fame, told how the Springfield, Ill. plant was run, and Frank Stewart, of Chicago, contended for direct belting from engine to dynamo. Weeks, of Kansas City, concurred. Sperry, of Chicago, advocated thin belting, and objected to perpendicular belting as the tendency was to make the dynamo jump. The president stated that in New York geared wheels were used, and belting discarded. He considered larger and fewer engines profitable, rather than a greater number of smaller ones. He evidently considered friction clutches a delusion and a snare. They had tried several experiments in Baltimore, and had come down to tight and loose pulleys, and were now working without difficulty. Mr. Morrison's remarks were interlarded with much that was facetious, but all to the point and his statements were listened to with profound interest.

Electric lighting by water-power, called up George Fletcher, of Dixon, Ill., whose description of his plant created much merriment, and some astonishment, as well. He said he paid $15 a month for an engineer, and was asked by a member where he got him; to which he replied that the Lord made him, but he didn't come from Chicago. He bought carbons at $15, a thousand, and when asked if his lights were satisfactory to his patrons, he thought they were, but perhaps some of them didn't know. A member (*sotto voce*) "He probably lights a blind asylum." The carbon folks were exercised about the price of carbons, and in reply to their interrogatories, he stated that his carbons came from Buffalo. Mr. Fletcher is running 30 lights, and his engineer is one of his planing mill hands, whose duties in the mill permit of his assuming the other task, at a slight advance in salary, and his power is a turbine wheel which also does double duty.

Rates and rebates on lights was discussed by Randolph of Rockford, who said in winter they ran 15½ hours in stores, and had three circuits which he shut down at 7, 8, and 9 o'clock and charged accordingly. Much talk was indulged in, and finally by way of bringing the matter of this and the preceding topic to a head, the chair appointed a committee to prepare and report comparative estimates of the cost of erecting and running a plant of 100 lights by water and steam-power. This was a case of fat and fire. With terror depicted in his countenance and "lightning in his eye," a delegate rose to protest against such an un-business like procedure. In a move of this nature he saw the immediate downfall of the whole industry. It would give away to the world all the secrets of the business. By a vote of the convention the committee was discharged on the spot.

Electricity as a motor was discussed by Mr. Hovey, who said that the question was now near the end of the experimental stage, and ready to be taken from the laboratory and placed on duty. Scientists, like Edison, were not practical men. Mechanics must now take hold of the question, to make the discoveries of the former class of workers available, and complete the work they had begun, and some one must lose money before this could be satisfactorily accomplished. Mr. Van Depoele, of Chicago, said the power of a motor could be controlled as well as could that of a steam engine. Mr. Sperry, of Chicago, advocated small motors to take the place of electric lights in seasons when these were not needed, to run fans for ventilating apartments, and so keep the plant alive the year through. Mr. Hochhausen, of New York, gave some information relative to European railways operated by motors, and said the Cleveland, O. street railway was the only one running in this country. Mr. Wadsworth of Cleveland had seen one in Boston. The doctrine of probabilities, or as it was termed "the law of average," here became the topic, apropos of the statement of a member that a large number of small motors, each of which would be compelled to remain idle during the shifting and preparing of its work, as in the case of machinists and turners, lathes, sewing machines, and the like. It was argued that this loss would be a gain to the party furnishing power, inasmuch as more power could be thus sold than was actually furnished. The president and several of the delegates were too conscientious to endorse the proposition. Banks which loan their deposits, telephone companies who cannot serve all their customers at once, gas and water companies, which could not possibly give a day's supply, if every customer was to draw on them at the same time, were cited as instances of similar scientific guess-work bases, but to no avail. The president and his honest followers were like Banquo's ghost—they would not down.

The next topic was the result of an inquiry from some one who had a circuit of No. 6 gauge wire, and wanted to extend it by the use of some No. 4 which he had, and the convention decided that he might. The convention then adjourned till 10 A. M., Feb. 27.

On re-convening, the president announced the topic "special insulation, or guards to insulation of lines at dangerous points and places," and called upon Mr. Haskins, of Chicago. Mr. H. detailed his ideas of insulation, and related his experience with underground terminals, explaining the spread of moisture, as I have mentioned in another portion of this letter. He also gave the results of experiments undertaken with a view of ascertaining the safest relative distance between positive and negative wires in the incandescent systems, in which he showed conclusively that the nearer together they are the better, where safety strips are used. These were given in full, in the February number of the ELECTRICIAN AND ELECTRICAL ENGINEER. Specific cases were referred to Mr. H., who prescribed for the symptoms given. Mr. Place, of Chicago, also talked high insulation.

"Will armatures become affected by frost in transportation?"

Mr. Van Depoele said he had examined one case, and the result

Digitized by Google

showed that the dynamo had been burned by being wrongly connected up, and the user had charged frost with the mischief. A case was mentioned where a dynamo was frosted in transit between St. Paul and Minneapolis, and the president (a Brush man) said it was probably a poor form of dynamo.

A delegate—"It was a Brush dynamo," and for once the presiding officer was staggered; but he did finally recover sufficiently during the thunder of applause, to remark in a faint whisper, "then there was something else the matter." The question was very decidedly negatived.

"Street lighting," and how best to do it was thoroughly discussed by advocates of the tower system and its opponents, the general impression prevailing that the former was adapted for smaller, and the pole system for larger communities.

Then the knotty question of how long a circuit can an incandescent system be made to operate satisfactorily, brought out much talk, but elicited little information. The question was apparently no easier of solution than that of the semi-idiotic child, who pulled at his mother's skirt, and asked, "Maw! Maw! How fast can a cow run up an alley a minute?" It was too much for the convention, which at once adjourned until 2 P. M.

Underground circuits could not well be handled satisfactorily, under the shadow of the Chicago "ground hog" ordinance, and that question was tabled.

The next topic was—"*Resolved*, that the fireman should receive more pay than the engineer." There was no one to advocate the affirmative, and the fireman's sun of glory did not rise.

The telephone trouble committee then reported, as I have abridged it above, encouraging the lesser lights to run metallic circuits, and use lightning arresters, etc. A remark by a member unheard generally, suggested the propriety of these troubled people keeping out of the way of the procession.

The carbon people had a benefit on the next topic. Much difference of opinion was expressed as to the relative value of the plain and copper-plated carbons. Mr. Wadsworth stated that the Boulton company was about to cease the coppering process. From the difference of opinion expressed it is evident that the matter is not yet sufficiently sifted to form proper conclusions. Mr. Arey, of the Buffalo works—he's the $15, a thousand fellow—gave as the measurement of a standard carbon $\frac{3}{10}$ of an ohm resistance, "for what it is worth."

The committee on permanent organization then reported, the result of which was the adoption of a constitution by "The National Electric Light Association," to which all companies, firms or individuals operating plants or manufacturing apparatus, are admitted on payment of an initiation fee of $10, and $10 annual dues. Outside parties connected with electric lighting, other than those owning or operating plants—the line of demarcation is not quite definite—may become associate members, with limited rights, at the same price; but like the steam dredge, which Paddy saw at work, "can't vote." An executive committee is the governing body, to be elected annually. The following officers provided for by the constitution, were then unanimously elected, to hold their positions for one year, or until the next election, President, J. F. Morrison, Baltimore, Md.; Vice-Presidents, H. W. Cleveland, Hartford, Conn.; E. R. Weeks, Kansas City, Mo.; J. H. Yarbrough, Nashville, Tenn.; Secretary and Treasurer, W. A. Hovey, New York (*Electrical Review*); Executive Committee, J. R. Fletcher, Dayton, O.; G. S. Bowen, Chicago, Ill.; W. Hochhausen, New York; Gilbert Donaldson, St. Paul, Minn.; Frank Ridlon, Boston, Mass.; James O'Connor, New Orleans, La.

In accepting the position of permanent president, Mr. Morrison gave the association many practical suggestions as to the possibilities of the organization, and the duty and responsibility of each member. All must do their part, and if each would bring to the next meeting of the association a record of the successes and trials of the year, the association would arrange all these various experiences in a tangible form for the benefit of all, and an immense good would result from this form of record and its dissemination. Enough had been done to show that this was practical, and taken as a whole, he considered the beginning which they had made a full guarantee of success.

Votes of thanks were tendered to the Grand Pacific proprietors and the press of the city, and at half-past three the convention adjourned to meet at Saratoga in July next, on notice from the secretary.

I look upon the convention as a grand success. The following is a list of those who recorded their names on the secretary's book.

J. F. Morrison; Sommerfield Baldwin, Brush Electric Co., Baltimore; Theo. P. Bailey, Chicago; A. N. Lane, Muskegon, Iowa; R. M. Johnson, Hyde Park, Ill.; J. H. Yarbrough, Nashville; R. T. Robinson, Providence; A. L. Ide, Springfield, Ill.; H. M. Cleveland, Schuyler Electric Light Co., Hartford; S. E. Locke, Schuyler Electric Light Co., Omaha; S. S. Badger, Badger Electric Light Co., Chicago; M. C. Bullock, Brush Electric Light Co., Chicago; C. J. Richards, Racine, Wis.; F. S. Terry, Electrical Supply Co., Chicago; J. H. Reid, Electrical Supply Co., Chicago; W. L. Bush, Van Depoele Co., Chicago; C. J. Van Depoele, Van Depoele Co., Chicago; E. J. O'Beirne, Star Iron Tower Co., Ft. Wayne, Ind.; W. A. Knapp, Railway Telegraph Supply Co., Chicago; W. T. Lewis, Thomson-Houston Co., Racine, Wis.; F. H. Angell, American Electrical Works, Providence; C. C. Curtis, Brush Co., Cleveland; E. D. Libbey, New England Glass Co., Boston; J. D. Robinson, New England Glass Co., Chicago; Geo. D. Fletcher, Van Depoele Co., Dixon, Ill.; Elmer A. Sperry, Sperry Electric Light Co., Chicago; Edwin Place, Sperry Electric Light Co., Chicago; Chas. E. French, Cleveland Carbon Co., Cleveland; R. J. Randolph, Rockford, Ill.; W. T. Powers, Grand Rapids Electric Light Co., Grand Rapids, Mich.; Geo. W. Carter, Van Depoele Co, Jackson, Mich.; E. T. Keim, United States Electric Light and Power Co., Dubuque, Iowa; C. B. Askew, St. Paul Electric Works, St Paul; Joseph Fleisheim, Electric Light Co., Menomonee, Mich.; Geo L. Crossman, Thomson-Houston Electric Light Co.: D. Jacobus, Van Depoele Co., Crookston, Minn.; E. M. Fox, E. Remington & Sons, Ilion, N. Y.; F. M. Mills, Thomson-Houston Co., Des Moines, Iowa; E. R. Montague, Brush Co., La Crosse, Wis.; H. C. Adams, Holmes, Booth & Haydens, N. Y.; A. W. McLaughlin, Boston; R. L. McDonald, Jenney Electric Co., Ft. Wayne, Ind.; Vernon Bell, Western Electric Co., Minneapolis, Minn.; Harold P. Brown, Chicago; Wm. H. Beach, Olmstead Electric Light Co, Minneapolis; T. P. Plumridge, American Carbon Co., Chicago; W. M. Goldthwaite, Electric Light Co., La Porte, Ind.; W. M. Goldthwaite, Electric Light Co., Adrian, Mich.; Albert L. Arey, Buffalo Electric Works, Buffalo; H. D. Stanley, Bridgeport Electric Light Co., Bridgeport, Conn.; Wm. A. Hovey, *Electrical Review*, New York; Charles W. Price, *Electrical Review*, Chicago; G. W. Parker, Parker-Russell Manufacturing Co., St. Louis; L. M. Fishback, Parker-Russell Manufacturing Co., St. Louis; W. Hochhausen, New York; John C. Fyfe, Nee Bau Electric Light Co., Chicago; W. A. Hammett, N. Y. Safety Steam Power Co., Chicago; Frank Stewart, Western Electric Co., Chicago; Chas. A. Brown, Western Electric Co., Chicago; George S. Bowen, Elgin Electric Light Co., Elgin, Ill.; W. H. Boulton and Geo. H. Wadsworth, Boulton Carbon Co., Cleveland, O.; E. R. Weeks, Thomson-Houston Electric Light Co., Kansas City, Mo.; Aaron K. Stiles, Van Depoele Co., Chicago; W. A. Kreidler, Correspondent, Chicago; Frank Ridlon, Brush Electric Light Co., Boston; R. T. McDonald, Jenney Electric Light Co., Ft. Wayne, Ind.; C. C. Warren, U. S. Electric Light Co., Chicago; W. J. Buckley, Excelsior Electric Light Co., Chicago; E. M. Barton, John Young, Western Electric Co., Chicago; C. C. Haskins, Chicago, C. A. Cotter, Ansonia Brass and Copper Co., Chicago; W. P. Hathaway, Fuller Electric Light Co., Milwaukee; W. F. Walworth and J. C. Neville, Manufacturing Electric Light Crossarms, South Bend, Ind.; E. B. Palmer, Sperry Electric Light Co., Chicago; H. L. Brintnell, Swift Electric Light Co., Saginaw, Mich.; J. H. Stanwood, Badger Electric Light Co., Chicago; L. W. Slack, Pittsburg Carbon Co., Pittsburg, Pa.; Elisha Gray, Chicago; H. W. Burgett, American Electrical and Illuminating Co., Boston; Gilbert Donaldson, Electric Light Co., St Paul; W. H. Keasel, Willoughby, Hill & Co., Chicago; D. R. Russell, Parker, Russell & Co., St. Louis; John R. Fletcher, Dayton Electric Light Co., Dayton, Ohio; C. H. Webster, Chicago; J. D. Simpson, Chicago.

CONVENTION NOTES.

A proposition was made by the president between meetings to "kill Haskins, and tear the word insulation out of the dictionary," and then he thought the electric light folks would have peace.

One member of the convention said that the reason he came was because he had received a circular from the company whose system he was using, advising him to stay away from the convention, and so he came for spite! Probably like the minister who visited a disreputable performance, so he could the better warn his flock from personal experience. That same company however, was represented by its chief inventor.

In conversation, between the acts, the telephone matter came up, and one member said that when he found himself in front of a procession, he generally took to the steps or the gutter; and he thought the old rule of the rail applicable to the telephone folks:

The rule of the rail; soon come or soon go,
Admitting of little delay;
If you go, get in quick—you are left if your'e slow,
Get out, and get out of the way.

A few of the members had a private session, on the night of the first day, which lasted well into the morning. Several were quite weary with their artistic efforts at coloring the town.

CHICAGO, March 4, 1885.

DEATH OF GENERAL STAGER.

Gen. Anson Stager died at his home in Chicago, at 3 o'clock A. M., March 26th. He was born in Ontario County, N. Y., April 20th 1825. His father was a manufacturer of edge tools at Rochester, N. Y. When 16 years of age he engaged in printing under the instruction of Henry O'Reilly, who afterward became a pioneer in the building and operating of telegraphs. O'Reilly

Digitized by Google

induced young Stager to follow him into this undeveloped enterprise, and when he had connected Philadelphia with Harrisburg the young man took charge of his first office at Lancaster, on this line, in the fall of 1846. He soon became an expert telegrapher, and in the extension of the lines west of the Alleghany mountains, he was transferred to Pittsburg. As the lines were carried westward through the Ohio and Mississippi valleys, this became an important station, and in its management the young man first gave evidence of the extraordinary administrative abilities which characterized his subsequent career. It may be mentioned that among the messenger boys in the Pittsburg office under Stager's administration were some who have since risen to high positions, among whom may be mentioned Andrew Carnegie, the great iron manufacturer, Robert Pitcairn, of the Pennsylvania railroad, and D. C. McCargo, of the Pennsylvania company. It was not long however before Cincinnati became the controlling point of the western telegraphic system, and he was placed in charge of that station, which soon acquired the well-deserved distinction of "the model telegraph station of America."

While at Cincinnati, he was employed at frequent intervals during the years 1848–'50, in making determinations of longitudes, "wave time" of electric currents, etc., for the U. S. Coast Survey under the direction of the late Prof. Sears C. Walker, in which important service he won new laurels.

While still acting at Cincinnati, the New York and Mississippi Valley company's lines, connecting Buffalo, N. Y. with Louisville, Ky., were projected, and Anson Stager was made the first general superintendent thereof in 1852. In July of the same year, through the absorption of the New York State Printing Telegraph Co.'s lines by the Mississippi Valley Printing Telegraph Co., Gen. Stager's supervision was extended over that state. Soon after this he was prominent in organizing the various lines and interests leased by and consolidated with the Western Union Telegraph Co., and upon the organization of that company he became its general superintendent. The extensive and elaborate system of railroad telegraphs in use on all the railroads in the west and northwest owes its origin to him. On one of Gen. Stager's many trips in the interests of his company an engine on the Pittsburg, Fort Wayne and Chicago Railroad broke down at night, nine miles from an office. Stager cut the wire and by touching the ends telegraphed to Pittsburg and Brighton for another engine. By fixing one end of the line above and the other beneath his tongue, the electric pulsations could be felt, and he thus received reply that another engine would be sent at once. This feat, then a novel one in telegraphy, gave him a wide celebrity, both in this country and abroad.

When Sumter was fired on the Governors of Ohio, Indiana and Illinois took possession of the wires in those states for military purposes and at once put Gen. Stager in charge of them as representing themselves. He accompanied Gen. McClellan in his West Virginia campaign, during which he established the first system of field telegraphs used during the rebellion. When Gen. McClellan was transferred to Washington he called Mr. Stager to that department to organize the military telegraph. This he accomplished, and remained in charge until November, 1861, when he was commissioned captain and assistant quartermaster, and, by order of the Secretary of War, was appointed Chief of the United States Military Telegraph throughout the country. Subsequently he was commissioned colonel and aide-de-camp, and was also placed in charge of the cipher correspondence of the Secretary of War. The cryptography used in this correspondence all through the war, which baffled the most persistent efforts of the rebel telegraphers and officers to translate, was in all its details his. Col. Stager remained in the service until September, 1865, and was breveted brigadier-general for valuable and meritorious services.

Following the close of the war, the consolidation of the Southwestern and American Telegraph companies with the Western Union made necessary a reorganization of the latter, and the general superintendency of the consolidated company was offered to, but declined by, Gen. Stager. A result was the creation of three grand divisions—the central, eastern and southern, Gen. Stager accepting the superintendency of the central, which left him in charge of his old territory, with headquarters at Cleveland. Four years later Cleveland became no longer a central point, and during the summer of 1869 the headquarters were transferred to Chicago. After coming to Chicago he became the leading western representative of the Vanderbilt interests. He founded the Western Electric Manufacturing Co., the largest manufactory of electrical machinery in the United States, and continued to be its president until Jan. 1st of the present year. Gen. Stager has been prominently identified with the development of the telephone business in Chicago and the northwest. He also took a prominent part in the introduction of the electric light, and has been the president of the Western Edison Electric Light Co. since its formation. Railroads also received a great deal of attention at his hands. Gen. Stager was married Nov. 14, 1847, to Miss Rebecca Sprague, of Buffalo. He lost his wife Nov. 22, 1883. Of his children only three are living—Mrs. F. S. Gorton, Mrs. Ralph W. Hicks, and Miss Ellen Sprague Stager.

FINANCIAL STATEMENT OF THE AMERICAN BELL TELEPHONE CO.

THE American Bell company issues the following statement of operations for ten months ended December 31, compared with 12 months ended Feb. 28, 1884. This is caused by a change in the financial year from Feb. 28 to Dec. 31 :

Earnings.	1883–4. (12 months.)	1884. (10 months.)
Rental of telephones	$1,695,678.58	$1,635,848.64
Sales of instruments and supplies	17,969.59	5,803.55
Royalty from manufacturers	4,837.74	....
Dividends	440,923.00	317,887.20
Commission from extra-territorial and branch lines	45,819.68	58,109.75
Commission from telegraph business	12,305.81	11,290.10
Interest	78,059.67	38,604 73
Totals	$2,295,594.07	$2,067,543.97
Expenses.		
Expenses of operation	$172,909.69	$198,553.59
Legal expenses	129,893.22	124,809.25
Interest and taxes	125,882.89	33,710.25
Depreciation	24,120.69	98.24
Commission	354,856.21	325,207.19
Royalty	12,500.00	10,000.00
Totals	$820,162.70	$687,378.52
Net earnings	$1,475,431.37	$1,380,165.45
Balance of income from previous year	168,081.54	348,884.17
Miscellaneous items to surplus account	91,291.87	34,918.45
Totals	$1,734,804.78	$1,763,968.07
Dividends declared	$1,051,479.00	$1,152,252.00
Extra dividend Dec. 15, 1884	....	288,063.00
Carried to surplus account	334,441.61.	323,653.07
Balance to income account	348,884.17	....
Totals	$1,734,804.78	$1,763,968.07

The assets and liabilities December 31, 1884, were :

Assets.		
Telephones	$558.319.51	....
Stocks	22,125,173.36	....
Merchandise and machinery	18,851.28	....
Lines	102,270.55	....
Bills and accounts receivable	681,493.74	....
Cash and deposits	520,536.33	....
Liabilities.		
Capital stock	....	$9,602,100.00
Loan of 1882 (convertible)	....	3,600.00
Bills and accounts payable*	....	516,935.81
Patent account (profit and loss)	....	9,540,120.31
Profit and loss	....	3.225,478.63
Reserve	....	61,297.59
Surplus	....	1,057,112.43
Total	$24,006,644.77	$24,006,644.77

*Of this amount $288,063 is the dividend payable January 15, 1885, to stockholders of record December 31, 1884.

NO PAY, NO WORK.

The new Receiver of the Bankers and Merchants' Telegraph Co., exhibited his profound knowledge of the labor question by issuing the following circular, on March 19th, which was bulletined in the main operating room, at 187 Broadway :—

To Employés: Appreciating fully the hardship to which the employés of this company have been subjected by reason of the failure to pay promptly the amount due, I have made a vigorous effort since becoming Receiver to secure advances in money sufficient to make a settlement of all outstanding labor debts from the 23d day of September, 1884, to the 1st day of March, 1885. My efforts have been so far successful that parties stand willing to advance me a sum sufficient to pay at once 70 per cent. of all claims of the class above mentioned within the above period, provided this sum shall be accepted in full settlement of the same. Notify me without delay whether it is acceptable to you. If the proposition is accepted, I contemplate paying hereafter all future claims for services promptly on the 10th day of each month.

When the night force went on duty they complied at once with Mr. Butler's request, to notify him without delay whether the terms were acceptable. A despatch was sent to that gentleman, at the Hoffman House, to the effect that unless the operators were assured by nine o'clock, that the money due them would be paid in full, they would leave their keys at that hour.

Digitized by Google

Receiver Butler appeared at the office personally at 8.45, P.M. He narrated the old plea of incoming administrations under such circumstances, that the treasury was empty; but that he had borrowed sufficient money to pay 70 per cent. of their claims, if they would sign receipts in full. Different propositions were made by each party, but the operators insisted upon the payments for February being made on the following day, and in full, according to their regular schedule. Mr. Butler not feeling confident that he could carry out the promise if made, refused to compromise himself, and accordingly, at nine o'clock 20 men put on their coats and left the office, leaving the manager and two chief operators on duty. Mr. Butler, it is said, was highly indignant at the stand taken by the men, and made the usual assertion, that the business could be done without them. If such was the case, there appears to have been no real foundation for his wrath. The force in the Boston office expressed their sympathy with the New York operators by following their example, although it is understood that they had no personal reasons for complaint. Quite a number of operators also suspended work in other cities. In consultation with a committee of the employés on the following morning, Mr. Butler agreed that the February arrearages should be paid on March 21st, and that thereafter payments would be made as regularly as possible. The men then assumed their duties, and, for the present, no more difficulty of this kind is apprehended.

PROGRESS OF INCANDESCENT LIGHTING IN THE UNITED STATES.

The following isolated plants have been recently introduced by the United States Electric Lighting Co., or are now in process of construction :—

Washington Building, N. Y., 900 lights; New York Post-Office, 1,200 lights; Frank Leslie's, N. Y., 200 lights; Union Ferry Co. (two new boats), 150 lights; Pennsylvania R. R. Station, Jersey City, 600 lights; Smith, Gray & Co., Brooklyn, 160 lights; Palmer House Barber Shop, Chicago, 300 lights; Royal Insurance Co., Chicago, 1,155 lights; Home Insurance Co., Chicago, 1,500 lights; U. S. Custom House and Post-Office at Chicago, 750 lights; do. Cincinnati, 800 lights; do. St. Louis, 750 lights; U. S. steel cruiser, Atlanta, 200 lights; Las Vegas Hot Springs Co., Hotel, New Mexico, 652 lights; Geo. H. Friend & Son, W. Carrollton, Ohio, 60 lights; College of Ottawa, Ottawa, Ont., 100 lights; New York & Phila. & N. R. R. Co., steamer Cape Charles, 75 lights; Middlings Purifier Co., Jackson, Miss., 250 lights; Nashville Cotton Co., Nashville, Tenn., 250 lights; P. Espinal, Theatre, Caracas, Venzuela, 500 lights; Battle House, Mobile, Ala., 200 lights; Fred. Hauson, Hotel au Claire, Wisconsin, 100 lights; Samuel Cupples's, Factory, St. Louis, Mo., 150 lamps; Huron Mills, Ypsilanti, Mich, 150 lights; U. S. Post-office, Philadelphia, Penn., 600 lights; E. W. Hydorn & Son, Troy, N. Y., 690 lights; A. S. Turner, Elmira, N. Y., 575 lights; Mortimer Building, New York, 100 lights; Hamilton Club, Brooklyn, 300 lights; Mutual Life Insurance Co., new building, New York, 750 lights. This last plant has been substituted for a large installation of Sawyer & Man lamps which has been in operation for lighting the building for some time past, but has been rejected as unsatisfactory, and the Weston incandescent system substituted for it.

DEATH OF SIR CURTIS LAMPSON.

A despatch from London, March 13, announced the death of Sir Curtis Miranda Lampson. He was born in Vermont, September 21, 1806, and in 1830 went to England, where he was naturalized in 1848. When the company was formed for laying the Atlantic cable in 1856 he was made one of the Board of Directors and became vice-chairman. His important services in this great enterprise were acknowledged in a letter from Lord Derby to Sir Stafford Northcote, who presided at the banquet given in Liverpool, October 1, 1866, in honor of those gentlemen who had taken an active part in the laying of the cable. He was made a baronet November 13, 1866. He was Deputy Governor of the Hudson Bay Company and was one of the Trustees of the Peabody fund.

AN ELECTRIC RAILWAY IN MARYLAND.

The *Maryland Journal* says :—The Union Passenger Railway Co., of Baltimore, has commenced the building of a branch connection to Mt. Vernon, Hampden and Woodbury, in which electricity will figure as the motive power. The electric conductor will be a third rail laid in the centre of the regular rails. The cars will be drawn by motors with electric machinery. The contact between the electric rail and the motor is by a wheel, which runs over the rail, picking up the electricity. A motor, independent of the cars, is being made to try the experiment, and if it is successful, it is likely that the future motors will be part of the cars, so that one man may run the motor and act as collector of fares too. It is claimed for the new system that it will be cheaper than horses; that there will be no noise, no smoke and no cinders, and that it will make from eight to ten miles an hour. The pressing of a finger against a button is all that is required to manage the motors. General superintendent Robbins says that if the experiment turns out all right on this branch road, with its steep grades, the system will work satisfactory anywhere. The length of the new road is two miles and a quarter, and it is expected to be ready for use about the middle of April.

INCANDESCENT LAMPS IN ENGLAND.

We are informed on good authority that the output of incandescent lamps in England, at the present time, is in the neighborhood of 20,000 per week. Of this number about 13,000 are manufactured by the Swan company, who find it difficult even at this rate to keep up with their orders. Woodhouse and Rawson are making about 4,000, and the Victoria company about 2,000, the balance being the product of several of the smaller establishments. This appears to be largely in excess of the production in the United States.

THE TELEPHONE WAR IN CANADA.

A despatch from Montreal, March 19th, says the Dominion Telephone Co. having been successful in proceedings before the Minister of Agriculture against the Bell Telephone Co., and having obtained the annulment of the Bell patent, have to-day instituted similar proceedings for the annulling of the Blake, Phelps. Anders, and Edison patents. The Bell company, after a long fight in the United States, acquired these patents. A petition has been drawn up on behalf of the Dominion company and will be presented to the Minister of Agriculture in a few days. It is held by the Dominion company that the Bell company do not manufacture their instruments here, that they have all along imported them into the country, and have refused to sell the patent to any one, thereby forfeiting their rights and privileges under the act.

THE NEW YORK ELECTRICAL SOCIETY.

At the regular meeting held March 11th the following officers were elected for the ensuing year :

President—P. H. Van Der Weyde. *Vice-Presidents*—George B. Scott, George A. Hamilton, T. A. Edison, W. J. Johnston, C. O. Mailloux and George Worthington. *Treasurer*—F. W. Jones. *Recording Secretary*, A. A. Knudson. *Executive Committee*—P. H. Van Der Weyde, George B. Scott, F. W. Jones, E. L. Bradley, J. A. Seely, H. A. Sinclair, Eugene Lynch, Jr., John M. Pendleton, A. A. Knudson.

WESTERN UNION EARNINGS.

The following is the financial report issued by the Western Union Telegraph Co. for the quarter ending March 31, 1885 :

The net revenues for the quarter ending December 31 were reported at $1,415,846.71, which, added to $4,159,190.57, the previously reported surplus, gave the company $5,575,037.28. Appropriations for dividend, interest on bonds and sinking funds reduced this amount to $4,231,667.06, which was the surplus reported to be on hand January 1, 1885. The statement for the present quarter is as follows :

Net revenues based upon nearly completed returns for January, partial returns for February, and estimating the business for March		$1,350,000 00
Add surplus January 1		4,231,667 06
Total		$5,581,667 06
Interest on bonded debt	$123,500	
Sinking funds	20,000—	143,500 00
Balance		5,438,167 06
Dividend of 1⅛ per cent. on the capital stock		1,199,835 00
Deducting which leaves a surplus, after paying dividend, of		$4,238,332 06

TELEPHONY ON UNDERGROUND WIRES.

Dr. Jacques, electrician of the Bell Telephone Co., has carefully investigated the problem of telephonic transmission upon underground wires, and finds the results to be satisfactory so long as the product of the electrostatic capacity of the circuit in microfarads when multiplied into its resistance in ohms does not exceed 18.000. When this product exceeds 30.000, the articulation is entirely unintelligible. With an insulated conductor like that of the average submarine cable, having, per knot, a resistance of 11.5 ohms and a capacity of 280 mf., the limit of good speaking would be about 6 miles, and of intelligible speaking about 10 miles.

ELECTRIC LIGHT AND POWER.

Domestic.

Electric light companies have been formed in Columbia and Lancaster, Penn.

A new stock company is soon to be formed at Chicago for the purpose of manufacturing a new system for operating incandescent electric lights, invented by Harold P. Brown, electrical engineer. The incorporators of the proposed company comprise prominent capitalists of Chicago and Boston.

The East Cleveland street railway company of Cleveland, O. is completing arrangements for running the cars of the Euclid avenue, Cedar avenue and Garden street lines with electricity, on the Knight-Bentley system. For the present the new system will be applied to that portion of the lines running east of their re-

Digitized by Google

spective stables. A new building will probably be erected at the Cedar avenue stables for engines, boilers and dynamos. The trial of their experimental car on the Garden street line during the winter months seems to have been fairly satisfactory. It is expected to have the new plant in operation inside of three months.

Foreign.

The Manchester *Mechanical World* says: We are glad to notice the steady increase there is in the number of corn mills being lighted with the incandescent lamp. Messrs. Sugden and Sons, of Brighouse, have recently lighted one of their Brighouse mills; their mill at Shorefoot, Huddersfield, has been lighted for some time. The dynamos are driven from the main machinery, and no irregularity or "pulsation" in the light has been observed. The number of lights required for a good-sized corn mill is about 60, and the light given is found greatly superior to the old plan of oil lamps and candles. But the greatest and most important advantage in the incandescent lamp is in its perfect immunity from causing any explosion. A large number of corn mills have been fitted up in Ireland, and if it were not for the great depression in the corn, etc., trade, there would not be any important mill without the "electric light."

The first electric railway opened in the United Kingdom was that between Portrush and the Causeway. Ireland will soon possess a second line. The Bessbrook Spinning Co., are constructing at their own expense a tram-way from Bessbrook to Newry. It will be opened in a few weeks.

The Hammond Electric Light and Power Supply Co., is to light some of the leading thoroughfares of London, and is to have the privilege of opening roads for private lighting without special Act of Parliament. This is the first substantial triumph of the electric light in the metropolis.

The Colchester (England) electric light installation of the South-eastern Brush company, the only central station system in England, will doubtless suspend operations owing to lack of financial support.

MISCELLANEOUS.

The Society of Telegraph Engineers and Electricians, founded in London, in 1871, under the name of the Society of Telegraph Engineers has to-day 1,256 members, of whom 369 are active, 179 are foreign, 668 are associates, 37 students, and 3 honorary.

During the year 1884 the Underwriters' Fire Patrol of San Francisco responded to 239 bell alarms, 33 still and 47 telephone alarms of which 15 were false.

MANUFACTURING AND TRADE NOTES.

Pope, Cole and Co., proprietors of the Baltimore Copper Works, have suspended. They have for several years past been extensive manufacturers of blue vitriol, supplying the Western Union Telegraph Co., and other large consumers.

The Buckeye Engine Co., Salem, O., is completing an order for five 50 h. p. self-contained steam engines for the Municipal Electric Light Co., Brooklyn, N. Y., and one for Oswego, N. Y.

The Excelsior Electric Apparatus Co., No. 61 Nassau street, is selling the new electric lamp scarf pin with battery, for which a patent was recently granted to Mr. A. Haid.

THE TELEGRAPH.

The office of the Bankers and Merchants' Telegraph Co. in Paterson is closed, and a paper pasted on the door declares that the landlord seized on all the effects of the company in Paterson for two months' back rent for the office.

The Baltimore and Ohio Telegraph Co., opened for business at York, Pa., on March 3d, the line from Baltimore (60 miles) having been constructed within 14 days, during which time the thermometer was usually below zero.

The directors of the Baltimore and Ohio Railroad Co. have adopted a resolution ratifying and confirming all previous action of the executive officers in regard to the expenditures required for the extension of the Baltimore and Ohio telegraph system.

The new line of the Baltimore and Ohio company has been completed to New Orleans.

Daniel S. Robeson, a stockholder in the American Rapid Telegraph Co., in behalf of himself and other stockholders similarly situated, has filed a bill in equity in the United States Circuit Court at Boston, against the company, Anthony W. Dimock, and others, charging that the defendants have made undue preferences and created liens on the property and assets of the company in favor of the Bankers and Merchants' Telegraph Co., and asks for an accounting between the two companies and the appointment of a Receiver of the American Rapid Telegraph Co. A restraining order has been issued by the court.

The Eastern Union Telegraph Co., at their annual meeting, held at Greenpoint, elected the following officers for the ensuing year: president, John B. Young; superintendent, W. F. Hammond; secretary and treasurer, William H. Wiggins. A dividend of 22 per cent. was declared.

THE TELEPHONE.

At the annual meeting of the Bell Telephone Co., of Philadelphia, the present directors were re-elected. Henry Bentley was also re-elected president, with Dr. S. M. Plush, general manager, A. A. Ziegler, treasurer, and George W. Snyder, superintendent.

The directors of the Erie Telegraph and Telephone Co., have accepted the resignation of W. A. Ingham as president, and filled the vacancy by the election of James W. Bennett.

Judge Wallace has issued a preliminary injunction restraining the Baxter Telephone and Telegraph Co., of central New York, from conducting a telephone business. This is a sub-company of the Baxter-Overland doing business at Utica. There was a company using the Bell patents there, and the Baxter-Overland came in as a competitor.

There were sold at auction March 11th, 900 shares Molecular Telephone Co. ($100) at 6, 250 shares Molecular District Telegraph and Telephone Co. ($25) at 5, 700 shares Harlem District Telegraph Co. ($10) $400 for the lot.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER *by* Pope & Edgecomb, *Solicitors of Patents for Electrical Inventions*, 59 *Wall Street*, *New York city*.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From February 24, to March 17, 1885 (inclusive).

Alarms and Signals:—*Fire Alarm Signal Box*, J. Young, 313,040, Feb. 24. *Thermostat*, F. H. Prentiss and J. A. Tilden, 313,523, March 10. *Messenger Signal and Fire Alarm Apparatus*, J. J. O'Neill, 313,610. *Automatic Signal Controlling Apparatus*, E. R. Gill, 313,720. *Signaling Apparatus*, J. P. Tirrell, 313,784. *Apparatus for Operating Bells*, H. E. Waite and S. H. Bartlett, 313,788, 313,789. *Automatic Circuit Changer and Alarm*, W. B. Van Size and T. D. Lockwood, 313,841. *Bell*, C. E. Kells, Jr., 313,941, March 17.

Commutators:—*Automatic Cut-out*, J. Du Shane, 312,985, Feb. 24; J. B. May, 313,091, March 3; E. Gannaway, 313,318. *Contact Breaker*, G. S. Maxwell, 313,605, March 10.

Conductors, Insulators, Supports and Systems:—*Conductors*, W. R. Patterson, 10,563, re-issue, Feb. 24; C. M. Thompson and C. R. Eberle, 312,673; S. F. Shelbourne, 313,380, March 3. *System of Lighting by Secondary Batteries*, A. H. Bauer, 312,698, Feb. 24. *Cable Hanger*, W. R. Patterson, 312,755. *Electrical Conducting Material*, C. S. Bradley, 312,803. *Fire Engine System*, S. S. Wheeler, 312,939. *Circuit*, H. F. Campbell, 313,053, March 3. *Cable*, W. H. Eckert, J. A. Seely and E. A. Eckert, 313,305. *Hanger for Cables*, same, 313,410. *Clamp for Binding Wire to Insulators*, W. H. Sawyer, 313.377. *Clamp for Electrical Purposes*, W. S. Platt, 313,616, March 10. *Apparatus for Utilizing the Current Force of Flowing Waters in Producing Electric Currents*, A. Man, 313,746.

Dynamo Machines and Motors:—*Regulator for Motors*, F. J. Sprague, 313,247, March 3. *Regulator for Dynamos*, F. G. Waterhouse, 313,561, March 10. *Dynamo*, W. P. Freeman, 313,488; W. M. Mordey, 312,745, Feb. 24: A. Reckenzaun, 313,884, March 17. *Armature for*, C. E. Brush, 312,807, Feb. 24; W. Stanley, Jr., 313,894, March 17. *Commutator for*, W. P. Freeman, 313,489, March 10. *Motor*, F. J. Sprague, 313,546.

Galvanic Batteries:—*Amalgamating Zincs for*, W. S. Platt, 313,615, March 10. *Galvanic Therapeutic Apparatus*, T. Schmauserx, 312,660, Feb. 24.

Ignition:—*Shell Fuse*, E. L. Zalinski, 313,150, March 3. *Gas Lighter*, C. W. Weiss, 314,088, March 17; J. Geary, 314,119.

Lamps and Appurtenances:—*Support*, F. U. Adams, 312,789, Feb. 24. *Lamp Controlling Mechanism*, E. H. Amet, 312,944. *Vacuum Pump*, R. F. Barnes, 312,951. *Arc-Lamps*, M. N. Lynn, 313,006; C. O. Mailloux, 313,436, 313,437, March 3; W. P. Freeman, 313,487, March 10. *Lamp for Locomotives*, M. N. Lynn, 313,009, Feb. 24. *Focusing Arc-Lamp*, L. G. Woolley, 313,039. *Electric Jewelry*, A. Haid, 313,726, March 10. *Mouth and Throat Illuminator*, E. T. Starr, 313,782, 313,783. *Method of Protecting Incandescent Lamps*, N. S. White, 314,208, March 17. *Holder for Incandescent Lamps*, A. Swan, 313,965.

Metallurgy:—*Apparatus for Treating Metals by Electrolysis*, H. R. Cassell, 312,814, Feb. 24. *Apparatus for Electroplating*, D. Appleton, 313,569, March 10.

Miscellaneous:—*Surveying Instrument*, J. Hale, 313,494, March 10. *Fare Register*, C. A. Neuert, 313,513. *Apparatus for Controlling the Flow of Gases at a Distance*, F. L. Muratori and E. Cros, 314,188, March 17. *Indicator for Pool Tables*, 313,404, March 3. *Globe*, F. P. Montgomery, 313,752, March 10. *Electrotype Shell and Base*. G. W. and J. R. Cummings, 313,812. *Electro-Magnet*, E. D. McCracken, 314,041, March 17. *Safety Device for Elevators*, R. M. Curtiss, 314,167. *Automatic Steering Apparatus*, C. H. Washburn, 313,901.

Railways and Appliances:—*Signaling Apparatus*, W. Hadden, 312,627, Feb. 24. *Torpedo for Railway Signals*, S. F. Allen, 313,151, March 3. *Railway Alarm Mechanism*, W. M. Pease, 313,614, March 10.

Storage Batteries:—C. S. Bradley, 312,802, Feb. 24. *Electrolytic Fluid for*, W. E. Case, 313,058, March 3. *Apparatus for Charging and Discharging*, W. Stanley, 313,117.

Telegraphs:—*Combined Telegraph Relay and Telephone*, H. C. Strong, 312,670, Feb. 24. *Repeater for Submarine Cables*, M. Farmer, 312,831. *Municipal Telegraph*, J. C. Wilson, 313,147, March 3. *Printing Telegraph*, G. A. Cassagnes, 313,175, 313,176; H. Van Hoevenbergh, 313,786, March 10. *Multiplex*, C. G. Burke, 313,298, March 3. *Telegraphic Apparatus*, C. W. Williams, E. B. Ives and G. S. Barnum, 313,462. *Automatic Chemical Telegraph*, C. Westbrook, 313,791, March 10. *Automatic Telegraphy*, same, 313,792. *Means for Preventing False Signals Upon Reversals in Quadruplex*, H. Van Hoevenbergh, 313,787. *Chemical Quotation Telegraph*, T. A. Edison and P. Kenny, 314,115, March 17.

Telephone Systems and Apparatus:—*Telephone*, W. Hadden, 312,841, 312,842, Feb. 24. *Switch*, same, 312,843. *Battery Telephone*, T. D. Lockwood, 312,871. *Telephonic Apparatus*, C. A. Randall, 312,896. *Combined Telephone Receiver and Circuit Breaker*, W. H. Eckert, J. A. Seely and E. A. Eckert, 313,409, March 3. *Automatic Shunt for Telephone Lines*, 313,640, March 10. *Telephonic Connection*, 313,731. *Support for Transmitters*, H. B. Lytle and J. A. McCoy, 313,828. *Office Connection for Telephone Exchanges*, same, 313,829. *Telephone Receivers*, T. F. Taylor, 314,155, 314,156, 314,157.

Thermo-Electric Battery:—D. Lautensack, 313,215, March 3.

NEW YORK, MAY, 1885.

ELECTRICAL PATENTS AND ELECTRICAL LITIGATION.

THE month of April, 1885, seems likely to become a somewhat memorable one in the annals of electrical patent litigation. It will be recollected that a few weeks since Judge Shipman, of the United States Circuit Court, denied the injunction which had been asked for by the Gold & Stock Telegraph Company to restrain the operations of its rival, the Commercial Telegram Company, on the ground of infringement upon the patent of E. A. Calahan, substantially for the reason that the patent was vague in its phraseology, so that its exact meaning could not be summarily determined.

The satisfaction with which this decision was received by the Commercial Telegram Company was, however, destined to be of short duration. The complainants succeeded in having the case brought almost immediately to final hearing, and as the defendants had neglected to take testimony within the time allotted, they were compelled to go to hearing without it, and to depend mainly upon the cross-examination of the complainants' witnesses to make out their defense. On April 1 Judge Shipman filed an opinion in favor of the complainant company, adjudging the Field printer employed by the defendants to be an infringement of the second claim of the Calahan patent, for two independent type-wheels printing in two lines upon one strip of paper. An injunction was subsequently issued against the Commercial company, to take effect on Saturday, April 11. Accordingly, on that day the Commercial company tied up one type-wheel on each of their instruments, some 300 in number, but continued to furnish quotations by printing with the alphabetical type-wheel only. They succeeded in getting through with the work more rapidly than might have been expected, although the peculiar abbreviations used, such as "ath" for eighth, "aty" for eighty, however familiar they may have been to the old school of printing telegraph operators, must have been like so much Greek to many of the brokers. In fact, if it had been Hebrew it would probably have been far more intelligible, at least to some of them.

The situation was further complicated by the fact that the Calahan patent expired by limitation on April 21. The day before the injunction went into effect, Mr. Buckingham, the counsel of the Gold & Stock company, addressed a circular to the subscribers of the Commercial company, notifying them that printing even with one type-wheel constituted an infringement, that suits would be instituted against the individual users, and that the injunction would not permit the use, after the expiration of the patent, of infringing instruments which had been made during its lifetime. The Commercial company the next day issued a counter proclamation, containing an opinion signed by their counsel, Roscoe Conkling and Samuel A. Duncan, to the effect that printing with one wheel did not constitute an infringement. It also commenced an action in the Superior Court against the Gold & Stock company, claiming $50,000 damages for an alleged libel contained in Mr. Buckingham's circular.

Thus matters rested until the day after the expiration of the Calahan patent, when the Commercial company proceeded to operate both wheels of their instruments in the usual manner, regardless of a second proclamation which had in the meantime been sent out by Mr. Buckingham, that the injunction would be still of full force and effect after the expiration of the patent, in respect to the use of instruments constructed in violation of the patent. So far as we can judge from the tenor of previous decisions involving the same point, the Gold & Stock company appear to have the law on their side. Precisely what will be the outcome of this apparent defiance of the injunction of the United States Court cannot yet be predicted. The action has undoubtedly been taken under the advice of eminent counsel, and the result will be awaited with interest.

A decision was rendered by the Supreme Court of the United States on April 6, in the case of the Electric Railway Signal Company against the Hall Railway Signal Company, which, although not one of especial importance, is interesting as having been the first electrical case before the Supreme Court since the celebrated telegraph suit of O'Reilly v. Morse, in 1852. It was commenced in Connecticut in 1875, and decided by Judge Shipman in the Circuit Court in favor of the defendants, on the ground that their assignee was in law the first inventor, a decision which, in view of the proved facts in the case, was regarded with great surprise in legal circles. Upon appeal the Supreme Court also decided for the defendants, but this time on the ground that their apparatus did not infringe the complainant's patent. The invention involved in the suit, although in very extensive practical use at one time, is now obsolete, having been superseded by improved systems.

The Supreme Court also decided on April 20 a case of considerable interest, involving the polishing and hard finishing of insulated electric wires, an invention which has practically become a very important one, on account of the enormous growth of the electric wire industry within the

Digitized by Google

past few years. The original suit was brought in Connecticut by the Western Electric Manufacturing Company of Chicago, against the Ansonia Brass and Copper Company, for infringement of two patents, one for the process of waxing, compressing and polishing the braided coating of the wire, and the other for the manufactured article thus produced. Judge Shipman, of the Circuit Court, held that inasmuch as the same process had before been applied to wires coated with cloth and saturated with bitumen or fatty substance, that no invention was required to apply this old process to a new use. The Supreme Court now affirms this decision, and thus this important process is thrown open to the public. It is certainly to be regretted that the inventor of so important an improvement, from a practical point of view, should not have been adequately rewarded. Any one accustomed to handling the rough, greasy and unhandsome wires which were in universal use before the introduction of this improvement, cannot feel otherwise than grateful to the person to whom they are indebted for the introduction of the elegant and highly finished products of to-day.

A reference to the list published in another column will show that besides the Calahan printing telegraph patent, a number of other patents of considerable celebrity have expired within a few days, among others the celebrated Page patent, the great electric bug-a-boo of the past 15 years, which has been so often employed by the Western Union Telegraph Company to threaten and annoy its rivals. No serious attempt was ever made to enforce it, so far as relates to telegraphic apparatus, although a suit brought against the Holmes Burglar Alarm Telegraph Company resulted in the claims of the patent being sustained, so far as its application to that apparatus was concerned. Many important patents affecting electrical interests will expire within the next few years, whereby the field open to inventors will be perceptibly broadened, and they will be better enabled to work out their ideas without laying themselves under tribute to their half-forgotten predecessors.

THE PERIODICAL REVOLUTION IN TELEGRAPHY.

While state legislatures and the public press, are actively engaged in ostensible efforts to protect the people from the encroachments of monopolies, comparatively little attention is paid to the suppression of various schemes for swindling would-be investors, based upon alleged marvelous inventions. As we have often heretofore had occasion to point out, electricity affords a peculiarly promising field for the exploitation of questionable enterprises of this character, and as the general public apparently do not consider it worth their while to keep informed upon the actual progress of invention, unscrupulous adventurers take advantage of this state of affairs, to form companies, sell stock, and secure the spoils before the visionary character of their projects is exposed.

A recent example under the old, old title of a "Revolution in Telegraphy" has recently been brought out in a neighboring city. It is stated that the instrument to be used is provided with a key-board like a type-writer, and as the letters are plainly marked on their respective keys, it is obvious that no skill is required in the transmission of messages. Indeed it is reported that at an exhibition trial a non-expert easily printed at the rate of forty or fifty words a minute That this statement is false, is obvious to any person familiar with key-board manipulation. Those who imagine that the selection of letters is the only qualification required for a transmitting operator, evince their entire ignorance of the business. By the same process of reasoning, it might with equal truth be asserted that a compositor would require no training, if the boxes in a type-case were lettered, or that any ordinary person might become an expert pianist, immediately upon becoming familiar with the reading of music, provided the keys of the instrument were properly identified.

Another remarkable feature of this wonderful instrument upon which much stress is laid, is that it prints a duplicate copy at the sending station so that the operator may at once detect any error which he may have made. As this can be done by the printing instruments now in use without the least alteration, but is dispensed with in commercial telegraphy because it is of no practical utility, this alleged improvement is not worthy of mention. The same argument applies to the secrecy of the system, as it is practically impossible to read by sound from any printer, although there may perhaps be found an occasional expert who can read from the vibrations of a step-by-step instrument using a single type-wheel. The idea that any system of this character will, as is asserted, supersede both the Morse telegraph and the telephone, is evidently based upon pure ignorance or worse, as the improvements to which special attention is called, are either such as already exist, possibly in other forms, or they are wholly unnecessary in actual practice. It is claimed that the effect of the introduction of this new system, will be the opening of some 40,000 new telegraph stations in railroad and express offices throughout the United States where none now exist. There is no particular reason why these stations may not now be opened if necessary, using the ordinary Morse register, which any person of average intelligence can learn to operate in one-quarter the time that they can a key-board printer. So long as a new crop of adventurers matures every few years, such schemes will continue to be published broadcast, with the hope of securing a fresh grist of victims; but it is to be regretted that their misleading prospectuses are allowed to appear in the guise of legitimate news in the columns of respectable journals whose business is supposed to be to protect the public from such questionable projects, rather than to assist in their consummation.

TELEPHONES FOR THE MILLION.

OUR rural friends are suffering from a lack of telephones, or at least they think they are, in every household. They would like to have them furnished gratuitously, but as no practical plan has yet been proposed by which this desideratum can be attained, they petition the state legislature for a reduction in rates. The comparatively unimportant fact that they are paying about two dollars more per ton for coal than they ought, is apparently not worthy of serious attention. If coal gets too high, they manage to get along without it, but telephones are a necessity of human existence which they must be permitted to enjoy at a reasonable price. Considerable curiosity has been aroused as to what might be esteemed the proper

Digitized by Google

figure for telephone rental by these helpless victims of a grinding monopoly. Recent action on the part of the collective wisdom of the Indiana legislature has placed the limit at three dollars per month, or about ten cents each day. We have yet to learn whether the telephone companies have expressed their willingness to comply with the rate thus arbitrarily established, or if any provision has been made by the legislature compelling the companies to continue the business of leasing telephones to the Hoosiers at unremunerative rates. The rate for telephones in New York city is $150 per year, yet we have heard nothing as yet of any petitions to the legislature to reduce the rentals. On the other hand, the state is actually forcing existing companies to expend large amounts for subterranean construction, which will render the maintenance and possibly the increase of existing rates an inevitable necessity. No fair-minded person can reasonably object to the earning of moderate profits by local telephone companies, otherwise there would be no incentive to the establishment of exchanges. That they have already found a field in towns which would barely maintain a country newspaper, proves that the general rate is not too high, otherwise a sufficient number of subscribers would not have been obtained, to support them.

A much more sensible proceeding would be for the legislature to compel livery-stable keepers to rent their horses and carriages at ten cents a day. Everybody has almost daily use for a horse and carriage, but they cannot begin to afford to pay the extortionate prices charged by the livery-men, and so they are compelled to trudge wearily on foot, while it is well known that no person who values his peace and comfort would have a telephone in his house at any price,—unless he is a member of the Indiana legislature.

A FLOURISHING INSTITUTION.

The American Institute of Electrical Engineers will hold their annual meeting for the reading of papers and election of officers for the ensuing year in this city on the 19th of the present month. It is to be hoped that there will be a full attendance of members of the Institute and others, as a number of papers of unusual interest and value have been promised for this meeting. The Institute has recently issued its first volume of transactions, a more particular reference to which will be found in another column. The exceptionally high character of some, and in fact most, of the papers read at Philadelphia, gives us reason to look forward to an occasion of unusual interest. The success of the Institute during the first year of its existence has been unusually gratifying, especially to those who, not without the expenditure of considerable time and labor, effected the preliminary organization and started the society in its career. The present membership comprises many of the ablest electricians and electrical engineers in the United States, and it represents almost every department of industry in which electricity finds a place. Dr. Norvin Green, president of the Western Union Telegraph Company, has held the office of president during the year, and the Institute has reason to feel greatly indebted to him for the careful personal attention he has given to its concerns, and the active interest in its welfare which he has exhibited during his term of office. It goes without saying that the unanimous voice of the members will be in favor of his re-election.

We learn that the society is in excellent financial condition, and it appears to have established itself on a permanent basis. By the courtesy of the American Institute of Civil Engineers, the council meetings during the past year have been held at their rooms. It is understood, however, that a movement is on foot among the different scientific and other similar societies in New York city to secure a permanent fire-proof building for the reception of their valuable libraries, collections and other properties. These are collectively of enormous value, and their loss by fire would be absolutely irreparable. It is proposed that each society have its own special rooms, while a general auditorium for annual meetings and the like will be provided, the use of which will be common to all. We believe that the time is ripe for this undertaking, and we see no serious difficulty in the way of its being carried out successfully at an early day. It is probable that capitalists may easily be found who will undertake to erect a suitable building in a central location, provided all the societies, or a sufficient number of them, would unite and take permanent leases of their apartments.

The Institute of Electrical Engineers is, as we are pleased to learn, lending its active co-operation to this project, in which effort we wish it every success.

DARKNESS PREFERRED TO LIGHT.

At a meeting of the New York Board of Aldermen April 24th, an estimate of the comparative cost of street lighting by gas and electricity, was submitted by S. Mc Cormick, Superintendent of lamps and gas. He stated that the resolutions of the Common Council called for 2,003 additional arc lamps, to replace 5,345 gas lamps. This statement conveys a very erroneous impression as to the efficiency of the electric lights. The records prove that they have heretofore replaced from 8 to 12 gas lamps each, according to location. The Superintendent even goes so far as to say : "I have not discovered any advantage which the electric light possesses that cannot be obtained from gas lamps, except the instantaneous lighting."

No claim in behalf of the advantages of electric street lighting, has been more generally admitted than that of the additional security it offers to life and property. No portion of the community have been more earnest in their endorsement of its practical value, than the police authorities of the different cities where electricity has been introduced. The very fact that one single petition in favor of electric lighting represented $400,000,000 capital would seem to be sufficient evidence that the city taxpayers are willing to assume the additional burden, although the extra cost is trivial.

New York is the metropolis of America and requires the most perfect system of street illumination, at any reasonable cost. Not only the principal streets, but every lane and alley ; places where daylight scarcely penetrates, should all be thoroughly illuminated. If there is any job lurking in the suspicious statement of Superintendent McCormick perhaps a beam of light turned in that direction, may unearth some interesting developments.

ARTICLES.

THE NATIONAL SELF-BINDING INSULATOR.

THIS insulator, which is now being placed upon the market, embodies certain new features which appear to be of greater practical value than any improvement made in glass insulators since the introduction of the internal screw-thread, now almost universally used in this country. This improvement enables the ordinary tie-wire to be wholly dispensed with, the insulator, with its clip, being so formed that the line-wire is readily placed in position, and rigidly secured without the aid of tools. The insulator can be applied in any position, wherever the ordinary pattern is available.

Upon the exterior of the upper portion is formed a conical and gradually expanding screw-thread, similar in shape and principle to the point of a gimlet. By the use of a rigid wire shackle or clip the line-wire is attached as shown in figure 1. The clips are prepared ready for use as shown in figure 2, the main curve being so formed as to encircle the body of the insulator at the base of the conical screw, while each end is bent into a hook, which grasps the line-wire as shown. The bell of the insulator below the resting place of the line-wire is of a form which experience has shown to be the most desirable for insulating purposes. In attaching the line-wire, the insulator is first screwed a short distance upon the pin, and the point of the screw-top inserted within the clip, which has been previously hooked over the wire at the proper point, as shown in figure 2. The outside and inside threads being led in opposite directions, two or three turns of the insulator brings it to its bearing on the pin, at the same time carrying the clip with the wire into its proper position, as shown in figure 3. A little practice enables the lineman to do this work with the greatest ease and rapidity, while the attachment is perfect in appearance and security. This ingenious and effective device is the invention of J. Slater Lewis, of Birkenhead, England. It has been used in Europe and India for some time, where it has been highly approved, and pronounced to be the only insulator thoroughly adapted to the various requirements of telegraph construction. The principal English railways and telephone companies are now using it, and after rigid tests the officers of the British post-office telegraph have decided to adopt it exclusively for all future work. It may be mentioned that the internal screw of this insulator is more perfect than any heretofore made, by reason of the use of newly-invented molding tools (patented by L. B. Gray and J. Ham, October 7, 1884), which give greater sharpness and accuracy to the thread. Thus the insulator is not only held more securely to the pin, but is more readily attached, while the loss arising from the discarding of insulators which are defective in this respect is avoided. Various advantages of more or less importance are secured by the use of this insulator. A considerable saving in new construction may be effected, as after a little experience a considerably greater length of wire may be strung in a given time by the same number of hands than by the old method. In renewing line-wire on poles its superiority is still more apparent. In replacing broken insulators, changing poles, etc., no tools of any description are required in order to transfer the wires. The discarded insulator can be unscrewed or broken to pieces in an instant, and the new one substituted without disturbing the clip or even ordinary tie-wire, if the latter be used. Where a line has been constructed with this insulator no expense for new tie-wires will be incurred in re-building, nor time consumed in removing the old ones. The same clips may be used and removed repeatedly without damage.

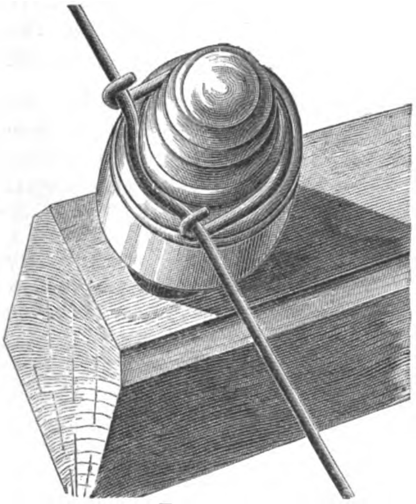

FIGURE 1.

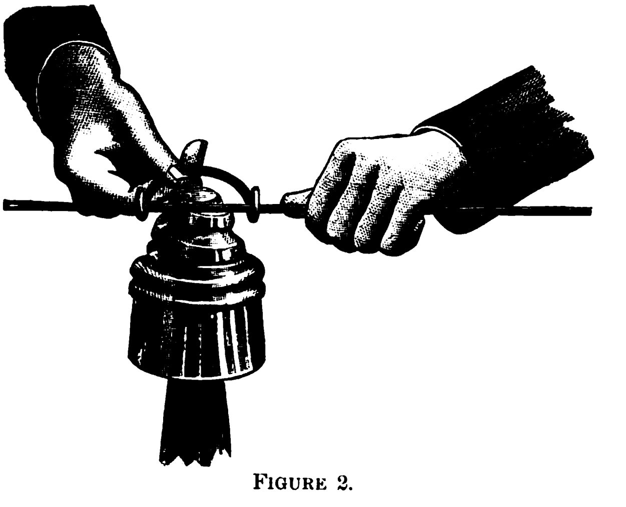

FIGURE 2.

FIGURE 3.

One of the most important points to be gained by its use is the greater durability of the line-wire, which is due to the fact that as no tools are used in making the attachment, the zinc coating of the wire is not abraded. Mechanical injuries of this nature permit the access of moisture; the iron or steel is attacked by rust, resulting in weakness and ultimate breakage. Better insulation is also secured, as there are fewer crevices to facilitate the accumulation of soot and dust, while those which do exist are open to the cleansing action of rain. By proper adaptation of the length of the clip, the wire may be held at any required degree of tightness.

The old tie-wire fastening may be used in connection with this insulator, as with the ordinary pattern. Used in this manner, it is equal in every respect to the old form, retaining, however, the important advantage of replacement, with less than half the time and labor. In order to meet every possible requirement in either building or rebuilding, these insulators are now being made in the same standard sizes as have been generally used heretofore.

HARD-DRAWN COPPER WIRE AS AN OVERHEAD CONDUCTOR.

BY WM. MAVER, JR.

IT has, of course, long been known that copper possesses electrical qualities far superior to iron as an overhead conductor for telegraphic and telephonic purposes, but these

Digitized by Google

superior qualities have not been availed of to anything like the extent they would have been had the intrinsic value of copper not been so high, its tensile strength so low, and its tendency to elongate, or "draw out" so great, in comparison with iron; three very serious and, in fact, fatal objections to its successful employment in the capacity of an overhead electrical conductor.

But the almost simultaneous demand for a better electrical conductor than iron for telephonic purposes together with the surprising fall in the price of copper, which has recently occurred, has led to the making of a great many experiments with this metal, with a view to utilizing it for the above purposes. These experiments have resulted in the production of what is now known as hard-drawn copper wire, which, it is more than likely, will prove—indeed has already proven to be—an excellent substitute for iron as an overhead conductor.

The opinion hitherto held by many with regard to the employment of copper for this purpose has been that owing to its low tensile strength and softness, it would not withstand the changeable climate of this country. This opinion was doubtless founded chiefly on the experience of Morse with his first wire between Washington and New York, which was of copper, and, as is well known, was a complete failure. In referring to this failure, Mr. James D. Reid, a contemporary of Morse, in his popular work "The Telegraph in America," cites the fact that an intelligent mechanic of New York, named B. Tucker, proposed to improve the tensile strength of the copper wire by running two strands of the metal through a die, thus drawing it "hard;" and Mr. Reid states that several miles of copper wire were thus drawn and erected on the poles, but as iron wire was then satisfactorily filling the place of copper between the above points, Mr. Tucker was not encouraged to proceed, and copper wire as an overhead telegraph conductor fell into complete disuse.

This, however, so far as I have been able to ascertain, was the first attempt to produce hard-drawn copper wire. The term "hard-drawn" has been given to copper simply as a distinguishing name. With equal propriety the iron wire commonly used for telegraphic purposes might be termed hard-drawn iron wire, for the process by which the different metals are drawn is almost precisely the same in each case; that is, they are first made into iron or copper rods and are then drawn through one die after another until the desired diameter is reached. In each case the different metals are annealed during the process of the drawing, although in the case of iron the annealing is much more frequent, and after its last drawing it is again annealed; while copper, after the last drawing, is not annealed. The cause for this is, that unannealed iron would be so hard and stiff that it would be a difficult wire to handle. The annealing process renders it softer and more pliable, and this without detracting too much from its tensile strength, in fact it adds thereto. Were copper wire similarly annealed after the last drawing it would be much too soft for service as an overhead telegraph wire. That this is the case will readily be seen when it is stated that No. 12 B. W. G. copper wire annealed has a tensile strength of only 330 pounds, while it will elongate 36 per cent. of its length. On the contrary, unannealed copper wire, namely, that which is known as hard-drawn of the same size, has a tensile strength of about 575 pounds and will not elongate more than one per cent. without breaking.

It has for a long time been supposed that an overhead conductor, to be entirely successful, must have a high tensile strength coupled with an elongating quality of at least 18 per cent. There has never been any difficulty in producing an iron wire with these qualifications, but in the past and present state of the art it is impossible to combine in copper these two requisites.

With copper we may obtain a low tensile strength and great elongation—or high tensile strength and little elongation, but not otherwise. The question has, however, arisen within the past year or two, as to what constitutes the necessity for so high a percentage of elongation in telegraph wire; and to this question no one appears to be able to furnish a very satisfactory reply.

I am aware of one prominent electrician who recommended that iron having a very high percentage of elongation and great tensile strength should be used in localities where sleet storms are frequent, in order, as he said, that the weight of the sleet should sag the wire until it touched the ground, which would thus prevent the wire from breaking; while the ice would sufficiently insulate the wire to allow of the transmission of signals almost as usual.

After the ice had melted, the wire was expected to return to its former elevation. The same gentleman stated that this plan was in vogue in the Highlands of Scotland.

Of course if a wire is to be expected to repeat the above performance on the occasion of every sleet storm, the necessity for a high percentage of elongation, and elasticity also, would be obvious, but, even granting that such an arrangement is practicable where there is but one wire on a pole, it would be quite useless where many wires are strung on one pole, as the wind would quickly cross them.

As a matter of fact, however, it is difficult to find any valid reason for requiring an elongation exceeding, say, from one to two per cent; for, in case of a weight of sleet on the wires it becomes at once a question of tensile strength.

If the weight of sleet exceeds the breaking strain of the wire it will break, whether the elongation of the wire be one or 30 per cent., always providing that the wire does not stretch until it reaches the earth, as above referred to.

Perhaps the principal reason hitherto offered for the necessity for great elongation in a telegraph wire has been that such a quality is requisite in order that the wire may withstand the contraction of the metal due to a sudden lowering of temperature; but a little calculation will show that even to meet this requirement a percentage of elongation of from one to two will amply suffice.

For instance, according to Trautwine, copper will expand or contract one part in 100.4 parts for every degree of rise or fall in the temperature. This would give, in the event of a sudden fall of, say, 130° Fahrenheit, a contraction of about 130 feet in 19 miles of wire. That is about 7 feet per mile—or, supposing 30 poles per mile, a contraction of 23 hundredths of a foot between poles. One per cent. of elongation would amount to 52.80 feet per mile, or about 1.7 feet between poles.

It should be noted here that the percentages of elongation of hard-drawn copper wire, given above, have been obtained by measuring the elongation after the wire has actually broken and hence the elongation at the point of fracture was also measured. Careful calculations, however, showed that the wire, exclusive of the fracture, elongates about .75 per cent.

Thus, without including the slack, more or less of which is always to be found between poles, the above percentage of elongation would more than meet any strain that is likely to arise from contraction due to sudden changes in the temperature.

This being true it becomes necessary to find a theory which will account for the fact that in almost every case on all newly constructed wires there are numerous breaks caused by the first sudden fall of temperature. Close observation has shown that on the average from six to ten breaks occur at such times in about every 100 miles of iron or hard copper wire. The average has been slightly less thus far in the case of copper. After the first severe frost the wires seldom break from this cause and they are then said to be seasoned.

It is a fact that in almost every instance the breaks in iron wire due to changes of temperature, occur at flaws in the metal. The theory then is, either that moisture enters these flaws and freezing therein thus breaks the wire; or, that the flaws, which generally consist of brittle or partly

Digitized by Google

honeycombed portions of wire, having no elongation whatever, break under the additional strain due to contraction.

In the case of hard-drawn copper wire the breaks that occur after a sudden fall of temperature have in almost every instance been found at bad joints or kinks. Inasmuch, therefore, as neither iron nor copper continue to break after the flaws and kinks have been disclosed by the first severe frost it would seem that the above theories are correct. These results show very clearly the necessity for the exercise of great care in the inspection and construction of telegraph lines.

Many experiments have been made with the view of obtaining a copper wire having a combination of high tensile strength and a moderately high percentage of elongation, but so far the results have not been encouraging.

It has been uniformly found in all these tests that as the tensile strength rises the elongation rapidly decreases, and this occurs whether the wire is brought to the desired diameter or size with two or three drawings, or with eight or ten drawings.

For instance in one test, of which I have a record, eight pieces of wire were experimented with, and it was found that to obtain an elongation of from 2.5 to 3 per cent. in a No. 12 hard-drawn copper wire it was necessary to reduce the tensile strength from 130 to 140 pounds.

Starting with a No. 10 (diameter 135 mils.) annealed wire and drawing it twice to reduce it to a diameter of 104 mils (about No. 13, B. W. G.) the wire showed an elongation of 23 per cent. and a tensile strength of 330 pounds, while the same wire, drawn three times to reduce it to the same gauge, viz: 104 mils, had a breaking strain of 410 to 420 pounds, and elongated but 3 per cent.

These results seemed to indicate that there is no regular ratio of increase or decrease of tensile strength with the number of drawings to which the wire may be subjected in the course of reduction to a certain size. Nor is an increase in the percentage of elongation always accompanied by a corresponding increase in the ductility of the wire, or by a fall in the tensile strength; thus a wire of 104 mils diameter has been manufactured in which the tensile strength has risen to 600 pounds, and this with a percentage of elongation of from 2 to 2½ per cent., while in the same wire there was a marked falling off in ductility.

This difficulty in combining the foregoing qualities in copper wire has, of course, led to many efforts to secure an alloy of copper and some other cheap metal, which would impart to the copper a much greater tensile strength, without at the same time detracting too much from its electrical conductivity, but up to the present time without success.

This is doubtless chiefly due to the great falling off in conductivity which is manifest in alloyed copper. For instance, calling the conductivity of pure copper 93.08 at 18° C. Messrs. Matthiesen and Holzman have recently ascertained by careful examination that the conductivity of copper alloyed with but 0.48 per cent of iron is reduced to 34.56 at a temperature of 11.2° C., while the conductivity of copper alloyed with 2.45 per cent of silver, itself a better conductor than copper, is reduced to 79.38 at a temperature of 19.7° C.

As I have already intimated, however, there does not appear to be any good reason why an overhead telegraph wire should be required to have a high percentage of elongation, and I am sustained in this view by several experienced superintendents of construction of telegraph lines. It is their opinion that a wire possessing from 1 to 2 per cent. of elongation and fairly ductile, with a tensile strength of at least 2½ times its own weight per mile, will meet all the requirements, and these views are strongly borne out by the excellent manner in which the thousands of miles of hard-drawn copper wire on the poles of the Baltimore and Ohio Telegraph Co., and many local telephone companies, have withstood the extreme changes in temperature of the past severe winter. The superintendent of a Michigan telephone company writes: "my experience with our 90 miles of No. 12 copper wire has been remarkable, notwithstanding the extreme variations of temperature we have only had one break this winter."

Of course these gratifying results have not been obtained without much care in the construction of the lines, but the results obtained have well repaid the care bestowed in this respect.

In stringing hard-drawn copper wire on the poles, the method employed by the Baltimore and Ohio Telegraph Co. has been to draw the wire up quite tight, leaving no perceptible sag between the poles, which has been found advantageous in several ways, for example it lessens the liability of the wires to swing together, and also, by limiting the sway, to-and-fro, of the wire, decreases the liability of chafing at the insulators. In addition to this it has been found by observation that the less the sag of the wire the less is the danger of the wire breaking from a weight of ice during a sleet storm, inasmuch as the rain is much more apt to drop off the wire, or be blown off, the nearer the wire attains a perfectly horizontal position between the poles. It has frequently been noticed that on badly sagged wires the sleet is much the thickest midway between the poles, doubtless due to the rain following the course of the sag and freezing as it flows.

In connection with this subject the following specifications of the Baltimore and Ohio Telegraph Co. for hard-drawn copper wire weighing 170 pounds per mile, about equal to No. 13, B. W. G., will probably prove interesting.

SPECIFICATIONS FOR HARD-DRAWN COPPER WIRE WEIGHING 170 LBS. PER MILE.

Resistance per mile	5.23 ohms at 60° F.
Weight per mile ohm	889.1 lbs.
Diameter in mils	.104
Conductivity at 60° F.	98% of pure copper
Elongation	1.25% to 1.50%
Tensile strength	550 lbs.
Twists in 6 inches	40
Bends upon itself	3½

All wire furnished to be smooth, bright and polished, round in cross-section, and without kinks or indentations of any kind.

Length of coil at least three-quarter mile without splice.

Minimum weight of bundle without packing 127½ lbs.

Weight of each bundle to be marked on accompanying tag.

After having been passed by the company's inspector, each bundle to be tied with four bands, then thoroughly covered with burlaps or sacking, and wound with 15 turns wire outside.

A few words explanatory of some of the above technical terms may not be amiss here.

By weight per mile ohm is meant the weight of one mile of wire of a certain percentage of electrical conductivity which would be required, to obtain a resistance of 1 ohm.

The weight per mile ohm is thus the product of the weight per mile and the resistance per mile; that is in the above case 170 lbs.×5.23 ohms.=889.1 lbs.

The conductivity of pure copper is generally placed at 100 and the best authorities calculate the weight per mile ohm of pure copper to be 871.177.

Thus a pure copper wire weighing 170 lbs. per mile should have a resistance of 5.12 ohms per mile.

The wire is tested for ductility by bending upon itself. For instance, pieces of the wire about 10 inches long are bent and straightened to their original positions (in the same manner, for example, as a pocket knife is opened and closed) until they break. One bending and straightening of the wire constitutes one bend on itself.

In addition to the above specifications it is required that each coil shall be rewound on a drum in the opposite direction to that in which the wire is wound during the final drawing; the object of which is to take the "spring" out of the wire. It is also customary during the operation of this last winding to cause the wire to pass through a piece

Digitized by Google

of burlaps, held in the hand of an employé, to detect any rough or splintered portions of wire. This last winding is quite an important matter as it greatly facilitates the handling of the wire during construction, and, of course, also lessens the tendency of the wire to "curl" around adjacent wires when it happens to break.

As previously stated, there does not appear to be any regular ratio of increase of tensile strength and decrease of ductility of copper wire, consequently a wire which will meet the above specifications as to tensile strength, ductility and elongation can only be obtained by actual experiments. Thus, starting from a copper rod $\frac{7}{32}$ of an inch in diameter, it has been found that to produce a wire $\frac{104}{1000}$ of an inch diameter having the desired qualities, it is necessary to give it from 12 to 14 drawings and to anneal it about four times between the drawings.

Until quite recently difficulty has been experienced in furnishing hard-drawn copper wire of any considerable length, in a continuous coil and without joints. This was owing chiefly to the difficulty in maintaining the gauge of the die a uniform size—but by means of what is known as the Cowles silver solder joint, lately patented, unjointed coils of any length are now obtainable.

This joint is made by tapering the ends of the wires to be joined, and silver soldering them. The joint is then passed through the die, after which it is scarcely discernible. Tests made of these joints for tensile strength show only a very slight falling off as compared with unjointed wire.

Careful electrical tests show that the conductivity of hard-drawn copper wire is 2 per cent less than annealed copper. Thorough chemical tests of the wire now furnished by the various manufacturers prove that it is about 99.999 per cent. of pure copper, there being only the slightest trace of impurities.

That this is true is evident from what I have previously said as to the effect of alloys on the electrical qualities of this metal.

So far as I can learn there are now in successful operation about 10,000 miles of this wire in the United States, of which from 7,000 to 8,000 miles are on the lines of the Baltimore and Ohio Telegraph Co. The remainder is on the lines of various local telephone companies, and in view of the uniform success attending its use by all of these companies, and the acknowledged superior electrical qualities of copper over iron, there can be little doubt but that hard-drawn copper wire is destined to be the principal overhead electrical conductor of the future.

TAYLOR'S ELECTRIC TELEPHONE.[1]

BY THEODORE F. TAYLOR.

In the present paper I propose to tell what I know of the telephone.

Having made alleged improvements in the art, and having been so fortunate [or otherwise] as to have obtained from this and several foreign governments letters patent for the same, it is natural that I should take pride in explaining my invention to my electrical friends.

Before going any further, however, I wish to make an announcement which may startle you all and relieve the minds of some. I do not claim to be the original inventor of the telephone. While half the states of the Union claim that honor for one of their sons, my native state of Delaware makes no such claim. I am only a gleaner in a field already harvested.

My first effort in the line of telephonic invention was made several years ago, when it occurred to me that a receiver might be constructed on the principle of the attraction and repulsion of currents. In the text-books the attraction and repulsion of currents is treated under the head of electro-dynamics,—that is: the laws of electricity in a state of motion, or the action of electric currents upon each other and upon magnets, while electrostatics deals with the laws of electricity in a state of rest.

The action of an electrical current upon another was first investigated by Ampère, shortly after Oersted's celebrated fundamental experiment. All the phenomena, even the most complicated, follow from two simple laws, which are:—

1. Two currents which are parallel, and in the same direction, attract one another.

2. Two currents parallel, but in contrary direction, repel one another.

After some study upon this theory I made my first model, and tried it in connection with an ordinary Blake transmitter.

The model consisted of two confronting flat coils of fine copper wire, cemented to two hard rubber discs, and held in a wooden case. Not obtaining satisfactory results with an induced current, I laid this model aside.

My next connection with the subject was when I was requested as an expert to investigate the researches of Philipp Reis,—to construct and operate the instruments described by him. I will here remark that at the time I began this investigation I was but slightly acquainted with the history of the telephone and the claims of rival inventors; but such knowledge as I had led me to suppose that the inventions and publications of Reis had but little relation to the invention of the modern telephone.

I constructed all the forms of transmitters and receivers described by Reis and succeeded in making them all transmit and receive articulate speech. The lectures and papers of Reis prove him to be the original inventor of the telephone. He was not only the inventor,—he fully understood the principles of their operation and construction, and he imparted his knowledge to others in the plainest language. He invented a name for his instruments. He called them "The Telephone." My feelings are strong on this subject, because I am not only indebted to Reis for instruction in the art, but it was one of his transmitters that first made my receiver talk. It has been the fashion to belittle the inventions of Reis for the reason that they failed to become of any commercial value under his hands. He was looking for scientific and not financial success.

I have never heard the great discoveries of Newton belittled for the reason that he failed to apply for a patent on gravitation.

My experience with Reis's instruments made me familiar with battery transmitters, and on connecting one up with my old model I heard it talk and was encouraged to develop it. In explaining my invention I cannot do better than quote from my application for a patent:—

"My invention is based on the well-known fact that electric currents when they are caused to traverse neighboring parallel conductors in the same direction, exert upon each other an attractive force, and when in opposite directions a repulsive force; and the degree with which they so attract or repel, is dependent upon the proximity of the conductors and the strengths of the currents. When, therefore, the positions of the conductors are approximately constant the variations in force may be considered as depending upon the variations in strength.

"Parallel results are obtained when an electric current is caused to pass through a single electric conductor in proximity to a continuation of itself.

"Upon this principle the invention is essentially based, and it consists generally, in so disposing an electric conductor that different portions of its length are brought into proximity to each other and a current of electricity caused to traverse the same will pass and repass in approximately parallel directions or in opposite directions through such different portions."

Without further explaining the principles upon which my receiver is supposed to work, I will describe in a few words some of my early experiments.

1. Read before the New York Electrical Society, April 22, 1885.

Digitized by Google

My first model consisted of two flat coils of fine wire cemented to hard rubber discs. To demonstrate the principle I then procured an old violin (which I have here), and stretched two fine steel music wires (of No. 26 gauge) over the bridge, and made the connections so the current traversed the wires in the same direction. Upon using a quantity current I found this instrument reproduced speech, although faintly. I then cemented a flat coil to an ordinary butter dish about two inches in diameter, also to glass and mica plates. Another form was made by cementing wire inside a thin glass tumbler. All these forms of receiver gave results more or less satisfactory.

When a mass of iron was brought near any of these receivers, the sound was reinforced.

When one of the coils was placed upon an ordinary flat-iron the volume of sound was more than doubled.

A coil was cemented to an iron disc, and the result was encouraging.

Then two coils were cemented to iron discs which were fastened in a wooden case. This made an excellent receiver. The attraction between these coils is quite strong. Here is an illustrative model in which one coil is fixed and the other free to move. On connecting the battery you see one coil move towards the other. With this form of receiver the reproduced speech was clear and faultless. The consonants were properly reproduced. Such words as sunset, fructify, pencil, etc., were faithfully rendered. One form of receiver was made of iron wire made into flat coils, and responded to induced currents. Another form was made of both iron and copper wires laid parallel and made into a flat coil. This was not very good.

I sought to increase the volume of sound by using large discs, but the voice sounded muffled and indistinct. My best form of receiver is now made as follows :—

Within a suitable case are supported two plates or discs 2¾ inches in diameter, which may be of metal similar to the diaphragms usually employed in the well-known form of telephones, or they may be constructed of paper, vulcanized fibre, glass, mica, wood, porcelain, or other suitable resonant material. One of the plates is perforated at its centre. The plates are separated by a thin ring of hard rubber. Upon the confronting surfaces of the two plates are placed two flat coils of No. 36 copper wire, fastened by shellac varnish, and they are connected with each other in such a way that a current of electricity entering one terminal will pass through the coils in succession, and through the convolutions of the same in parallel directions. While a steady current is flowing the two coils and plates will be attracted towards each other, by reason of the attractive force exerted by the two broad streams flowing in the same direction.

In figure 1, A represents a case of hard rubber for supporting the several parts of the instrument. This case is made in the form of a wide ring in two sections, *a*1 and *a*2, adapted to be screwed together as shown. Within the case A are supported two plates, *c*1 and *c*2. One of the plates is perforated at its centre, as shown at *f*1, and they are separated a slight distance from each other by means of an intervening ring of hard rubber, *a*3. Upon the confronting surfaces of the two diaphragms are cemented two flat coils of wire, as shown at *c*1 and *c*2 respectively.

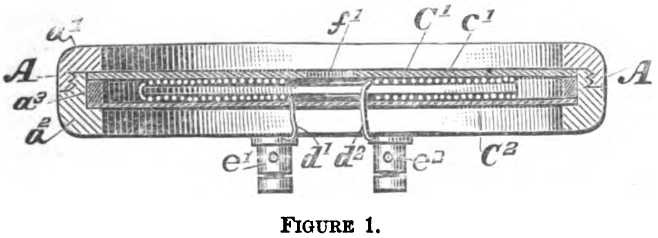

FIGURE 1.

In figures 2 and 3, two different methods of connecting the spiral coils are illustrated. According to the plan illustrated in figure 2, the current is caused to traverse both conductors in parallel directions and the two spiral coils will be attracted towards each other by reason of the attractive force exerted by the current upon itself in the several portions of the conductor.

In figure 3, an organization is illustrated in which the connections of the two coils are so charged that the current is caused to traverse the same in opposite directions and the two coils are repelled by each other.

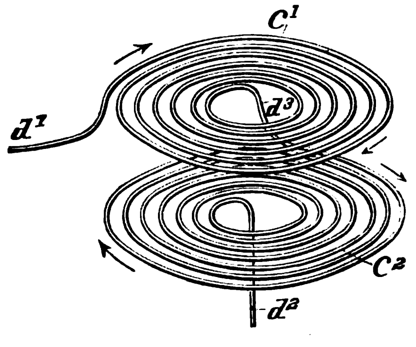

FIGURE 2.

In action this attractive force is variable by reason of the variations in the strength of the current which are caused by the action of the transmitter.

These variations cause vibrations on the part of the receiving instrument capable of producing sound waves or sonorous vibrations corresponding to those by means of which the current vibrations were originally occasioned.

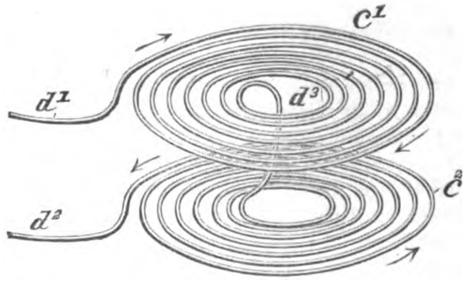

FIGURE 3.

A Hughes microphone with four contacts is used for a transmitter. The transmitter I shall use this evening has been used in my experiments for the past six months, without any adjustment, with from one to 30 cells of Fuller battery, under all conditions. On ordinary circuits, say up to two miles, four cells of Fuller battery are used at each terminal. On a 30 mile circuit measuring 400 ohms, 12 cells are necessary. In fact the battery is increased according to the resistance of the circuit and as the percentage of variation at the transmitter decreases. I will be able to demonstrate to you this evening that my telephone is about equal in loudness to the best modern magneto telephone. I think you will also find that its articulation is superior to any you have ever heard. Since it requires a battery current to work it properly, it does not respond to induced currents to any great degree; therefore it does not pick up all the neighboring currents and annoy the listener with the "frying" and crackling sounds present in magneto telephones in our large cities. For the same reason it works as well through an underground circuit as over a pole line. In fact I have the assurance to hope that I have solved the problem of underground telephony.

I will now let the instrument speak for itself.

APPLICATION OF ELECTRICITY TO HOROLOGY.

BY CHARLES A. TERRY.

(Continued from page 92.)

II.

It will be convenient to consider the subject under the following divisions:

I. Electric Clocks.
II. Secondary Dials.
III. Synchronous Pendulums.
IV. Correcting Devices.

Electric clocks, strictly speaking, include those forms only in which electricity is employed as the motive power, and the clock-movement determines and controls for itself the supply of its maintaining power. Clock movements which are actuated by currents or impulses transmitted from a primary clock are more properly termed secondary clocks or dials.

The principal classes of electric clocks are *first*, those in which a maintaining impulse is imparted to a pendulum or balance-wheel at each beat or each alternate beat, and *second*, those in which electro-magnetic devices are employed for periodically winding a spring or weight. In the first class the impulses are sometimes given by the periodic attraction exerted by a magnet or a solenoid upon an armature, the one or the other being carried by the pendulum, as in the Bain system, but usually the impulses are given by a small weight or spring which is lifted or placed under tension by means of an electro-magnet, and released by the movement of the pendulum or balance-wheel. The comments made upon both classes by Beckett in his excellent treatise[1] are somewhat discouraging to one disposed to perfect the electric clock. Allowance, however, must be made for the author's obvious predilection for mechanical clocks, and consequent aversion for an interloping power in the form of electricity. Referring to the Bain system he remarks, "Nor would anything but the strongest evidence, independent of the inventor, convince me that any independent pendulum directly maintained by electricity can succeed in keeping good time for any considerable period." In speaking of the Shepherd clock, to the pendulum of which periodic impulses were imparted by a small gravity-arm lifted through the influence of electricity and allowed to fall on a pallet, like the down-pallet of a dead-escapement, Mr. Beckett adds, "but unfortunately it did not always lift, and any one who sets to work to invent electrical clocks must start with the axiom, that every now and then the electricity will fail to lift anything, however small." Notwithstanding these dire predictions many inventors have appeared, who, fully convinced of the practicability and utility of electric clocks, have cultivated the field until a result has been attained which would withstand Mr. Beckett's severe test without difficulty.

The Shepherd clock, above referred to, was shown at the London exposition in 1851, having been invented some two years before that time. It was first proposed to give the impulses by a spring wound by an electro-magnet and retained by a detent. The pendulum rod carries two pallets, one of which raises the detent and the other receives the impulses of the spring. The circuit through the magnet is completed by the pendulum at the extremity of its vibration to the left and the impulses are given at the extremity of the vibration toward the right. The pendulum is thus merely a measurer of time and a circuit-controller, and the amount of force imparted to it is independent of the battery strength. When a weight is employed the arrangement is similar.

An interesting form of clock, which appeared soon after this, is that invented by Prof. M. G. Farmer, then of Salem, Mass., about the year 1852. The principle of this clock is similar to that of the Shepherd clock, that is to say, equal impulses are imparted at regular intervals to a vibrating pendulum by the aid of a spring and an electro-magnet. Figure 2 illustrates the principle upon which

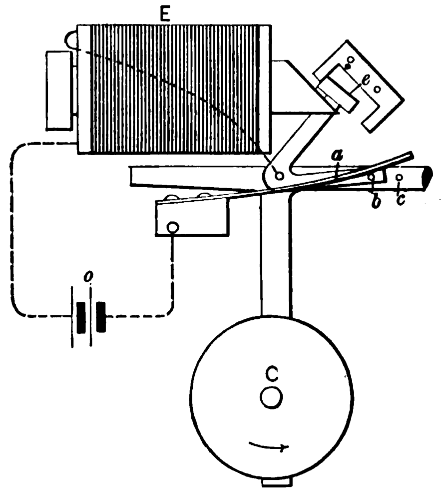

FIGURE 2.

the clock was constructed. The circuit of a battery o is closed through the magnet E by means of an impulse-spring *a*, and a lifting-pawl, *b*, carried by the armature, *e*. The electro-magnet being vitalized, the spring, *a*, is raised. The pendulum, c, by its swing toward the right hand carries a pin, *c*, attached thereto, against the impulse-spring, *a*, thus raising it out of contact with the lifting-pawl. The circuit of the battery, o, through the magnet, E, being thus interrupted, the armature and lifting-pawl fall away and the impulse-spring is free to press against the pin, *c*, and to aid the force of gravity in causing a return movement of the pendulum. In its descent the impulse-spring again comes into contact with the lifting-pawl, *b*. The circuit being thus again completed, the spring is raised and remains under tension until the operation is repeated at the return beat of the pendulum.

So great was the promise of this clock that Prof. Farmer obtained, in 1853, a charter to establish an electric-clock system in Boston. Unfortunately, however, his many other interests, especially the development of the fire-alarm telegraph, which taxed his time and energy to the utmost, prevented him from then devoting sufficient attention to the project to carry it into active operation.

It is interesting to notice to how great an extent this general form of clock found favor with other inventors. In 1854, Alexander Hall, of Ohio, invented a clock in which maintaining impulses are imparted to the pendulum near its axis of oscillation by a spring attached to the end of a horizontally vibrating lever. The lever carries two armatures, one upon each side of the pivot. Two electro-magnets act alternately upon the respective armatures, causing the lever to move in a horizontal plane, somewhat in the manner of a walking-beam. The circuit connections are controlled by the pendulum, while the movements of the lever give motion to the clock and at the same time furnish maintaining power to the pendulum. Mr. Hall further proposed to place secondary clocks in circuit with one of the electro-magnets and it is evident that the regularly recurring impulses would serve very well to drive the secondary clocks.

In 1863, Messrs. Hamblet and Edmands, of Boston, devised an ingenious method of completing and interrupting the circuit of the magnet which controls the impulse-spring. In this clock, like Shepherd's and Farmer's, the force of the impulse was not dependent upon the strength of the battery, it being requisite only that this should be sufficient to cause the electro-magnet to attract its armature.

An application of the equal-impulse idea to balance-wheel clocks was made by Robert Wear, in 1847, and by

1. A rudimentary treatise on Clocks, Watches and Bells, by Sir Edmund Beckett, Bart., London.

Digitized by Google

Vitalis Himmer, about 1869. A spring moves the balance-wheel in one direction and an arm extending from an armature-lever acts counter to the spring. The movement of the balance-wheel controls the connection of the circuit through the electro-magnet. D. F. Sweet, of Michigan, and Elijah Clark, of Kentucky, several years later, devised other methods of applying the principle to balance-wheels. Much the same form of mechanism as was employed in his balance-wheel clock, Mr. Himmer adapted to a pendulum clock. The impulses, however, were imparted by small weights suspended by flexible cords. Later, Mr. Himmer made some important changes and improvements in this form of clock, one of which was to impart an impulse to the pendulum upon opposite sides alternately, thus rendering its vibration uniform. This is doubtless a much better plan than to impel it from one side only, for not only does it secure a more uniform vibration causing the amplitude to be the same in each direction, but it is more economical of power.

Among the many devices which now followed for imparting the impulses and for actuating the clock movement there should be mentioned that of Wm. M. Davis, of Cincinnati, Ohio, who, in 1871, invented a clock of the equal-impulse type, in which two pendulums are employed, one serving to control the circuit-connections and the other to impart the impulses to the first and at the same time to drive the clock-mechanism.

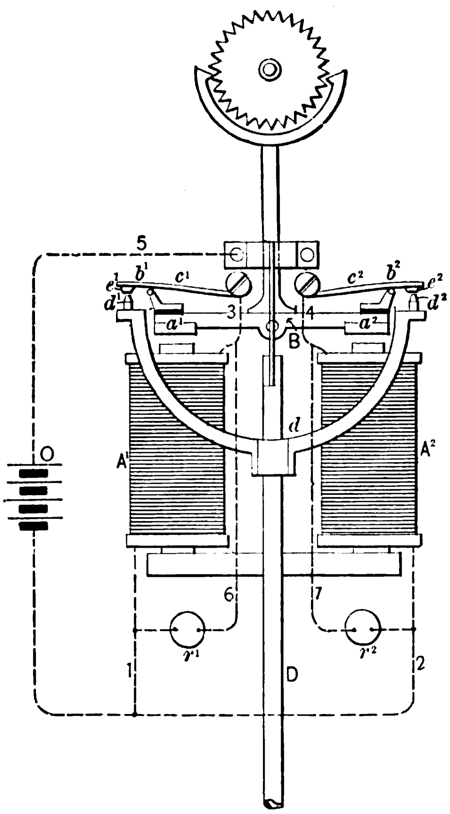

FIGURE 3.

In nearly all the clocks the impulses are imparted either each second or every two seconds. Some inventors, however, for instance, John Happersberger, of Ohio, proposed to impart the maintaining impulses once each minute. This he accomplished in 1879 or 1880 by mounting upon the pendulum rod a toothed-wheel carrying a circuit-closing pin. The wheel is revolved step-by-step by the vibrations of the pendulum and once in each revolution it places the pin in position to complete the circuit by being carried between two contact-arms. An impulse is thereupon given to the pendulum from a spring placed under tension by the action of the magnet.

It is quite impracticable to even refer to all the different modifications in which this method of actuating clocks presented itself, but having indicated the general lines pursued, it will be sufficient to mention particularly the clock which now promises to prove entirely satisfactory in its operation and especially suited to be employed as the regulator of an electric-clock system. This is the clock now in use by the Time Telegraph Co., of New York, and it is constructed essentially upon the plan proposed by A. S. Crane, of Newark, N. J., but somewhat modified by C. H. Pond and H. L. Bailey, of New York. This clock involves the giving of an impulse to the pendulum at each beat; the accomplishment of the same in such a manner that the force of the impulse is always the same; an arrangement of contact-points which not only insure good electrical connections but also afford little opportunity for irregularity in the imparting of the impulses; and finally an organization of circuits adapted to reduce the liability of the occurrence of sparks or electric discharges at the contact-points. The diagram, figure 3, will serve to illustrate the principle of this invention. Two electro-magnets, A1 and A2, are included in branch conductors, 1 and 2, leading from a battery O. A lever, B, carries the respective armatures, *a*1 and *a*2, of the magnets. A conductor, 3, leads from the magnet, A1, to an insulated impulse spring, *c*1, and a conductor, 4, leads from the magnet A2 to a similar spring, *c*2. Upon the pendulum, D, there is carried a cross-arm, *d*, which is connected with the battery, O, by a conductor, 5. Each spring carries a knife-edge contact, *e*, and these are respectively applied to two similar contacts, *d*1 and *d*2, upon the arm, *d*, the faces of the same crossing each other at right angles. The movement of the pendulum causes either the contact, *d*1 or *d*2, to strike its corresponding contact, *e*1 or *e*2, and the corresponding magnet becomes vitalized. When the magnet, A1, is thus vitalized, the armature, *a*1, is drawn down and an insulated lifting-pawl, *b*2, carried on the lever raises the spring, *c*2. This spring remains thus under tension until the swing of the pendulum in the opposite direction brings the point, *d*2, against the point, *e*2. At the moment of this contact or else immediately before, the point *d*1 leaves the point *e*1. The circuit is thus transferred from the magnet A1 to the magnet A2, and the lever is thus tipped in the opposite direction. The spring, *c*2, acts then through the contacts *e*2 and *d*2, to impel the pendulum back, and meanwhile the spring, *c*1, is raised, preparatory to imparting its impulse when the pendulum has completed its vibration in that direction. Small artificial resistances, *r*1 and *r*2, are usually included in conductors 6 and 7, leading around the coils of the electro-magnets for the purpose of allowing the magnets to discharge readily and to prevent sparks at the contact-points.

It will be noticed that in the clocks thus far considered a spring or a weight is placed in position to act through the agency of electro-magnetism; in other words, power derived from the electric current or impulse is temporarily stored up in a mechanical form. Upon reflection it will be evident that there are other ways of employing the power than by imparting impulses to the pendulum, as for instance, by applying it to the clock-train and controlling the movements of the latter by a mechanical escapement. That is to say, the spring or weight may act precisely as in a mechanical clock, being wound or placed under tension by electricity. A very good example of this is found in the clock of W. D. Whalen, of Michigan, which was patented about three years ago. A clock or watch-spring has its outer end attached to a ratchet-wheel and its inner end to the arbor of the scape-wheel. An electro-magnet which is vitalized at each alternate beat of the pendulum, acts through its armature-lever and a driving-pawl to advance the ratchet-wheel, thus carrying forward the outer end of the spring and winding the same. Meanwhile the inner end of the spring is allowed to advance by the movements of the ratchet-wheel, thus tending to unwind the spring, but the winding keeps pace with the unwinding and the

Digitized by Google

spring having at first been placed under tension, there will always be sufficient actuating power stored in the spring. It is obvious, however, that any failure on the part of the electro-magnet to actuate its armature must result in a diminution of the power stored, which could not be regained if the clock were constructed to wind the spring with the same rapidity with which it unwinds, and after a few such failures the clock would necessarily stop. This element of weakness appears to have been discovered at a very early date, for in an English paper, the Bath and Cheltenham *Gazette* of May 1st, 1844, there was published a description of a "Remontoir Electrical Clock," from which the following is an extract:—

"A galvanic clock of novel and complete character has just been completed by Mr. Wadham, of the Abbey Green, for a gentleman in the neighborhood of this city. A small 'Smee's battery' appears sufficient to maintain the clock in action for many weeks, a fresh charge of diluted acid being given once in about 14 days. The clock is put in motion *manually*, by the action of a lever on a coiled spring. It is the office of the galvanic current to continue this motion. The current periodically vitalizes an electro-magnet which, acting upon the armature, advances a ratchet-wheel. The revolution of the ratchet-wheel imparts power to a spring, which not only sustains the original impulse given to the machinery but *accumulates* it. This accumulated power, whilst provision is made for its never exceeding a certain amount, subserves two or three valuable purposes:—The varying power of the battery (provided it supplies enough to maintain the original momentum) does not affect the time-keeping; neither is it of any consequence if the accidental presence of a particle of dust at the contact-former prevent the contact being made regularly every second; and, lastly, the clock is so far *rendered independent of the battery itself* that it will continue to go correctly for above a minute *after the battery is removed;* thus providing ample time to change the battery or to renovate it by a fresh charge of diluted acid. In short, this beautiful piece of apparatus scarcely leaves anything to be desired in the construction of a galvanic clock."

The correspondent, however, seems to have been over-sanguine in his estimation of this clock, judging from the number of inventors who have since labored in the same direction, and many different ways of storing and applying the power were presented before the invention of Whalen's above referred to, some applying the circuit controller to a pendulum, others to some moving portion of the clock train and still another by bringing the battery into operation periodically. This last invention referred to is that of J. W. Wignall, of England. The descent of the clock-weight to a certain point sets free a catch which, in one instance, causes the zinc plates of the battery to drop into the solution and in another instance the solution to rise about the plates. In either case the winding of the weight immediately commences and at its completion the parts resume their former relative positions.

The only remaining clock which it comes within the province of the present article to describe is that recently patented by Chester H. Pond, of New York. This is very ingenious and withal a very complete device adapted to be operated either as a primary electric clock or a secondary clock or dial. The fundamental point of difference between this and earlier forms of clocks of the character last considered, lies in the employment of an electric motor having a rotary armature for accomplishing the winding instead of the usual reciprocating or hinged armature. The train is provided with a device which completes a circuit through the motor once an hour, and this circuit remains completed until the spring, which is capable of driving the clock for something more than an hour, is fully wound, whereupon the circuit is interrupted and the clock continues to operate in the manner of any ordinary clock for the next succeeding hour. The advantages of employing the rotary motor are obvious, for instance, the movement being constantly in one direction there is no lost momentum when once it is started, and again the rapidity with which it winds the spring is another desirable feature. The application of this class of motor, obvious as it would seem in view of what had already been done, appears to have been entirely overlooked by all the other inventors, but by its means Mr. Pond seems to have more nearly approached the ultimate solution of the general problem than any of his predecessors.

THE CONSTRUCTION OF LINES FOR ELECTRIC CIRCUITS.

BY THOMAS D. LOCKWOOD.

(Continued from page 125.)

If poles are strong enough to do their work, and if good wires are employed there is little danger of wires breaking across a highway; but at the same time it is wise to avoid all unnecessary crossings as accidents will happen, and a sharp frost or a heavy sleet storm may break down the best of lines. In some countries this is regarded as such an important point, that oblique crossings are not permitted at all, and where crossings are absolutely necessary, the poles on the opposite sides of the road are required to be immediately opposite one another. This seems to be rather an excessive caution.

Another question to be considered is the height of poles. Through the country for a line of but few wires—say one to six, a 25 foot pole seems to be quite long enough, and a good rule is to make 20 feet the minimum distance between the lowest wire and the ground. If the poles have to be set unusually wide apart, it will be better to add a couple of feet to the length as the dip at the centre of the span will be considerable. In cities, and at road or railway crossings as also where there are trees, the length will necessarily depend on the surroundings, and the judgment of the constructor must here be called into play. It is good practice to avoid sudden extremes in passing from long to short poles or vice versa, and the rise or fall should be made gradual so as to present a symmetrical appearance.

How many poles should be used per mile? This again depends absolutely on the conditions to be complied with. For one or two wires through a straight and clear section of country I would not use more than 25 poles to the mile, while if the surface of the country is rolling, and the curves and crossings abundant, it may be necessary to increase to as high a number as 35 to the mile. The average number throughout the country is probably about 30 to the mile. Ordinary poles such as these, should never have a less top diameter than five inches, and the longer a pole is the stouter it must of course be.

POLE SETTING.

Supposing now that the line of route is decided upon, and the poles purchased and prepared; the next thing is to have them delivered and distributed. If the line is to have 25 poles to the mile, a pole must be dropped about every 70 yards. If men are plentiful, it may be well to have one set of men go ahead to dig the holes, while another squad follows close to do the planting. It may seem to be a very simple thing to dig a hole properly, but none the less it is one of those minor operations which have to be more closely watched than greater ones. Not long since a case came under my notice wherein it was found that after a section of line was built by contract, the poles, which were at least 30 feet high, were planted in holes scarcely two feet deep; a circumstance which proves that even a hole for a telegraph pole should not be trusted to a contractor. Holes should always be dug with their length in the line of the wires, so that the smallest part of the loose earth after filling the hole, shall be in the line of lateral strain. If work is let

Digitized by Google

out to contractors, a proper inspector should in all cases be present to see that it is properly done. How deep then should poles be set? I should say, under no circumstances to a depth less than five feet. I am aware that it is customary to make four foot holes serve for 25 or 30 foot poles, but it is not good practice. A hole five feet deep will do for all poles 35 feet long or under (of course for temporary work, no such depth is essential), and as the poles increase in length the holes should increase in depth. All poles before being set should have a mark put on them a definite distance from the butt end, so as to indicate when set the depth of the hole.

In digging, the tools which are found the most universally convenient, are the pick, the ordinary shovel, the spoon shovel, the digging bar; and in some localities where the soil is soft and friable a variety of spoon like a short funnel, or a suction pump bucket is also very useful. This, as well as a two bladed scoop or spoon, rigged up with a swivel, ice-tongs fashion, are much used in the south. Through a rocky country, blasting appliances are also found necessary. In addition to all these, where the soil is light, time can often be gained by using a boring tool, or post auger. This tool has a cross handle and is worked by two men who walk round pushing the handle in front of them. To work it easily it must be lifted out and cleared of the loose earth, quite frequently. It has also the additional disadvantage that it cannot be worked near a wall or fence, but needs a clear sweep for the operators to work, but it makes a nice compact hole. Holes must be kept as near the size of the pole butt as possible, but if deep, may be widened in one direction—that of the line—at the surface, or even dug in steps on one side, but this is simply a concession for the sake of greater ease in setting the pole. On the whole my individual preference is simply for the pick, shovel, digging bar and spoon. Poles of ordinary size can easily be lifted into the holes; but for very large ones, a shears or derrick is required. As soon as a pole is placed in the hole, it must be turned round, to the position it is required to stand in; if only brackets are attached, these should be on the side away from the road. If crossarms, they should be sighted so as to stand directly at right angles to the line of the roadway.

At crossings, curves and corners, the pole must be so twisted, that the strain of the wire will press against the pole and not away from it. Wherever the roadway is straight, the pole may and should be set quite upright, but on curves, they ought to be set a little aslant so as to lean back against the strain.

The next thing to consider is the "tamping" or as they call it in England, the "punning." This is another of the minor operations which is often done carelessly, but which really demands great care.

Only a little of the earth should be thrown in at once, and this is to be well tamped before any more is to be put in. Stones put in the hole close to the pole aid in supporting it. On the faithfulness exhibited and care expended in tamping, the permanency of the line in a great measure depends. The earth ought to be banked up round the pole, as this prevents the formation of depressions which would tend to hold water, at the earth line. It is always well to let the poles stand a while and settle, before the wire is strung, because their strain tends to pull the pole out of place.

LIGHTNING RODS AND LEAKAGE CONDUCTORS.

In some parts of the country, lines are when unprotected, continually exposed to danger from discharges of lightning. In such districts, the poles are fitted with lightning rods, which extend 18 inches or two feet above the top of the pole. No. 8 galvanized iron serves very well for this purpose, and it can be fastened directly to the pole by strong staples. Figure 10 shows the general arrangement adopted, which is found to answer well, although the side extensions, or branches to the insulators are only used on a few poles on both sides of a station.

The best way to make earth for these rods when they are used, is to procure a sheet of galvanized iron and thread the No. 8 wire, through holes prepared in it, soldering the connections thus formed at each hole, and then before putting any earth in the hole, bending the plate so as to form a loose sleeve around the pole, of considerable surface.

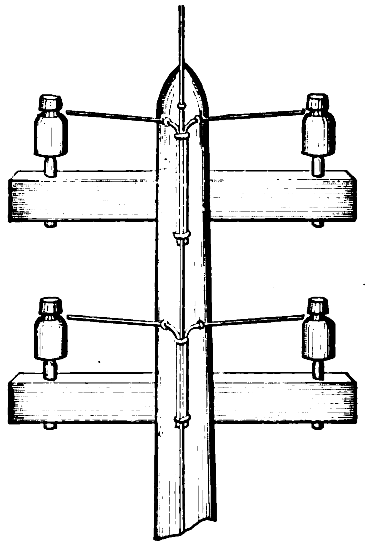

FIGURE 10.

This can be still further improved by letting a loose leaf of the iron sheet lap over the bottom of the hole, so that the iron not only surrounds, but is also under the pole when set. In ordinary soil a good earth plate is thus made.

In England almost every pole is furnished with an earth wire, arranged as shown in figure 11.

The rod is attached to the pole before it is set, and the ground end is formed into a flat helix or volute placed under the foot of the pole. I have measured the resistance of both of the earth connections which I have here described and have found the plate to be uniformly the lowest. In addition to the use of these devices as lightning guards, they have still another use. It is quite impossible especially in wet weather to so insulate wires, that no electricity shall escape from them. When two or more wires are stretched on the same poles, whatever current escapes from any of them, will of course divide itself among the routes open to it. The several routes, are first, by the pole itself direct to earth; and second by the way of the other wires to earth at other points. Now the portion escaping via the pole, does not cause any special inconvenience, as its only result is to weaken the signals on the leaky wire; but the portion which escapes on to the other wires sometimes proves a great nuisance, as it interferes with the signals passing over them. Much of the so-called "induction" on telephone lines is due most certainly to absolute leakage, and when this leakage is heavy, the contact conductor or earth wire is useful and its function is to intercept the leakage and conduct it direct to earth.

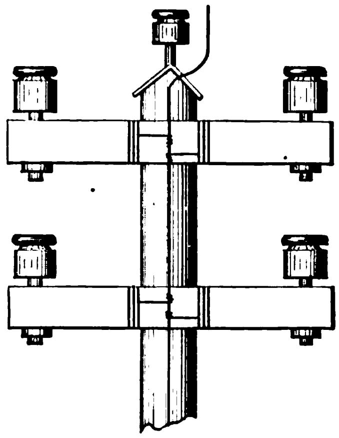

FIGURE 11.

On short telephone lines—say for those not exceeding 15 miles in length, this device has proved useful. For longer circuits the capacity of the lines is so increased that retardation due to static induction is plainly perceptible, being due to the near proximity of the earth, which by means of the rods is virtually brought close up to the line-wires. Therefore, while under certain conditions the earth wires are advantageous, I do not advocate their employment, except when rendered necessary by the prevalence of lightning storms. Moreover, unless a good ground can be obtained, it is far better to have none; because if a rod of metal runs down a pole, and does *not* make good earth, it only operates to attract the atmos-

Digitized by Google

pheric discharge, which, finding difficulty in passing off, destroys the pole.

So far as the use of the rod as a contact or leakage conductor is concerned, it would seem that the method of preventing interference between conductors by carrying the interfering currents to earth, is but a makeshift, and we fully agree with Pope in his opinion written years ago, that "a much more economical and effective method of obtaining this result, is that of improving insulation." Poles as well as housetop fixtures, need guying against any side strain, such as occurs at corners and on sharp curves. For a line of from one to six wires, a guy or stay wire should be composed of about three No. 8 iron wires, and the distant end of the guy may be fastened to a tree if one is convenient, or to any adjacent fixed object.

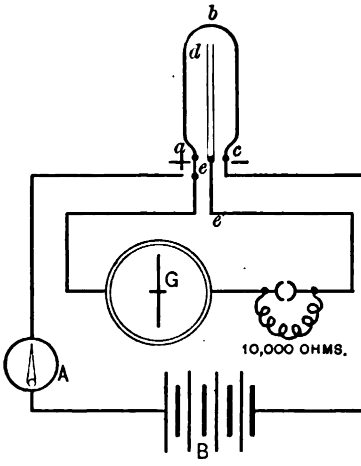
(*To be continued.*)

ON A PECULIAR BEHAVIOR OF GLOW-LAMPS WHEN RAISED TO HIGH INCANDESCENCE.[1]

BY WILLIAM HENRY PREECE, F. R. S.

1. During my recent visit to America (October, 1884) Mr. Edison showed me a very striking experiment with glow-lamps, the principle of which he had not threshed out, although he had attempted to apply it practically to the regulation of the current flowing in electric light circuits.

Fig. 1



If *abc* be the incandescent filament of a glow-lamp, *de* a thin narrow platinum plate fixed between the limbs of the filament with an independent wire connection *ee'* sealed in the glass globe, then, if a galvanometer G be connected between *a*, the positive electrode, and *e*, a derived current will be observed to pass through G, and through the rarefied space *ec* when the main current is increased to a certain strength, and the filament reaches a certain degree of incandescence. The strength of this derived current will increase with the increased brilliancy of the flowing filament. Mr. Edison made for me several lamps of different forms and character to enable me to investigate the phenomenon more carefully in England, and I have the pleasure of submitting the results of those experiments to the society.

2. I used 60 Faure-Sellon-Volckmar cells freshly and fully charged up at each series of experiments. The current through the filament was measured by a specially constituted and calibrated Ayrton and Perry direct-reading spring ammeter. The galvanometer in the shunt circuit was a sensitive tangent galvanometer of the post-office pattern. The current through the filament was regulated by varying the number of cells. The current and electromotive force through the shunt *ae* were calculated by the following method :—The resistance of the galvanometer G was 1070 ohms, and a variable resistance R was inserted in its circuit. When the current from a standard Daniell cell (1·07 volt) is sent through the galvanometer, we get a tangent reading *d*, which, since $\frac{1·07}{1070} = ·001$, is the deflection, or tangent reading corresponding to 1 milliampère of current. The deflection (d_1) given by the shunt current was first read without any resistance being inserted.

Hence

$$C = \frac{d_1}{d} \text{ milliampères.}$$

Resistance was then added and a second reading d_2 taken ; then the resistance *r* of the shunt is obtained from the formula

$$r = R \cdot \frac{d_2}{d_1 - d_2} - G.$$

The electromotive force producing the current is

$$E = Cr.$$

The shunt circuit includes the rarefied space *ec*, and it is the resistance of this space that we desire to know.

All the observations were simultaneously made by different observers. While one observed the behavior of the lamp, another read the current flowing through the filament, a third read the currents in the shunt, a fourth varied the electromotive force, and a fifth recorded the results. The electromotive force of the cells was carefully measured before and after the experiments. No photometric measurements were attempted.

3. *Experiment* 1.—The connections were made as shown in figure 1. The lamp (No. 4) was a short (75 mm.) filament lamp, with a platinum plate 30 mm. long and 5 mm. broad.

EXPERIMENT 1.

Filament.			Shunt.			Remarks.
Volts.	Ampères.	Calculated resistance (hot).	Calculated E. M. F.	Current in milliampères.	Resistance.	
		ohms.	volts.

59·94	1·08	55·50	16·2	1·80	9,000	
62·16	1·13	55·01	13·5	2·70	5,000	
64·38	1·20	53·66	11·95	3·85	3,000	
66·60	1·24	53·71	7·45	5·25	1,400	Blue effect brilliant.
68·82	1·24	55·51	10·00	5·00	2,000	
71·04	1·30	54·65	9·10	6·00	1,300	
73·26	1·35	54·28	6·50	5·00	1,300	
75·48	1·35	55·92	9·35	5·50	1,700	
77·70	1 41	55·12	9·60	6·00	1,600	
79·92	1·47	54·38	9·80	7·00	1,400	
82·14	1·60	51·34	critical point			Deflection too unsteady for observation. Blue effect very brilliant.
84·36	1·60	52·74				
86·58	1·58	56·59				
88·80	1·56	57·00	50·6	2·20	23,000	
91·02	1·58	59·30	62·5	2·50	25,000	
93·24	1·57	59·40	61·0	3·20	19,000	
95·46	1·60	59·51	95·0	3·80	25,000	
97·68	..	..	..	..	..	Filament broke. Interior of globe and faces of plate blackened.

The variation of the current and the increase in the resistance of the filament towards the end of the experiment, together with the behavior of the shunt, are very noticeable. It is quite clear that when the electromotive force attained 82 volts, a critical point was reached. From that point the current in the filament remained very steady, but the resistance gradually increased. The shunt increased

1. From the Proceedings of the Royal Society, March, 1885.

Digitized by Google

in resistance enormously, and the current through it diminished, although the electromotive force increased very largely. It is remarkable how steady the electromotive force in the shunt remained until the critical point was reached, when it suddenly increased and only reached that of the main current at the point of rupture of the filament. Again the current, which steadily increased until the critical point was reached, then diminished, indicating a considerable increase in the resistance of the rarefied space *ec*. In one subsequent experiment, after the critical point was reached, no current could be obtained through the shunt.

The direction of the current is shown in the figure.

Towards the end of the experiment, when the characteristic diffused blue effect in the globe was very marked, a bright arc was observed to be playing about the bottom of the limb at *c*, and it was quite clear that a bridge of conducting material was formed between *e* and *c*, which, together with the galvanometer, made a shunt to the filament.

This experiment was repeated upon different lamps, and the results were so similar that it is not necessary to reproduce the observations.

In all cases an intimate connection was observed between the blue effect and the appearance of the shunt current.

4. One of Mr. Edison's assistants showed me, in Philadelphia, that while the effect was very perceptible when the connections were made as shown in figure 1, *a* being in connection with the positive and *e* with the negative pole, no shunt current or a very slight one could be observed when the direction of the current was reversed. I did not find this invariably the case. One lamp (No. 8) only—a long filament lamp (150 mm. long)—which gave a marked shunt current and the blue effect, when the connections were made as in figure 1, failed to give any current or blue effect when the current was reversed within the limits of the electromotive force at my command. Doubtless I should have got both effects if I could have raised the electromotive force. In all cases, however, the effects appeared sooner and were more marked when the connections were as shown in figure 1 than when the direction of the current was reversed. The effect of placing the galvanometer between *e* and *c* was the same as reversing the current.

5. As the effect might be due in some way to the material of the conducting plate, *de*, inserted between the limbs of the filament, Mr. Edison made for me lamps with copper, iron, and carbon plates.

The following experiments were then made, the connections being the same as figure 1 :—

100	·79	126·6	19·0	3·80	5,000	Faint blue.
110	·90	122·2	..	needle hard over	..	Strong blue.
90	0·67	134·3	29·9	0·88	34,000	Reversed the current through the filament and repeated the experiments.
100	·79	126·6	17·2	3·32	5,190	Faint blue.
110	·90	122·2	..	needle hard over	..	Strong blue.

No marked difference was thus observable.

If we examine the shunt current when the faint blue tinge appeared, it was : with carbon, 3·42 ; with iron, 5·85 ; and with copper, 3·80 milliampères.

6. It might be affected by the extent of surface of the metal plate, therefore lamps were made with a plate of fine wire, and also of a very broad surface, but no difference was observable between these and the normal plate used.

7. Lamp No. 9 was made with a double platinum plate, thus (see figure 2):

Fig. 2

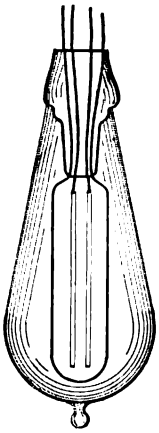

Fig. 3

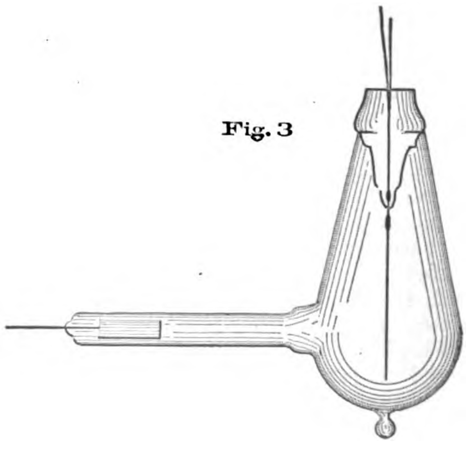

The following experiment shows that no perceptible difference was observable:—

8. Although the maximum effect was produced by Mr. Edison when the plate was fixed between the limbs, he obtained a current when it was fixed in any part of the rarefied space. If the effect was due primarily to the Crookes effect, or to the projection of molecules from the carbon filament on to the metal plate, since this bombardment takes place in right lines, we ought to have obtained effects when these lines were projected on the plate, but no effects when they could not strike the plate. Several lamps were made which are shown in the different sketches.

9. The metal plate was taken from between the limbs of the filament, and placed at the end of a tube which had a portion of the filament exposed to the plate.

EXPERIMENT 6.—NO. 5 LAMP.

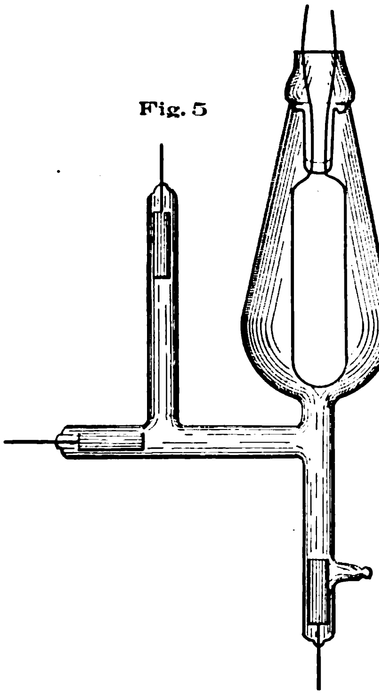
12. Professors Liveing and Dewar ("Proc. Roy. Soc.," March 9, 1882) observed a "sort of flame" during high incandescence, showing by its spectrum the presence of car-

Digitized by Google

bonic oxide. It was strongest about the junction of the carbon thread and the positive electrode. It was, according to them, the glow of the positive pole attending a discharge in rarefied gas.

It is a common thing with glow-lamps, which have the heels of the filament close together, to have an arc forming across when the electromotive force at the terminals is too high. Hence in recent lamps requiring 100 volts, Mr. Swan has considerably increased the distance between the electrodes. Moreover, whenever the incandescence of the filament is raised beyond a certain limit, the interior of the glass envelope is blackened by a layer of carbon, which has been deposited by a Crookes bombardment effect. When the carbon filament is fixed on copper electrodes, the interior of the glass sometimes becomes coated with copper as well as with carbon, and the line between the two is perfectly marked, showing that the bombardment takes place in right lines. Experiments show how very high the electromotive force can be carried, if it be steadily and rapidly increased, before the filament is broken; but practice shows that when once the blue effect appears, destruction is only a question of time. Hence the blue effect is an indication of the advent of disintegration, and a very useful warning of danger ahead.

Fig. 5



13. Now it is clear that we have a combination of the phenomena above described in the Edison effect. A continuous bridge of molecules is formed between the junction of the carbon filament and the metal plates inserted between its heels. They are found deposited on the metal plate. A shunt is thus formed whose resistance is measurable, and a definite current passes. This shunt is formed just where the negative metallic connection joins the heel of the carbon filament, as we should expect from the investigations of Mr. Crookes. The current is, however, weak and variable, and it is scarcely reliable enough to be useful for practical purposes, as was hoped by its discoverer. When the critical point is reached the blue glow and flame seem to pervade the whole bulb, and the arc-like effect, instead of playing about the heel, surrounds, apparently, the whole filament. The result is that the current passes through the galvanometer and through the rarefied space. This is clearly shown in experiment 1.

14. It is quite clear that the critical point is reached when the filament commences to be disintegrated by the projection of its molecules from its surface. It is here that the resistance of the filament commences to increase, and the law of radiation and light emission ("Proc. Roy. Soc.," No. 229, 1884) commences to be departed from, as was shown by me in a paper read before the British Association at the Montreal meeting.[2]

15. It is very evident that this Edison effect is due to the formation of an arc between the carbon filament and the metal plate fixed in the vacuous bulb; that this arc is due to the projection of the carbon particles in right lines across the vacuous space; and that it makes its appearance earlier, and is more strongly marked, when the connections are as shown in figure 1 than when they are reversed, because, as Mr. Crookes has pointed out, the projection proceeds from the negative to the positive pole, and it would commence at the point of least resistance. Its presence is detrimental to the life of the lamp, and as its appearance is contemporaneous with the blue effect, the latter is a warning of the approach of the critical point, and a sure indication that the electromotive force is dangerously high. It is also clear that as the Edison effect is only evident when we are "among the breakers," it is not available for practically regulating the conditions of electric light currents as its ingenious discoverer originally proposed.

FRENCH TELEGRAPH WIRES.

The French telegraphic system is constructed almost exclusively with galvanized iron wire of 3 mm., 4 mm., 5 mm., and 6 mm. in diameter. The 3 mm. wires are used in the construction of the "departmental" lines; the 4 mm. wires, which are the most frequently employed, serve for the long main lines of communication; the 5 mm. and 6 mm. wires are employed to connect Paris with certain large towns, and with the frontier and foreign capitals. The conditions under which these wires are accepted by the government engineers and which include tests of their electrical and mechanical resistance, of the thoroughness of their galvanizing and of their tensile strength are determined by an official schedule. The wires most extensively used, are furnished by the works of Messrs. Paul Jamin & Co., of Eurville, the Société des Forges de Franche Comté, and the Société de Comneutruy-Fourchambault. The following tables give the various coefficients for these two series of wires :—

2. In this paper I pointed out from experimental data that the light emitted by a glow-lamp varied apparently as the sixth power of the current. I verified this law, not only by subsequent experiments of my own, but, which is much more satisfactory, by experiments of others. Professor Kittler, of Darmstadt, and Captain Abney made, independently of each other, most careful and exhaustive measurements in this direction. I tabulated and traced them out in curves. They fully confirm the law that

$$L = kC^6,$$

but within limits, and that these limits embrace the ordinary range of a glow-lamp when used for artificial illumination. As long as the resistance and the current vary uniformly together the law holds good; but as the state of incandescence is increased a point is reached, varying with each kind of lamp, when the resistance ceases to diminish at the same rate, and eventually to increase. When this occurs the law is departed from, and the light emitted increases much faster than the sixth power of the current. The filament speedily breaks. The point of departure from the law indicates a point when a change of state occurs in the carbon filament. Disintegration probably sets in. This point ought to be determined for each kind of lamp, and it should never be allowed to be reached, for it is from this point that decay commences and rupture follows.

THE DISTRIBUTION OF ELECTRICITY.[1]

When first I was asked to give this course of lectures on "The Distribution of Electricity," I thought it would be an interesting thing, just in a general and somewhat popular manner, to give a description of the different schemes which have been proposed for lighting large installations and central station lighting, and to simply treat what had already been written in a general sort of manner. But as soon as I began to go into the question at all I felt it would be losing an opportunity for doing something which would really be far more useful, and that was to take up the subject from a more technical point of view than that which I had originally thought of, and to discuss somewhat fully these different systems, and explain the defects of each and what were the relative merits of them, and really to go into the question in a more thorough manner than anyone has found it worth his while up to the present time to attack these problems in.

ELECTRIC LIGHTING CIRCUITS.

This then is the scheme which I have had before me in the course of these lectures. You all know the different systems which have been proposed for lighting. You know how arc lights have been distributed in series, and how incandescent lamps have been put on multiple arc in large stations. More especially you are acquainted with what has been done in America in this matter. In some cases only a special system has been thoroughly worked out, and in very few cases, I fancy, have different systems been relatively compared and pursued so as to bring out the most economical condition possible.

Besides these different systems I have spoken of—the series and multiple arc systems—you are aware that the latter, the multiple arc, is subdivided into a number of different ways of distributing. You have all heard people talking about the network system, the system with three mains, and also of lines of centres distribution. There are different modes of multiple arc system. And so also we have another one, which is called the multiple series system, which has been used to a certain extent, and very successfully used, but which has very radical defects in it, which have prevented its general adoption; at the same time, many distinguished engineers believe that in the future there may be a possibility of making this system efficacious and of removing the defects which are in the way. The objection to the ordinary multiple system, where all the lamps are connected to two massive mains, or to a number of wires which are so connected together as to make two massive mains, is the enormous cost of the conductors.

Besides the difficulty that the electric lighting act is simply unworkable, as every unprejudiced person must admit that it is, there is no doubt another fact which has largely hindered electric lighting, and that is the enormous cost of the mains. And not only that, but the multiple arc system introduces another serious expense. It becomes essential with such large mains to have our central station and our engines in the centre of the district which is being supplied. Now, in a thickly-populated neighborhood, such as it would be economical to light on the multiple arc system, it is very difficult to get a site for your engine and dynamos, and this has been acknowledged by those who have tried to undertake the system in London, to be one of the most serious objections to the multiple arc system. Thus at every point we see that it is of the utmost importance that engineers should devote their attention to economy in the construction of their mains to enable us to have a good supply after the most economical system of mains which is possible, whether that system be multiple arc or multiple series, or any other of the modifications which have been proposed.

1. Cantor Lecture delivered by Prof. George Forbes at the Society of Arts, February 2d, 1885.

The question of the production of electricity is one about which I need say very few words indeed. At the present time we produce our electricity by means of dynamo machines, by far the cheapest we have, and there is no immediate prospect of any other system being introduced which is more economical. Secondary batteries, being supplied with their power from dynamos, may be looked upon more as a system of supply than as a means of production of electricity; and the same may be said of secondary generators, which have attracted considerable attention in the last year or two.

COMPARISON OF GAS AND ELECTRICAL DISTRIBUTION.

Before proceeding directly to the problem of the supply and distribution of electricity, let us take a general survey and a comparison between electricity and gas in this respect. The production of gas is a far more complicated operation than the production of electricity; it is a somewhat complicated chemical laboratory experiment produced on a large manufacturing industrial scale. When we come to the supply of gas the problems resemble each other at first sight a good deal. The gas must be supplied in the pipes at a certain pressure, the size of the pipes must be regulated by the supply, the pressure must be maintained, the quantity flowing must be so regulated that it shall not vary to any great amount. In all these points we have an analogue in the case of electricity. I shall use the term "pressure" in these lectures because it is now introduced as a parliamentary term, and I do not see that it is not a correct scientific term to indicate the pressure at any point by indicating the difference of potential between the conductors at that point. We have to do the same thing with electricity as with gas; we must supply it in such a way that the pressure of electricity at different points shall not vary much. There are two points in which gas differs very materially from electricity. The one is that if you take a hundred wires of certain diameter and pass a current of electricity through them, and then pass a current through the same mass of copper grouped in one wire, the resistance offered in the two conductors is the same. If, however, in the case of gas, you pass the gas through a hundred small pipes and then through one large pipe of the same area, you have far more resistance in the hundred pipes than you have in the one. This is the reason why although we often see electrical cables made up in strands, in gas we see them in large pipes as required for the regular flow of gas. The other point of difference is in the cost of mains. The difference consists in this that with gas the pipes are hollow and it is simply the space which is filled with the illuminating material, gas, while in electricity the conductor is solid and the electricity passes through the solid material. The consequence of this is that whereas in gas the cost of mains is not in proportion to the quantity of gas which is to flow through those mains, in electricity it is certainly fully in proportion to the quantity, and that is why when we come to large electric mains we have such an expensive system to deal with.

While I am comparing with gas, allow me to say just one word about the introduction of electricity. It astonishes one to think for a moment how serious have been the difficulties in introducing electricity when really the obstacles to introducing gas were so much greater. When gas was introduced people knew nothing about a central supply of an illuminating agent, and knew nothing of the requisite size of pipes. It was a leap in the dark. The gases were objectionable, the burners infamous, smoke and sulphurous fumes were given off, and from the naked flame there was a constant danger of setting fire to houses; the gas vitiating the air, blackening surrounding objects, and the smell objectionable. Moreover it was impossible to prevent leaks, and leaks meant explosions. It was impossible to prevent ignorant people from blowing out gas or leaving cocks turned on, and in that way explosions and deaths from suffocation resulted. Electricity has none of

Digitized by Google

these disadvantages. There has been great talk about risk from fire and risk from shocks. There is nothing of this, a properly laid line gives infinitely less danger, even with a high potential than that from explosions and fires by gas.

THE GENERAL PROBLEM OF ELECTRICAL DISTRIBUTION.

Now then let it be taken for granted that what the engineer has to do is to reduce the cost of his mains as greatly as it is possible. Our object then is to diminish this cost, and whenever we find that by diminishing the cost of our mains we are introducing a new engineering difficulty, then that is a problem for the engineer to overcome, and he must overcome it some way or other, if it possibly can be overcome, rather than increase the cost of his mains. Now there are three different reasons why it is objectionable to diminish the size of the mains too much: First, the great wasting in the energy which is used up by the resistance of those mains. We have to supply so much extra power in our central station in order to waste much simply by the heating of those mains, and that means an annual expenditure of a certain sum of money, whereas if we had made the mains a little thicker, we should not be wasting so much energy, and therefore in the primary outlay of a certain sum of money we should be saving an annual expenditure. The question is, of course, to balance these two matters in such a way that we arrive at the most economical result.

Now let us just look at the problem with a few figures before us to see on what scale we are dealing. Suppose that we are using a conductor of a square inch section to carry 1,000 ampères. The resistance of 100 yards of that conductor of pure copper would be ·0024 of an ohm. Now the energy which is used up is given you by the calculation $C^2 R$ divided by 746. That is equal to 3·2 h. p. used up in every hundred yards of our conductor for every thousand ampères. Now what is the cost of this electrical h. p. per annum? It is usually considered safe to say a h. p. costs £10 per annum, but owing to the period in which electricity would be used that is not a safe figure. Let me begin by considering £20 as the cost of h. p. £64 is the cost of the total h. p. We have wasted in four years in every hundred yards £256; in 20 years £1,280 is wasted in that conductor. Now, if I double the size of my conductor, I have the quantity of power wasting reduced to £640. The question comes to me, would it cost more than £640 of capital to lay down an extra hundred yards of a similar section? No, it would not, and therefore it is economical to double my conductor. And so we go on, step by step, until we find that the gain is just equal to the extra expenditure of capital in the laying down of conductors, and then we have

arrived at a satisfactory arrangement. You will easily see if you work this out. Now this is an important point, in fact one of primary importance. It was first approached by Sir William Thomson in an address to the British Association in 1881, in which he read a paper on "The Economy of Metal Conductors of Electricity," and in a most interesting paper he arrived at the conclusion that the interest on the capital spent upon the conductors should be equal to the value of the energy which is wasted annually in these conductors.

COST OF AN ELECTRICAL HORSE POWER.

The first question which becomes a trouble is, what are we to consider the cost of electrical h. p.? There are two ways of looking at this problem, and we will just glance at them independently. First, let us take the case of an installation which has been thoroughly carefully estimated for, and let us see there, after the whole of the buildings, distributing and supply plant, and everything has been laid down, what is the cost of each h. p. of electricity, if you like to call it so. To give you a perfectly unbiased example, I have taken the figures, kindly furnished by Mr. Crompton, of a large installation which he carefully prepared estimates for. I find, on looking into this, that in this case the cost of electrical h. p.—of course, depending on the number of hours used during the year—if it was for 1,000 hours, the cost of h. p. came to about 5d.; for 2,000 hours in the year, 3·5d.; and for 3,000 hours only 3d.; and that means, for the year in these three cases it would be 5,000 pence, 7,000 pence, and 9,000 pence. Now the next question that comes before us is, what is the number of hours we are supposed to use our electricity? There is very little doubt that about 1,000 hours is probably a fair average consumption of people in a town; but I think it very likely that, at any rate, in the first installation set up a certain selection will be possible, which will raise the average a little higher. For my own purposes at present, I am going to assume 1,500 hours; if you prefer another value you can work it out yourself to suit it. That will be the average cost of those two, which comes almost exactly to £25 a year. Now if you work out the cost of the energy wasted in a 1,000 yards conductor, you will find, I think, that the following figures are energy wasted in the conductor for 3½ inches, 4 inches, 4½ inches, 5 inches, 5½ inches, 6 inches, and 6½ inches; the amount is £22·8, £20, £17·8, £16, £14·5, £13·2, and £12. Therefore, the gain in passing from this to this is 2·8, 2·2, 1·8, 1·5, 1·3, and 1·2. These are the gains which there are in increasing the size of the conductor. Up to this point it is all plain sailing, a matter of plain calculation. The next thing is, what is the interest on the capital which is expended? This, of course, depends on the way in which the mains are laid, and different people have different ideas about how they should be laid. Many people lay mains at present with stranded cables. For my own part, I cannot see what is the object of doing this; it is the most expensive form in which you can produce your copper, and really nothing is to be gained. It seems to me simply to arise from the fact that cables we used previously were submarine cables, and certainly they are of great advantage there; but why they should be used on land, where there is no strain, I see no earthly reason. Others think they should be laid in massive bars of semi-circular shape, covered with bituminous compound; others that in flat sheets laid in troughs. At any rate, every person differs from every other, and consequently every person must have a different value for his cost of copper. But I have taken it as an example, simply, and you need not take the value I use. Take the £100 a ton as the cost of adding an additional amount of copper to our mains, after the troughs and so on have been laid. In that case the interest upon it depends upon the percentage which we allow. Now, what are we to allow? Ought it to be 5, 7½, or 10? That, again, is a question for the engineer to determine for himself. But allow me to

point this out, when we are increasing the size of our mains, really we ought to be diminishing the percentage allowed for maintenance. The wear and tear is less, heating is less, the danger to insulation is less, everything leads us to believe there is a less cost of maintenance with a large conductor than with a small. This is a very important point. Each one must judge for himself whether to take 5, 7½, or 10. He will find with 5 per cent. the annual cost is 1·27, at 7½ per cent. 1·91, at 10 per cent. 2·55; so that what we have to do is to find that size of conductor which should equal the interest which we happen to consider the right interest. Supposing 5 per cent., then we have 1·27 settled, which gives 6 inches; 7½ per cent. 1·91, about 4 or 4½ inches; and 10 per cent. 2·55; between 3·5 and 4 inches for a 1,000 ampères. I have gone through this example carefully, just to give you a clear conception of the way in which the problem is to be worked out, but I think you may very safely say that the consumption I have taken is too large. It is perfectly true that in this estimate to which I have alluded is included the cost of buildings, engines, dynamos, boilers, and other machinery, the mains, and also includes the annual cost of coals at 18s. per ton. Well, all these points to come in, therefore it is a question for each one to consider for himself how far these things are to be divided in this way. It may be said by some, however, that it is desirable only to look upon our plant as being fixed, and supposing we want to carry extra current on the same size of conductor, would it be wise to do so or not?

I may now draw your attention to a table which I have drawn out for these lectures, which I have found of great use already, and which I believe all electrical engineers will find of use, too.

THE ENGINEERING PROBLEM.

The engineer can choose his facts for himself absolutely, can choose what he considers to be the right value of the electrical h. p. every year for the number of hours he proposes to run. He can also choose the cost of copper which he thinks it will suit him to lay. Having done that he proceeds in this manner: I will take as an example copper costing £100 a ton; take 7½ as the rate of interest; I look along the column of table II*b*. until I find £100, look down until I come to 7½ and find the figure ·386. I then look to the top of the table II*a*. and I have £8 a year, say, for my electrical h. p. I look along the column of £8 a year until I find the figure nearest to ·386 and I find that it comes to a place beneath the number 2·7; in that case 2·7 would be the square inches which are required for the main on those conditions imposed by the engineer himself. I have given another table for continual reference, giving the resistance of 100 yards and various other facts, also the current which will heat the wire.

Before leaving the subject of the cost allow me to once more impress upon you that I consider this matter of primary importance and no considerations must ever lead the engineer to deviate from the strict rules which regulate the cost. It may be in some special cases not always practicable to regulate our wires to carry the current exactly at this rate. It may be because it is easy to get a stock of conductor of a slightly different size, or it may be inconvenient to be always varying the estimate in the size. But these principles must be gone into for every part of the scheme, and in our practical application we must stick as closely to our results arrived at there as we possibly can. It is no use for the engineer to say financial people will not bring forward the money for these costly mains. The engineer, in my way of looking at it, has no right to look at what the financier wants to do. He must tell them honestly what is the most economical thing to do. If the financier wants to lay out capital in a particular direction knowing that he will be causing a waste of energy, the engineer ought to have nothing to do with such matters. He ought honestly to give the value of the current which is most economical.

I have dealt now fully enough with the first cost that prevents us from diminishing the thickness of our conductors. The second cause why we should not reduce too much is the heating of the conductors. There are in this three injurious facts—in the first place it spoils the insulation; the insulating power of the material diminishes by being heated, and the material itself becomes injured; moreover, when it is hot it usually becomes soft and the conductors can sink into it and so become decentralized. And in the second place the conductors themselves are injured, because their resistance is increased by the increase of temperature, and these increases of temperature, mark you, are very considerable. And in the third place the increase of temperature may be very serious, and may actually be objectionable along the streets. I have here a small piece of cable which shows the decentralizing action of bituminous compound. This has been lying for six or eight months in a cool part of a cool room, always lying in the same position. I believe when I got it it was perfect, but in a cool place it gradually sunk, and now it is very decidedly out of centre. An old experiment which I used to show when I held my chair at Glasgow illustrates the viscosity of objects. It was first suggested to me and I first saw it done by Sir William Thomson in his laboratory. By taking hard, brittle pitch—or shoemaker's wax would serve the same purpose—take a block of it, put a bullet on the top and corks underneath; in six months the bullet will have sunk into the block and the corks will have risen several inches up through it. This simply shows you how such bituminous compounds must be carefully watched, and how very objectionable is any viscous material in the way of decentralizing the conductor.

DEVELOPMENT OF HEAT IN CONDUCTORS.

Now as to the question of heating conductors, I will not take up much of your time this evening, because I have already in a lecture which I gave at the Society of Telegraph Engineers last year, gone into the question very fully.

I only draw your attention to the question now because there is an important point which I am glad to say needs correction. A discovery has been made of an error near the end of the paper which might be misleading, and which probably has misled some. I will give you a corrected edition of it.

Here is the table to which I have referred. It gives you underground conductors. I have recommended sheets of copper for underground conductors, because the temperature is far less raised when you have a thin conductor.

Width in inches of copper conductor 1 cmr. thick.	Cross section in square inches.	Current to raise surface temperature 10° C. ampères.
3·2	0·25	250
12·7	0·98	1,000
38·1	2·95	3,000
63·5	4·92	5,000
127·0	9·84	10,000
889·1	68·88	70,000

This is a most important point. We have absolute control over the temperature; by widening out our sheet we have diminished temperature, and can make the heat of conductors subservient to economy.

I pointed out that if you do not bury your conductors more than about two feet the surface temperature is not affected; only the temperature of the conductor. If you go two feet deeper you will affect the surface temperature also. I have thought that up to 10° centigrade is the limit endurable by foot passengers. In the summer the rising temperature of the pavement is most objectionable; fortunately this is the time when the current is least used. Moreover the temperature does not immediately pass through the ground. The daily variations of surface temperature differs as the diurnal change of position of the sun: it does not penetrate very deep down—is very slightly perceptible at two feet depth. And if we have 500 ampères flowing for 24 hours, the effect would be almost exactly the same as if 1,000 ampères were flowing for six hours. Another point, if instead of laying a sheet one centimetre thick, you might lay cables with the same result provided the average thickness was one centimetre.

PROPER SIZE OF CONDUCTORS.

In speaking of the economical size of conductors, I arrived at the conclusion that I must use 2·7 inches, or say 3 inches for 1,000 ampères; but mark you, though 1,000 amperes is the average current, it is not the maximum current to pass through that conductor. The maximum is a very different thing indeed to that. When we have an average of 1,000 ampères it does not in the least mean that that is the average quantity of current which is flowing through it, because the wasted energy depends upon the square of the current. This leads to a very different law, and a very important one, about which I have a word or two to say. Suppose n_1 is the number of hours during which a quarter of the lamps are burning, n_2 one-half, n_3 three-quarters, and n_4 the number of hours during which all the lamps are burning.

Then the average quantity can be got from the maximum quantity by multiplying all these fractions. If half the lamps are burning two-thirds of the time and the rest of the time all the lamps are burning, we get a equal to ·5. Therefore, instead of having 2·7 we only have 1·35 as the sectional area for 1,000 ampères. As a matter of fact I shall select for the rest of the lectures the quantity 1·5 square inches to the maximum current of 1,000 ampères. It seems to me for a working hypothesis, which no one need adopt, a good enough value.

The third reason why we cannot reduce the size of the conductors too much is that the potential falls, and the thinner the conductor the greater the fall of potential between the dynamo and the lamps. With a large current there is a great fall of potential (experiment shown), thus showing that in a central lighting station the fall of pressure, and therefore the brightening of the lamps in the district, depends upon the number of lamps in use at the time.

Ratio of $\frac{\textit{average}}{\textit{maximum}}$ *current.*

n_1	n_2	n_3	n_4	a
0	0	0	1	1·000
0	1	0	1	0·790
1	2	2	1	0·744
1	1	1	1	0·685
2	2	1	1	0·604
0	2	0	1	0·500

This is a serious thing, and the most difficult engineering problem with which we have to deal. We have arrived at the consideration that a square inch and a half for 1,000 ampères is the size we must use, that means a fall of potential of 1·6 volts for each conductor in every 100 yards, that is to say, a fall of nearly 3¼ volts with the double conductor for a distance of 100 yards, and whether you like it or not you must have it. It may be met by making distant consumers use lamps requiring a different pressure to those nearer. This is the thing which has given most trouble, and the point will be considered in the next lectures.

SYSTEMS OF LAYING CONDUCTORS.

I had hoped to have gone a little into a description of systems of laying mains which have been already adopted, but time is pressing too much. I will just say a few words about some of the systems I saw at the Philadelphia exhibition last year. People seemed to have missed altogether the point that is to be aimed at in underground conductors. There was a list of inventions shown, simply consisting of tiles with holes through them, the cables to go through the holes. For low potential work it is not such a very difficult thing, and there has been a fair trial.

EDISON'S CONDUCTORS.

Outside in inches.	Area of one conductor in circular mils.	Maximum current in ampères.
3·5	1,639,890	1,400
3·0	862,976	760
2·25	262,951	370
1·31	107,289	220
1·05	33,000	100

These are laid in bituminous compounds in iron pipes, and seem to work pretty well for low potential work, but every electrical engineer thinks we shall be able to introduce high potentials some time or other, and reduce the cost of these mains.

DIFFICULTY OF INSULATION.

What is it that makes it so difficult to insulate these mains properly? It is very difficult to say. It may be that there is a faint leak, and a spark passes to the iron pipe in which the conductors are encased and that gives rise to an increasing leak. It may be that where there is the faintest leakage there is a partial decomposition of the water that comes into contact with it and that brings electrolytic action into contact with the insulating material, which we know it generally destroys and so the leak becomes worse and very bad indeed. Through the kindness of the Brush company I have here a specimen of a fault in one of their underground city conductors showing where it is eaten into. In Philadelphia there were some systems shown in which there was a very wide trough and glass

Digitized by Google

plates introduced here and there, in which was a large number of holes. Glass is a very bad substance to use; it gets such a moisture upon it that I should not have thought it was the best thing to use, and beside there is a tremendous wasting of space for small wire. In another, copper rods were carried through pipes made as water-tight as possible, supported on rings of glazed porcelain so that there is a very small surface of leakage possible. With the rings here and there of course dampness was a serious obstacle; and in this system it was proposed to blow dry air through the pipes so as to keep the moisture continually out of them. I can only say of this that it is only a proposition, the thing has never been done.

UNDERGROUND CONDUCTORS.

I had hoped to speak to you of what has been done in underground conductors, but really there is very little to tell you and that can be said in very few words. In Philadelphia there was a system of underground conductors put down by the Excelsior company, and they worked pretty well. They used large troughs and where there are large troughs there is no difficulty about it. But these large troughs had very serious inconveniences that one hardly expected from electricity. Three times during the time I was at Philadelphia the troughs in Chestnut street blew up, a most unexpected result from an electric conductor, but it was a positive fact, and the secret was they were too near the gas mains, which leaked and positively filled the troughs and consequently they blew up. However, these were accidents that might have been prevented with care.

I have an illustration here of the installation at Colchester, which illustrates the way in which very large troughs are laid with conductors cut along them.

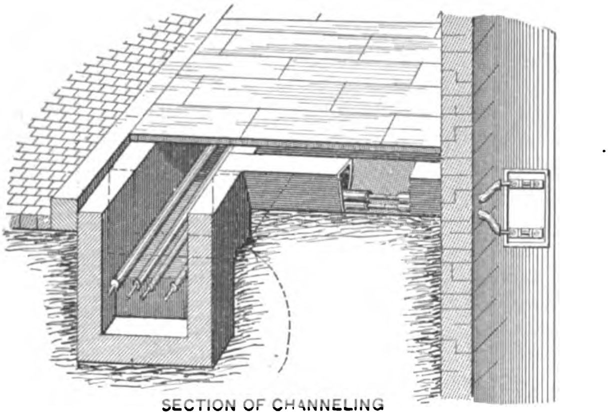

FIGURE 1.—CHANNELLING SHOWING CHARGING AND SUPPLY CABLES.

The Jablochkoff company on the Thames Embankment has had a lengthened experience extending since 1878, with a small $\frac{7}{16}$ strand wire covered with gutta-percha and tape and put in troughs underground, where it has given very little trouble. Then, again, in the city the Brush company has had these conductors underground since April, 1880, and they have had a great deal of trouble. They tell me that they were put in first very loosely and covered with sand for some reason or other, and in drawing the cables through the pipes the sand wore them away and the consequence was the insulation went.

Here is a curve showing the insulation resistance of these cables extending over a lengthened period. The variations of the curve indicate continual cases of faults being discovered. This is a very instructive curve, and shows the difficulties of working with conductors simply laid in the ground in that way. I have no doubt that other people have had large experience with high potential conductors, and I wish I could have succeeded in getting a larger number of facts to put before you, but unfortunately I have not come across them. This lecture is simply preparing the way for the consideration of different systems of laying conductors. In succeeding lectures we

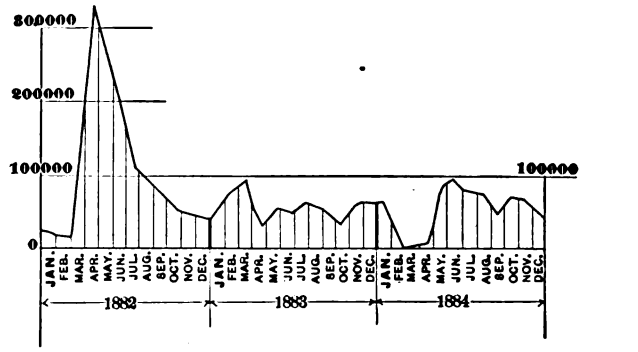

FIGURE 2.—INSULATION RESISTANCE OF UNDERGROUND CABLES.

shall see how engineers have attempted to get over the problem of fall of potential, and how to combine economy with efficient working.

ATMOSPHERIC ELECTRICITY.[1]

BY LUCIEN I. BLAKE, PH. D.

SINCE the earliest times, the electrical phenomena of the atmosphere have been a cause of wonder and fear. The manifestations, on the one hand, of prodigious power in the lightning and thunder, or on the other, of a subtle force, in the mysterious manner life is destroyed, or objects instantly rent into pieces, have naturally led thoughtful minds, in all ages, to seek an origin for this atmospheric electricity However, up to the time of Volta in 1782, no theories had taken definite expression. The gods of the Greeks and Romans rumbling around in the air above, or probing now and then the ribs of mother earth with fire bolts, did not long satisfy common sense.

Volta found by experiment, with what now would be a crude electroscope, that an evaporating liquid produced electricity. He therefore saw in the immense evaporation from the ocean going on in the tropics a sufficient cause to continually stock with electricity the vapor currents pouring off toward the poles. Upon condensation of these vapors then, as they strike cooler currents, their electricity became apparent in lightning, etc. The moisture itself as *vapor* was a non-conductor, and consequently each vapor particle contained merely the amount of electricity first given it at evaporation. On condensation, however, the electricity would spread to the surfaces of the conducting cloud masses, and with sufficient increase of electrical density manifest itself in lightning and thunder phenomena. This theory seemed so plausible that, being corroborated by Volta's experiments, it was quite generally accepted. Forty-five years afterward, in 1827, Pouillet,[3] with better apparatus, repeated Volta's experiments and obtained similar results—that evaporation did produce electricity. Further, in our own day, Tait and Wanklyn[4] likewise assert a production of electricity in their experiments on evaporation.

However, there were other experimenters of authority who asserted exactly the opposite,—that *no* electricity was produced by evaporation. Saussure,[5] in his "Voyages dans des Alpes," 1786; Erman[6] in Germany in 1818; Gaugain[7]

in France in 1854, and Riess[8] in Germany in 1853, each with better apparatus than either Volta or Pouillet had, failed to detect a production of electricity by simple evaporation. Riess, moreover, showed that in Volta's and Pouillet's experiments, the electricity obtained was due to *friction*—especially when the liquid was in the spheroidal state, as in most of their experiments. The results of Riess are now generally accepted, and *evaporation from the ocean's surface* discarded as a sufficient cause of the great quantities of electricity in our atmosphere.

A *second* hypothesis has been widely accepted in both former and our own times. Benjamin Franklin[9] was among the first to propose it. Becquerel[10] and De la Rive[11] in France, advocated it, and it is adhered to by some of the greatest modern scientists. The surface of the ocean is known by experiment to be electrified. The vapors arising from it, especially in the tropics, carry with them its electricity into the atmosphere, and then in their condensation the electricity again becomes apparent. This theory is so simple, and since it has been always stated *as a law*, and never questioned, that vapor arising from an electrified surface carries the electricity away with it, the theory is being more and more widely adopted as an explanation of the cause of atmospheric electricity. Sir William Thomson has been also numbered among its adherents. The whole theory evidently rests upon the law mentioned above, and which is stated in the text-books as the law of the convection of electricity by vapor from an electrified surface. This so-called law I shall show, from a course of experiments which I had the opportunity of carrying out a year ago, is false. *No* electricity is conveyed by vapor arising from a surface, however strongly electrified that surface may be. The experiments, the results of which were brought by Helmholtz before the Royal Academy, were conducted in brief as follows :—

In the *first series* of experiments, two brass discs, about five inches in diameter, were brought, so that their faces were separated about $\frac{1}{25}$ inch (1 mm.) from each other. These discs were very carefully insulated, and one of them was connected with one pole of a zinc-water-copper battery of 500 elements. The other pole of the battery was to ground. The disc became thus statically electrified to about 400 Daniells. On the electrified disc a layer of water was placed by condensation, and then the disc was gently warmed on the backside by a flame. The flame was then removed, for a flame always produces disturbing electrical effects. The other insulated colder disc was now brought up opposite it (1 mm.) as mentioned above, and the vapor of course, passed across from the moist warmer electrified disc and condensed upon the colder unelectrified disc. This latter disc was connected with a Helmholtz quadrant electrometer which was so sensitive that one Daniell cell gave a deflection of its needle of 70 mm. scale divisions, when the scale was about 15 ft. from the mirror of the needle. This electrometer differs from the Thomson quadrant electrometer principally in charging the *quadrants* permanently, and putting the electricity to be tested upon the needle, exactly the reverse of Thomson. Under the above conditions of experiment, the electrometer gave not the slightest indication of electricity upon the colder disc, notwithstanding the vapor which had just left the highly electrified surface condensed in heavy drops upon it. The electrometer was capable, as stated, of indicating $\frac{1}{140}$ of a Daniell, and here the electrified disc, from which the vapor came, had a potential of 56,000 times that amount, and not a trace of electricity was revealed as coming with the vapor.

The second series of experiments was to allow evaporation from *different* liquids. Among these were salt solutions, alcohol, sulphuric acid, and *ocean water*. They were put, in turn, into a shallow porcelain dish which was insulated, and connected with one pole of the battery mentioned above, whose other pole was to ground. Then this liquid was gently heated, until rapid evaporation took place, and the flame was removed. Over the liquid was suspended a cold brass disc, which was insulated and connected with the electrometer. The vapors now condensed in large drops on the disc, but the electrometer indicated not a trace of electricity, coming with them. To make the potential of the liquid still higher, I electrified it by a Töpler-Holtz machine, which I ran with great regularity by a little water-motor. Sparks would now pass from the surface of the liquid to the disc suspended over it. Then the disc was moved just far enough from the surface of the liquid so that the sparks could no longer pass—*i. e.*, just the slightest degree farther than the so called "striking distance," and of course then the electrification of the liquid was at its maximum. But even under these severe conditions not a trace of electricity went over with the vapor, which one could see rapidly condensing.

Finally, to make it still more general, mercury was used for the liquid. [The apparatus had to be somewhat altered of course.] According to the latest chemical theories a molecule of mercury contains only one atom of mercury, unlike all other gases which contain at least two. In the evaporation of mercury then we would have *atoms* arising from the electrified surface of the mercury and passing to condense into drops upon a platinum disc opposite. But here as in the preceding not a trace of electricity manifested itself upon the unelectrified disc. From such experiments there is but one conclusion, that the universally accepted law of the convection of electricity by vapors from an electrified surface is untrue. Any *theory* then, which would explain by it the cause of our atmospheric electricity must of course be given up. The question remains *still unsolved*, whence comes the great quantity of electricity constantly present in our atmosphere, and yet a first step to its solution is taken when we clear away existing theories which are defective, and thereby reopen the field for new researches.

The French Academy, to stimulate investigation in this line, offers a prize of 5,000 francs for the correct solution, before Jan. 1887. But to anyone there should be a greater incentive in the meteorological value of an accurate knowledge of the source or sources, and laws of action of atmospheric electricity.

Experiments already show that the electrical disturbances in the air are closely connected with and generally precede changes of weather.

Our government learning of this, has this last winter established two stations respectively at Harvard College and Johns Hopkins University in Baltimore, where electrical indications of the atmosphere are automatically registered. A change from positive to negative electrification generally precedes stormy weather, and so marked an indication, if proven as a general law, *may* become an important factor to our signal service bureau. At least when observations are taken simultaneously over large areas, laws *may* be discovered, which, combining with present meteorological methods will enable weather to be foretold with much increased accuracy and corresponding value to our commercial interests. This fact it is which should lend an impulse to research into the phenomena and cause or causes of our atmospheric electricity, and which, I think, justifies me in not considering this branch of experiment foreign to the aims of our Electrical Society of New York.

After the reading of the above, the President, Dr. Van der Weyde, made the following remarks:

Admitting that the existing theories upon the origin of atmospheric electricity are not fully satisfactory to explain all the details of the phenomena exhibited, we must, in order to be just, present these theories fairly and fully and not incompletely. In the paper just read, only one part has been stated, and the most important part omitted, as will be clear when I have explained the whole of the theory. Peltier a French physicist some forty years ago

demonstrated that not only the surface of the ocean, as stated in the paper, but also the land, in fact the whole terrestrial surface possessed normally a charge of negative electricity, and that this charge is stronger in elevated portions than in valleys, according to the well-known law of static electricity which in a charged sphere will accumulate on the projecting parts. If a cloud comes in contact with the earth and forms what we call mist, it will become charged, and this charge will for the same reason accumulate on its upper surface, the electricity ascending as far as the conductivity of the cloud extends, while on the earth's surface no electricity will be perceptible; conformably to the law, that beneath the surface of an electrified body no electric charge will be perceptible; this fact is often illustrated by a variety of lecture-room experiments.

If now such a cloud or mist ascends, and becomes separated from the earth by a layer of non-conductive air, it will carry its negative charge to the upper regions, and this is one of the ways in which the atmosphere may become electrified. There is, however, another much more important and active operation going on, which is decidedly the most prolific source of atmospheric electricity; viz., static induction by an electrified terrestrial surface upon conducting clouds separated from it by a layer of non-conducting air; this great factor in the development of atmospheric electricity is entirely overlooked in the paper.

The law of static induction is well established and demonstrated by experiment. It is as follows: Any electrified body exerts upon a conductor within the sphere of its influence a peculiar action; this consists in disturbing the neutral condition, and causing a separation of the two inherent and mutually neutralizing electricities, in such a way that the electricity of the same kind as that in the electrified body will be repelled, and that of the opposite kind attracted, resulting in an electrified condition of the neutral body, which will manifest opposite electricities at its two extremities. In fact it is an extension of the law that opposite electricities attract one another, while those of the same name exert a mutual repulsive action. If we now apply this to the earth and the clouds, it is evident that a negatively charged terrestrial surface must make the under surface of the clouds positively electric, and their upper surface negative. Such a cloud layer may act upon other higher layers, and induce other charges, in fact we may have the experiment of the so-called cascade of Leyden jars or condensers on a gigantic scale; winds may now separate the positively charged portions from those charged negatively, and we obtain a variety of electrified clouds, which will exert their attractive and repulsive actions among themselves, and even also exert in their turn inductive action upon the earth, so that negatively charged clouds may induce that part of the earth over which they float to become positive. If we look at all this, we need not wonder at the immense amount of electricity manifested during thunder-storms, especially when we consider that an electrophorus will permit us to draw an unlimited number of sparks from its plate, and all this by inductive action—without losing its own charge. In a certain sense the earth acts like a gigantic electrophorus.

This theory, with which by a peculiar circumstance I became acquainted a short time after its first conception by the younger Peltier, I have always considered entirely adequate to explain the phenomena of atmospheric electricity, and it has commenced to be so considered by all authors of text-books who write them otherwise than by compiling older ones. The problem may at present be considered as reduced to these questions: How does our earth obtain its negative charge? Is it naturally provided with a charge which cannot escape across the interplanetary space? (We have now strong reasons to suppose this space to be an absolute non-conductor of electricity.) Is the electric charge continually developed by active volcanoes, vegetation or evaporation? The latter is very likely, and the experiments mentioned in the paper read, were originally intended by Pouillet, Matteucci, Helmholtz, and others, not to prove whether watery vapors conduct electricity, but whether evaporation will develop electricity in such a way that the ascending vapors will be positive, and leave the insulated receptacle from which the water is evaporated negative. Watery vapor may or may not conduct electricity, according to the dew-point; and this depends on three factors: temperature, amount and tension of vapor, and atmospheric pressure. When heated above the dew-point, watery vapor is a non-conductor, when below, it is a good conductor; witness the clouds, which are excellent conductors. This is the reason of the discrepancies in the results obtained by different experimenters, some of whom when they wished to test the development of electricity by evaporation, lost the electricity developed by conductivity through the vapor itself, or when they wished to demonstrate that vapor will conduct electricity, evolved a vapor at a temperature above the dew-point. If by artificial heat we wish to develop vapor which will conduct electricity, the temperature should not be too high; the air of the room should be moist, and the barometer low; if on the contrary we wish to obtain vapor which will not conduct electricity, we must make our experiment in a dry season and locality, with sufficiently high temperature and barometer. Such were the circumstances by which Pouillet and Matteucci obtained decided indications of the development of electricity by simple evaporation, Pouillet from salt water, and Matteucci from moist earth; to this we may add Volta, Laplace and Lavoisier who found that when water was dropped into a hot platinum crucible, electricity was evolved. Against positive results thus obtained, the failure of others who did not succeed amount to nothing, as negative proofs are no proofs whatsoever. Any person having had some experience in physical research, especially with electricity, knows how diversified may be the causes of failures in obtaining the results expected, and how often experiments fail, except when we are able to detect the causes of failure, and to have them corrected at once. One single successful experiment of this nature is a more convincing proof than a hundred failures.

TESTS OF WOODHOUSE & RAWSON'S INCANDESCENT LAMPS.

We give below a summary of the results of tests of these lamps made by the jurors at the Vienna exhibition. It will be seen that they show a very high percentage of efficiency even when run much below their normal candle power. The lower line gives the average efficiency of the whole number of lamps tested, namely 2.38 watts per c. p., or 312 candles per h. p.:

Normal C. P.	Observed C. P.	Current in ampères.	Difference of Potential in volts.	Resistance hot in ohms.	Watts.	Watts per C. P.	No. of candle per electric H. P.
20	4.64	0.779	35.24	45.26	27.44	5.91	122
	6.85	0.838	37.65	44.95	31.54	4.60	160

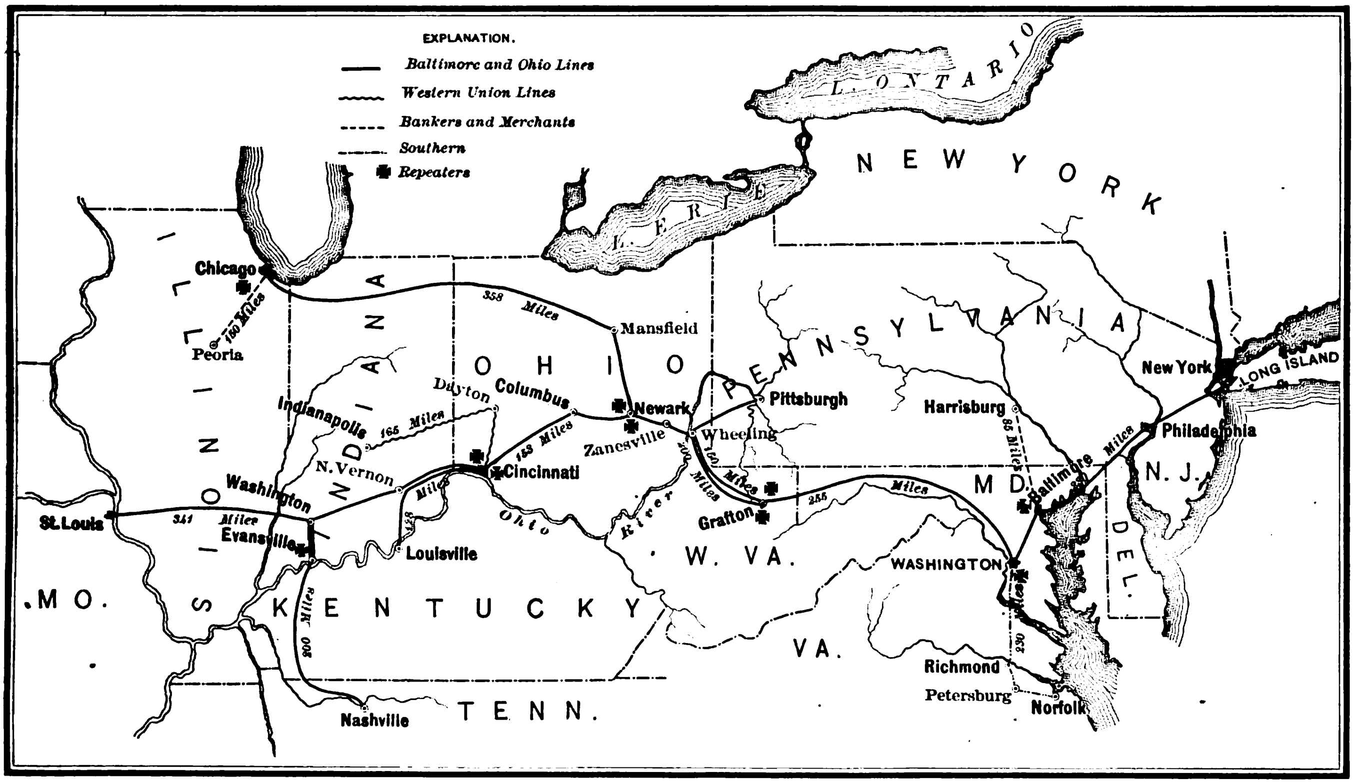
AN EXTENSIVE MORSE CIRCUIT.

UNDER the management of Mr. Walter P. Phillips, the United Press has built up an enviable reputation for its news service. This is largely due to the practical telegraphic experience of that gentleman, who has done more than any one person to facilitate the delivery of newspaper copy in the most satisfactory manner possible, by placing instruments and operators in the editorial rooms of such journals as desire to make arrangements of that character. In carrying out his ideas, he has found it necessary to transmit "direct" to every possible point, and a glance at the map given herewith, will show how well he has succeeded. The fact that at most repeating offices, an operator is required to serve a client at that point, has enabled Mr. Phillips to avail himself of that old and reliable device, familiarly known as the "button repeater." It has been somewhat improved; the repeating in both directions being effected by a single contact spring, which being almost continually in use, is properly cared for, and always bright. The automatic repeaters generally used if not constantly watched are liable to get out of adjustment, causing trouble all along the lines. As the service requires operators of the highest skill at all points, this apparently complicated circuit is managed without difficulty. The wires are leased by the United Press from the Western Union, Baltimore and Ohio, Bankers and Merchants' and Southern Telegraph companies, and operated direct from their office, 187 Broadway, New York. There is apparently no limit to the extension of this system to any point in the United States where a demand exists for the service of the United Press. The present mileage operated in one working circuit every night is 2,635 miles, as follows:

	MILES.
New York to Washington, via Philadelphia and Baltimore	230
Baltimore to Harrisburg	85
Washington to Norfolk, Va	220
Washington to Grafton, W. Va	255
Grafton to Pittsburg	150
Grafton to Newark, O	200
Newark to Chicago	358
Newark to Cincinnati	153
Cincinnati to Louisville	123
Cincinnati to St. Louis	341
Cincinnati to Dayton and Indianapolis	165
Chicago to Peoria	150
Washington, Ind., to Nashville, Tenn	200
Total mileage	2,635



WESTERN NIGHT CIRCUIT OF THE UNITED PRESS. Total length, 2,635 miles.

ELECTRIC MOTORS ON THE ELEVATED ROADS.—CORRECTED FIGURES.

BY CHARLES G. CURTIS.

IN calculating the h. p. of the locomotives on the elevated railroads, for comparison with the operating cost of obtaining the same power by electricity, as given in the March ELECTRICIAN AND ELECTRICAL ENGINEER, I omitted to add that *part* of their power which is expended in starting the train or overcoming its inertia; not supposing that this would amount to any considerable portion of the whole power. Upon calculating this item, however, it turns out that, where the stops are as frequent as three to the mile, the power required for this purpose is a large portion of the whole; and the actual power of these locomotives has been greatly underestimated—so much so, that instead of burning 15-20 lbs. of coal per h. p. hour, as supposed, they burn only between five and ten lbs.

On the Third avenue road for example, the stops are about one-third of a mile or 1,700 feet apart. Consequently for every 1,700 feet traveled by the train, its inertia has to be overcome, or in other words an amount of *living force* corresponding to its *maximum velocity* attained must be stored up in the train. The work of doing this or the energy in foot-pounds stored up in the moving train is equal to $\frac{W v^2}{2 g}$; W being the weight of the train in pounds, v its velocity in feet per *second*, and $g = 32.2$ being the *acceleration of gravity*. Assuming the weight to be 170,000 lbs., and the maximum speed reached to be about 23 miles an hour, or 33.3 feet per second, the energy would then become $\frac{170,000}{64.4} \times 1,100 = 2,890,000$ foot-pounds. That is, 2,890,000 foot-pounds has to be ex-

pended between consecutive stations in bringing the train to maximum speed, and none or very little of this energy is recovered because, as a matter of fact, the steam is kept on and the speed maintained until it is time to apply the brakes.

In other words, the locomotive must do 2,890,000 foot lbs. of work every 1,700 feet traveled by the train, in addition to that necessary to perform the work of *traction* or simply overcoming the friction. The average speed of the trains being 1,100 feet per minute, the mean foot-pounds per minute expended simply in overcoming the train's inertia would be $\frac{11}{17}$ of 2,890,000 or 1,870,000 = 57 h. p.

In addition to this the power of the locomotive is also occupied in traction or simply overcoming friction for about four-fifths of the distance between stations, steam being shut off the rest of the distance. Taking the weight at 170,000 lbs. a coefficient of traction of .004 and the mean speed at 1,100 feet per minute, the work of traction per minute would be four-fifths of 748,000 foot-pounds = about 600,000 foot-pounds, or about 18 h. p. This, added to the h. p. expended simply in imparting velocity to the train, shows the necessary power of the locomotives to be about 75 h. p. As they burn 500 lbs. of coal per hour at this mean speed, they therefore burn 6.6 lbs. of coal per h. p. hour.

It is a possible thing to get large stationary engines to furnish power at the rate of 2.5 or even 2.25 lbs. of coal per h. p. hour ; but, it is an extreme figure, and probably there are no engines now in operation that are regularly doing as well as this, especially where the power is subject to any variation. Certainly no such result as 1¾ lbs. can be safely counted upon—the figure assumed by Professor Farmer in his estimate published some months ago. But in order to favor the electrical side of the question as much as possible we will assume that the stationary engines will require only 2.5 lbs.

It does not seem safe to assume that the mean counter E. M. F. which it is practical to obtain from the motors will reach much more than 50 per cent., and this would give a net *efficiency of transmission* of about 40 per cent. Here, again, Prof. Farmer has based his estimate upon another very extreme figure,—a net efficiency of about 80 per cent., which seems not only not warranted by fact but apparently impossible under such conditions. If the net efficiency be taken at about 40 per cent., it would require 2.5 times 2.5 lbs. or 6.25 lbs. of coal per hour to furnish each h. p. on the track. When we compare this with the 6.6 lbs. required under the present arrangement, the saving would be very little, if anything. One consideration in favor of stationary engines is the possibility of using cheaper coal than the locomotives require, but if this were the only advantage, it would obviously not be worth while to apply electricity to the elevated railroads.

There does not seem to be margin enough to work on, and it is only by assuming extreme figures against steam and in favor of electricity, that a material showing in favor of the latter can be made.

ON AN AUTOMATIC CUT-OUT FOR CHARGING SECONDARY BATTERIES.

BY GEORGE B. PRESCOTT, JR.

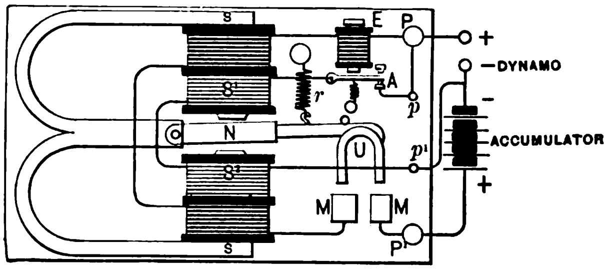
THIS instrument consists of a double coil, polarized electro-magnet, and armature, in which one coil automatically connects the charging dynamo to the battery whenever its E. M. F. exceeds that of the battery, while the other maintains such connection until the E. M. F. of the battery nearly approaches that of the dynamo. The polarization of the electro-magnet prevents damage by accidental reversals of the circuit current, whether such reversals occur suddenly whilst charging or otherwise.

In the accompanying schematic illustration S, S, represent the south poles of two powerful horse-shoe magnets whose opposite ends are united into a common north pole, which is extended by the soft iron armature, N. Attached at right angle to each of the south poles are soft iron cylinders forming the cores of electro-magnets, s1, s2. These electro-magnets are each wound with two coils, whose magnetizing effects coincide, one composed of a few turns of thick and the other of many turns of thin wire, the latter being superposed.

The thick wire, or main circuit ending at the binding posts, P, P1, includes the electro-magnet, E, and the mercury cups, M, M, the latter forming a "break" which is closed by the bent wire, U, carried on the end of the armature. The thin wire, or shunt circuit is completed to the binding posts, P, P1, through the armature and back stop of the electro-magnet, E.

By means of the spring, *r*, a bias is given to the armature, N, toward s1, as otherwise it would be attracted indifferently by s1, or s2, according as it happened to be nearer to one or the other. The armature is, therefore, normally against s1, and in this position leaves the main circuit broken at the mercury cups.

It will be seen by reference to the diagram that the thin wire coils act as a shunt about the poles of the dynamo. When the latter is "started up" its current flows through



PRESCOTT'S AUTOMATIC CUT-OUT.

the shunt coils in such a direction as to reverse the magnetism of s1, making it, therefore, a north pole, at the same time increasing the magnetism of s2, making it a still stronger south pole. The armature, N, is consequently repelled by s1, and strongly attracted by s2. The retractile spring *r*, is, however, so adjusted that it counteracts the tendency of the armature to move toward s2, until the E. M. F. of the dynamo has reached a certain predetermined limit. This limit must be, of course, an E. M. F. greater than that of the battery to be charged, and as soon as it is reached the armature moves over to s2, closing the break at M, M, and allowing the whole dynamo current to pass through the battery. The main coil now holds the armature; the electro-magnet, E, having become energized and broken the shunt circuit at A. As the battery becomes charged its E. M. F. rises, and when it nearly equals that of the dynamo (which it opposes, of course,) the current circulating in the main coils becomes too feeble to resist the spring, *r*, which therefore pulls the armature back to its original position against s1, and breaks the main circuit at the mercury cups. The same conditions would arise and the cut-out would act in the same manner should the E. M. F. of the dynamo fall off, from any cause, or disappear entirely as it would if the driving belt should break. In the latter event, however, the reverse current from the batteries might traverse the circuit before the retractile spring could act (commonly the case with ordinary cut-outs), but just here the action of the polarized magnet is utilized, for this reverse current makes a north pole of s2, and increases the south polarity of s1. The armature is thus repelled by s2, and attracted by s1, besides being pulled back by the spring *r*, and so, as before,

Digitized by Google

breaks the circuit at the mercury cups. The reverse current is thus rendered harmless by its own action.

When once properly adjusted the cut-out requires no further attention. It will connect the dynamo to the batteries whenever the dynamos' E. M. F. has reached the predetermined limit, and disconnect it whenever the E. M. F. falls below the limit and when the batteries become charged. It may be located with the battery at consumers' residence, and is particularly adapted to intermittent power.

WESTON LABORATORY, NEWARK, N. J., April 4, 1885.

RADIATION vs. ELECTROLYSIS.

BY FRANK C. LOCKWOOD.

Scientists—and doubtless many who are not yet worthy to be called scientists—have noticed the metallic deposit which sometimes appears upon the inside of the globes of incandescent lamps after they have been continuously in use for a considerable length of time. The cause of this deposit is, of course, well known ; it being nothing more than the result of the decomposition of the copper or carbon or both, but deductions therefrom have sometimes been hastily and erroneously made.

We have recently had occasion to examine a lamp which has been in use a long time in the premises of a large silver-ware manufacturing firm in this city. It is an ordinary 16-candle Edison lamp, and at present has almost the appearance of a solid globe of bronze, so great is the deposit of copper within it. The explanation, as we have said, is apparent ; electrolysis of the copper has resulted in the fourth condition of matter, and not, as ordinarily in cases of this kind, in the third or gaseous state. The peculiar effect is due in part to radiation and not simply to decomposition. This is demonstrated by the directions taken by the matter, and by the fact that the distribution has taken place from one point, which so far as can be judged, is one of the copper clamps holding the filament of carbon. It is also verified by the fact that from the top of the lamp to where the other clamp is situated a thin line of clear glass may be observed, following the line of the carbon filament and evidently protected by it from the deposit of particles proceeding from the centre of radiation. It is a somewhat novel phenomenon and we think on that account deserves notice. Aside from the elaborate experiments of certain physicists the often peculiar and sometimes startling effects of the fourth condition of matter have perhaps not received the attention they are justly entitled to. The study of these phenomena is at once entertaining and instructive, and undoubtedly will in time become more general than it is at present.

CREDIT TO WHOM CREDIT IS DUE.

WE are not in the habit of troubling our readers with complaints, when our esteemed contemporaries borrow our original articles, as they sometimes do, without giving the slightest intimation of the source from whence they were derived, but we must in fairness insist upon such extracts being credited, if at all, to their proper authors. We would therefore respectfully represent that the table of electro-chemical equivalents which was published in *L'Electricien* of February 7th, was prepared expressly for us by George B. Prescott, Jr., of the Weston Electric Light Co., of Newark, N. J., who should not be mistaken for the well-known author of *Electricity and the Electric Telegraph*. This table appeared on page 7 of the January number of THE ELECTRICIAN AND ELECTRICAL ENGINEER, and certain corrections thereof will be found on page 72 of the February number, to which we desire to direct the attention of all interested.

ABSTRACTS AND EXTRACTS.

REAR COLLISIONS ON RAILROADS.

WE call attention to reports of the occurrences contained in our imperfect record of accidents for October, 1884, from which it will appear that 17 out of 29 rear collisions therein noted were strictly tail-enders, which might have been avoided by the proper use of the simplest block signals, maintaining a positive interval between the trains which were following one another.

All of these events except one, so near as we can make out, were due to the bad dependence placed upon bad flagging. As nearly as may be gathered from the reports, at least four persons were killed, 31 persons were injured, 12 engines were wrecked, and 82 cars were destroyed or crippled in these disasters.

In attempting an estimate of the damages resulting from them we shall probably fall far short of the truth, because we have no details from which we can calculate the loss of traffic suffered during the blockade of tracks resulting from a disaster of this kind, nor the cost of clearing up the wrecks, nor the injury done to the tracks, nor the value of the contents of the cars which were destroyed or injured, nor the loss which always must ensue from a destruction of confidence in the safe management of the roads upon which these collisions took place ; but we have estimated these unknown quantities at the very moderate sum of $500 for each accident. The value of a human life we have taken at the rate fixed by law.

Our estimate of damage stands as follows :—

12 engines wrecked	at	$1,000	each	$12,000
82 cars wrecked	at	200	"	16,400
4 persons killed	at	5,000	"	20,000
31 persons injured	at	100	"	3,100
Conjectural damages, 17 instances	at	500	"	8,500
Grand total				$60,000

or about $3,530 for each tail-ender. From what we have personally seen of these misfortunes, we cannot regard this as probably too high an average.

Estimating the cost of a good block-signal semaphore at $75, the $60,000 which we have estimated these disasters to have cost would have furnished 800 stations with semaphores ; these stations being placed five miles apart, this outlay would have provided for 4,000 miles of railroad ; and, proceeding at this rate, in 30 months the entire railroad system of the United States might be equipped with suitable means of preventing this description of accident.

Or, looking at the subject in another way, if by the adoption of the very simple block system described in the *Railroad Gazette* of November 7, 1884, a railroad should escape *one* tail-ender of the average cost which we have estimated, it will have recovered the expense of equipping 47 stations, or at distances of five miles, as before, 235 miles of line. It is very clear from these figures, that a railroad with any business worth considering, can better afford the signals than it can the tail-enders. On many roads it would perhaps not be necessary to add one man to the staff ; on others it might require the addition of several night telegraphers, and on still other roads, where attention has not been paid to the advantage which may be derived from employing as agents at small stations persons who are also telegraphers, it might require the establishing of telegraph offices at points which now have to do without them. Yet, making the largest possible allowance for these contingencies, we feel assured that it would be better to meet the cost of them, than to suffer from accidents which are so clearly preventable by the adoption of the simplest precautions.—*Railroad Gazette*.

ARC-LAMP CARBONS.*

ALTHOUGH improved processes and enlarged experience must inevitably lead to greater perfection in the manufacture of carbons, they are not yet by any means satisfactory.

Digitized by Google

In commenting upon this subject the London *Engineer* says that the two greatest defects which arc lighting can have are flickering and noise. Variations in the amount of light are of secondary importance. If a lamp flickers, the defect is simply fatal. As a rule, flickering is not caused by a defect in the lamp, but by the imperfection of the carbons, or the improper manner of using them. It seems to be proved that, on the whole, the best results are got by using carbons about 10 or 11 mm. in diameter below and 12 mm. above, the upper carbon being, of course, the positive, with a current of 8 to 12 ampères, and an electromotive force of 35 to 40 volts. The h. p. in the first case will be $\frac{8 \times 35}{746}$, or ·37 h. p. In the latter case we have $\frac{12 \times 40}{746}$, or, say, ·64 h. p. This is rather too much for carbons of the stated size, and it will be found almost impossible to make the lamp burn steadily and without noise. The large current tears the carbon points to pieces. If it is still further augmented, flaming sets in, and the light is positively reduced instead of being augmented. Now, every carbon requires a special current and electromotive force which will give a better result than any other; and when the current is kept small, and the electromotive force moderately high, absolute steadiness may be secured.

The struggle to get the greatest possible quantity of light out of a lamp has ruined the reputation of many good lamps. No matter what the current may be, some carbons will never burn quietly, the reason being either that gases are occluded in the carbon, or that substances are left in it which will produce them. In estimating the good qualities of a carbon, the first thing to be considered is its conductivity; if this does not exist in a high degree, it must be rejected without ceremony, no matter how good it may be in other respects. It will become very hot when the current passes through it, and will rapidly waste, tapering away to a point from its proper thickness for a length of two or three inches. The carbon holder of the lamp may be burned, and much mischief done. We have seen carbons quite silent and giving out a magnificent light, which were worthless because of their high resistance. Attempts are made to get over the difficulty by coppering the carbons by the electrotype process, but the result is not satisfactory. No adequate explanation of the causes of want of conductivity or the reverse has ever reached us. Two carbons made by the same process, at the same time, and from the same materials, may be found, one of which will prove excellent, while the other will not conduct at all. So far as can be gathered, the conducting power depends more on the molecular structure of the carbon than on anything else.

Conductivity secured, the next thing to be sought for is silence and absence of flickering, and these can be had in only one way, namely, by purifying the coke in the first instance from which the carbons are made. The best material seems to be the linings of gas retorts; but this ought to be treated with caustic potash and carefully washed. This is not the place to go into the details of manufacture. We must content ourselves with general principles. The best carbons and the best lamps will give bad results if, as we have said before, the current is not just right; and one point, frequently neglected, ought to be insisted on, namely, that the speed of the dynamo shall be kept constant. The resistance of the arc varies continually. It is instructive to put a single arc lamp in circuit, and then watch the hand of an ampère meter. This will seldom or never be quite at rest. If the carbon is a bad one the hand will jump through comparatively large ranges, each sputter of the carbon being attended by a jump. When there are a good many lamps in series, a little overfeeding or a little underfeeding may considerably alter the resistance, and unless there is plenty of power and a good governor, the result will be unsatisfactory. Thus, for example, let us suppose that a little overfeeding takes place. The resistance is diminished, the quantity of current augmented, and more load is thrown on the engine. If it is properly governed it will keep its speed constant, and the lamps have a chance of recovering themselves. If, on the contrary, the speed falls off, the lamps will get worse and worse. It is only too often assumed that arc lights do not need regular speeds; but this is quite a fallacy. They want it quite as much as the incandescent system.

THE INTERCHANGEABLE SYSTEM.

Latterly considerable discussion has arisen as to when and by whom the system of interchangeable parts was introduced in mechanical processes. Inventors both in this country and abroad have been credited with the high honor; indeed, so many persons have been thrust into prominence as rightful claimants that the curiosity to know to whom the mechanical world owes its thanks and praises is whetted by the desire to see simple justice done. From all that can be learned it appears that sample guns with parts to interchange were made in France as early as 1717, and again in 1785, but for lack of machinery, presumably, attempts to reduce the feature to practical use failed. Eli Whitney, of cotton-gin fame, took up the idea in this country, and introduced the plan of filing the component parts to hardened jigs, by which an approximation was made to the uniformity system, but not sufficient to make them interchange without extra labor in filing, which was too costly for general use. Gen. Wade, of the United States Army, credits Hall, of Harper's Ferry and breech-loader-rifle fame, with the first successful attempt ever made in this or any other country to manufacture arms upon this principle. Hall's rifles, according to Gen. Wade, were manufactured under the supervision of the inventor, who introduced the system in 1827–8 of making all the parts of the arm interchangeable. But according to an extra census bulletin issued in 1882, or rather according to an official report published therein from the pen of Charles H. Fitch, the system was first carried out as a success at the United States armory, at Springfield, and that success was due more to Thomas Blanchard's invention than those of other persons. Blanchard's inventions were numerous and of great value. He brought out a lathe which would work to any given model placed before it, be it round, square, crooked or straight, and rapidly and exactly reproduce the original form every time. He also constructed an ingenious tool for mortising in the lock. No kind of glove could be fitted more closely to the human hand than did the mortise to the lock. In 1842 the armory at Springfield achieved the great triumph of merging individuality of parts in numbers, and all distinguishing marks of letters and numbers were discontinued at once and forever. Thus after a slow growth of twenty-three years in United States armories, or from September 6, 1819, the date of Blanchard's early patent, to 1842, the system attained its full growth and perfection. During these years there were two national and six private armories in the United States service employing first-class mechanics, and they nearly all contributed something; some new motion or some new process to the common result.—*Age of Steel.*

A TOWN ELECTRICALLY LIGHTED BY WATER POWER.

At Bellegarde, in France, M. Dumont, a manufacturer, has thrown a dam across the Valserine, a stream yielding 1,100 gallons per second, and affording, with 165 feet fall, at least 2,000 h. p. A 600 h. p. turbine drives, among other machines, 2 Gramme dynamos, the current from which is led by copper conductors on poles, to Edison incandescent lamps distributed about the town.

LITERATURE.

REVIEWS.

Electricity and the Electric Telegraph, by GEORGE B. PRESCOTT. Sixth edition, revised and enlarged, with 670 illustrations (2 vols). New York: D. Appleton & Co., 1885.

IN the first edition of Mr. Prescott's work, which was published in 1877, the apparent design was to cover with as much completeness as possible, the practical aspect of the mo ern electric telegraph, and, to a certain extent, to trace its historical development. A considerable share of attention was also devoted to a discussion of the various theoretical considerations upon which the operation of the different kinds of electrical and telegraphic apparatus depend. No work had hitherto been published in the English language designed to occupy precisely this field. The nearest approximations to anything of the kind were the excellent works of Dr. Schellen in the German and of Blavier in the French language. In the preparation of the original work Mr. Prescott followed pretty closely the general plan of Schellen's work, both as to the arrangement and the treatment of the subject-matter, and in fact much of the purely theoretical portion of the work was essentially the same as that of Dr. Schellen, which was conspicuous for its clearness, simplicity and admirable adaptation to the wants of students and investigators. Building, therefore, substantially upon the general lines of Dr. Schellen's work, Mr. Prescott extended, enlarged and amplified it by the addition of a vast amount of new and valuable material, relating especially to the details of the telegraph work in the United States and in Great Britain. At the date of the publication of the first edition, therefore, no other treatise could be mentioned at all comparable with that of Mr. Prescott, in respect to the variety and extent of information relative to the American telegraph system, which was then confessedly in advance of that of any other country in the world, whether judged by the actual amount of business handled in proportion to the cost of the working plant, or in the shortness of the average time occupied in transferring a communication from the hands of the sender to those of his correspondent.

At the date of publication referred to, the quadruplex system was scarcely three years old, the telephone was a feeble infant lisping its first accents, and the electric light was nothing more than a philosophic toy, or at most an interesting laboratory experiment. Eight years have passed since then, but how changed the aspect of affairs in the electrical world! Then the portion of the electrical field outside of telegraphy was comparatively insignificant; to-day telegraphy is only one of a number of important interests which have suddenly grown up, as it were, in a night, some of which threaten in the not distant future to overshadow it altogether.

The modifications which the American telegraphic system has undergone since the introduction of the quadruplex have been few and unimportant, and in fact it may be said that there have been no innovations introduced worthy of special note, unless the application of dynamic electricity to telegraphy may ultimately prove to be such. Nevertheless, the great demand for Mr. Prescott's work, which has already exhausted five editions, has been such as to justify him in making some revisions and adding a considerable amount of new matter to the original work—additions which have increased its bulk to such an extent as to render it advisable to issue it in two volumes, a change which has been effected without any increase in price.

In the present edition we observe that considerable new matter has been added, having to do with the quadruplex system. Descriptions and illustrations of some of the earlier attempts at the solution of this interesting problem, made many years ago in Germany, are given, while the practical telegrapher will find much of importance and value in the various modifications of apparatus which are illustrated and described, having for their object the adaptation of the typical or standard system to the almost innumerable special conditions which arise in the telegraph service under different circumstances. A chapter on the application of the duplex methods to submarine cables will be found of much interest. It contains descriptions of the systems of De Sauty and Harwood, and of Muirhead and Taylor. The French system of Ailhaud, which, however, is adapted only for short cables, is also explained and illustrated. The method of Mr. J. B. Stearns, which is employed on the Anglo-American cables between Newfoundland and Ireland, is not described, and in fact we believe no complete description of it has ever been made public. A new and valuable chapter on electrical measurement has been inserted, which is essentially the same in subject-matter and treatment as that which we have already referred to in our notice of the author's work on dynamo-electricity.

The remaining additions are mostly of a miscellaneous character, relating to such subjects as electric call-bells, the Western Union time service, Siemens's electric furnace, Maxim's automatic fire extinguisher, Brooks's underground telegraph system, Lewis's improved insulator, and D'arlincourt's relay. Mr. Delany's interesting system of synchronous multiple telegraph is described, and there is also a discussion of the comparative advantages of the different forms of electro-magnets, extracted from Du Moncel, which cannot fail to be of frequent use to practical electricians.

On the whole, the improvements which have been made in the present edition may be said to add greatly to the value of the original work.

The mechanical execution of the volumes is admirable in every respect. The typography is clear and tasteful, the engravings are executed in the best style of the art, the paper is of good quality and not too thick, and the binding neat and substantial. We mention these points for the reason that it is becoming of late too much the fashion for publishers to send out books which are deficient in one or more of these particulars, a fault which it is fair to say is seldom found in scientific works bearing the imprint of Messrs. Appleton & Co.

Transactions of the American Institute of Electrical Engineers. Vol. I. May-October, 1884. New York: Published by the Institute (1885).

THE Institute of Electrical Engineers, which was organized in the spring of 1884, held its first general meeting at Philadelphia during the International Electrical Exhibition which was given under the auspices of the Franklin Institute in October following. The meeting was a very satisfactory and successful one, and a number of papers of interest were read and discussed by the members and others present, most of which have now been collected and published as volume I. of the "Transactions of the American Institute of Electrical Engineers."

This volume, which has just been issued by the secretary of the Institute, is prefaced with a brief historical sketch of the organization of the society, but the bulk of it is occupied by the papers and the discussions which arose from them at the meeting.

Professor E. J. Houston, of Philadelphia, has a short paper describing certain peculiar phenomena in an incandescent lamp exhibited by Mr. Edison at the exhibition. A discussion ensued, in which Mr. W. H. Preece and Mr. N. S. Keith each took a prominent part, but no very definite opinions were ventured as to the cause of the phenomena. Mr. Preece expressed his intention to make a careful investigation after his return to England, and the results of his labors in this direction will be found in his paper which we republish in our present issue.

Mr. W. M. Callender's paper on underground wires, although particularly devoted to an exposition of the merits of his own wares, is, nevertheless, by no means wanting in information of general value. Mr. Preece remarked that from his experience as an officer of the post-office telegraphs, he could confirm all that Mr. Callender claimed for his material.

Perhaps the most suggestive and interesting paper in the collection is one by Rowland R. Hazard, under the title of the "Scientific City Street,"—not that there is anything intrinsically novel in the plan proposed by Mr. Hazard, but that the details have been carefully thought out by him and embodied in a definite working plan, of which a handsome lithographed drawing in four colors accompanies the paper, illustrating the practical application to such a street as Broadway, New York. The plan embodied in Mr. Hazard's paper is worthy of far more careful consideration than it is likely to receive at present, although nothing can be more certain than that an ultimate reconstruction of Broadway will inevitably be forced upon us. That in such case it will be rebuilt upon substantially the plan proposed by Mr. Hazard we have no manner of doubt. The scheme may be briefly described as a continuous arcade beneath the carriage way, affording room for four parallel lines of railway, two on the outside for way trains and two in the middle for through trains. Between the arcade and the curb on each side is a space four feet six inches in breadth, which may be made of any required depth for the accommodation of pipes and wires of every description. The space underneath the sidewalks is reserved for vaults for the accommodation of adjacent buildings. The trains on this subterranean railway system are of course designed to be propelled by electricity. Professor C. F. Brackett, of Princeton, N. J., presented a brief but suggestive paper, giving an account of his method of experimentally investigating the characteristics of the dynamo machine by means of an exploring coil, whereby the value of any point in the magnetic field may be instantly determined. An excellent paper, in the characteristic and well-known style of Thomas D. Lockwood, on the subject of earth-wires, was presented by him. After a thorough discussion of the subject, the author reaches the conclusion that no earth-wire and plate should offer a resistance of more than 10 ohms, and that earth-wires at opposite terminals of a circuit should always be composed of similar metals; conclusions which may be said to possess less intrinsic originality than the methods of investigation by which they were reached. S. J. M. Bear, of Iowa, gave an account of a curious experiment in the transmission of telegraphic signals through water without the aid of wires.

We have no room to give an adequate summary of the exceedingly interesting paper of E. P. Thompson on the chemistry of

Digitized by Google

the carbon filament, in which the peculiarities of the various processes employed by Weston, Edison, Swan and others are discussed and compared. The account given by the author of his own investigations in the manufacture of carbon filaments from animal matter will attract special attention. It is a matter of regret that the discussion which followed this paper elicited so little additional information of importance from those present, some of whom were apparently well qualified to impart it.

Finally, we have to notice a forcible paper on the needs of the Patent Office and the relations which it sustains to inventors, by C. J. Kintner, principal examiner of the division of electricity. Mr. Kintner's paper is but a reiteration of the considerations which have often been urged in our own columns, as to the insufficiency of the accommodations and the utter inadequacy of the present numerical force of examiners to cope with the rapid increase of applications, whereby the most vexatious and exasperating delays are caused, and great consequent damage inflicted upon the interests of patentees and patent owners. He has, however, set forth the difficulties under which the examining corps are compelled to labor, in a manner calculated to convey a particularly vivid idea of them. In fact the feeling which will be uppermost in the mind of any candid person after reading this paper will probably be one of wonder that the work is done half as well as it is, especially in the electrical division. It is gratifying, however, to be able to say that, by some means or other, an improvement has been effected since the advent of the new administration, for the last month has certainly shown a visible acceleration in the movements of the machinery of the Patent Office.

Taken as a whole, the contents of the first volume of transactions are exceedingly creditable to this vigorous young society. The publishing committee have performed their work in an eminently satisfactory manner, and it is only to be regretted that the volume is not consecutively paged, owing to circumstances beyond the control of the committee, a defect which we are assured will not be permitted to occur in the case of subsequent volumes.

QUESTIONS AND ANSWERS.

[62.]—**A. J. N.** We are always pleased to receive such information as you gave in your letter of April 15th, and shall be glad to hear from you again.

[63.] **Battery for Electric Motor.**—J. H. S., St. Louis, Mo., says: I am making a motor on the plan recently described by Mr. Chaster, but of twice the dimensions, the armature being 6 in. long and 3 in. in diameter. What is the best size and amount of wire to use with the gravity battery, say 10 or 15 cells 6 in. by 8? **Ans.**—It is impossible to run anything larger than a toy motor with the gravity battery. It is not at all adapted for the purpose. The only battery suitable for operating a motor is a bichromate or a nitric acid battery, respecting which we design to give full information at an early day.

[64.] **Electric Circuits without Wires.**—C. F. W., N. Y., says: 1. Please inform me if there is any way of completing a telegraphic circuit without a continuous wire. 2. How many ohms resistance and how many cells of battery would be required to operate a telegraphic line from Jones to 44th st.? **Ans.**—1. No practical means has yet been discovered of transmitting signals for any considerable distance without wires. 2. Use a No. 11 iron wire, instrument of about 50 ohms resistance, and 8 or 10 cells of gravity battery, or its equivalent.

[65.] **Construction of Electric Motor.—Working Capacity of same.—Batteries.**—C. N. of Toronto, Ontario, says: 1. I wish to construct an electro-motor similar to the one described in the ELECTRICIAN AND ELECTRICAL ENGINEER. Can the field magnets be made of 2½ in. iron gas pipe, the poles to be fastened to the inside and afterwards bored out to the required diameter? Such magnets would hold nearly as much wire as the pattern described while the iron would be of better quality. 2. Will the motor run a small screw cutting lathe with a battery of 8 bichromate cells? 3. Is there any battery which after once setting up will require any further attention until fully exhausted, develop no local action when not in use, and only require switching on when the motor is to be used? 4. How can I anneal cast iron? **Ans.**—1. The machine will be less efficient with the hollow cores. It is possible that this might be compensated by the better quality of iron but we think it doubtful. 2. We think so. 3. No. Such a battery would ensure a fortune to its inventor. The nearest approach to it is the bichromate battery, when so arranged that the plates may be withdrawn from the solution by a windlass when the battery is not in use. 4. The castings should be of charcoal-iron of the best quality. They are first scoured to free them from sand and scale and then packed in an iron box with fine iron scales from a rolling mill, which is closed at the top by a mixture of sand and clay, and all the cracks luted to prevent the admission of air. The box is then subjected to white heat in the annealing oven for several days, and allowed to cool very gradually. This can be best done at a malleable iron works.

NEW YORK AND VICINITY.

Electrical Power not yet "on Tap."—The Van Depoele System in the East.—Proposed Retirement of Mr. Cyrus W. Field from Active Business.—Bids for City Street Lighting.—The Gas Consumers' Association.—Subterranean Wire, Work.—Bankers and Merchants' Bonds.

THE mechanical trade papers, and a great many of our citizens, are rather skeptical about the successful adoption of electricity for traction purposes on the elevated railways.

In the early stages of electric lighting, much was said about the utilization of the central plants for distributing power during the day. This was to be an important feature especially of the Edison down-town system, as it was well understood that the average demand for artificial light in the lower wards of the city is very limited. So far there have been no active indications of a desire to occupy this field, although an electric fan, which occupied a prominent position at the Philadelphia exhibition, has been hinted at as a probable channel into which electrical energy might be diverted. This seems to be very little fire for so much smoke, and as there is certainly in Nassau street and Maiden lane a fine field for such light power as it was proposed to furnish, we think it would certainly give a better business appearance if an effort was made in this direction, before undertaking to supplant steam on the elevated railways.

There is a plan on foot for the invasion of Eastern territory by the Van Depoele Electric company of Chicago, the first step of which appears to have been the organization of a company at Elizabeth, N. J., with a nominal capital of $250,000, to exploit the various electrical devices which are manufactured under the Van Depoele patents. It has been announced that a tower to light the bankrupt city would be erected near the Union depot, but as yet there has been no announcement as to where the cash was coming from. If the city is to be lighted as an advertisement of the tower system, the tax-payers will no doubt be pleased.

It has long been the expressed intention of Mr. Cyrus W. Field to retire from active participation in business upon the completion of his fiftieth year of service in the commercial world. Having reached this period within the past few days, he has severed his official connection with the various companies with which he has been associated, including the Manhattan Elevated Railway and Western Union Telegraph companies. He retains his financial interest, however, in the enterprises in which he has been prominent. His place in the executive committee of the Manhattan Elevated company has been filled by his eldest son. As soon as Mr. Field has wound up his pending business he will start for Europe, and after a brief stay in London, in connection with some legal matters there, will start on a trip around the world.

The bids for street lighting for the coming year by the local Brush and United States companies, were the same as last year, 70 cents per night for each lamp—$255,50 for one year. When the contracts are made for the work, their overhead wires will probably not be disturbed by the "underground" commissioners until after their terms expire.

The disgruntled gas consumers have organized under the title of the Gas Consumers' Association of the State of New York. Its objects are announced to be as follows: To obtain, preserve, and circulate information of value to gas consumers and the public generally; to secure adequate inspection of meters, so that consumers may get what they pay for, gas being the only commodity which is not habitually measured by standards established and maintained by public authority; and to impose upon companies furnishing the public with light such just restrictions as are recognized elsewhere as necessary for gas and other corporations exercising a public franchise, where the interest of consumers is not protected by the law of competition, and where the individual citizen cannot successfully maintain his rights against large organizations.

John H. Sherwood, Jackson S. Schultz, William D. Garrison, Sheridan Shook, Robert M. Strebeigh, Francis B. Thurber,

Digitized by Google

William H. Webb, Theodore Moss, Henry M. Smith, and Frank S. Gardner, are the charter members.

With the advent of fine weather, the work of placing the telephone wires of the city underground has been renewed. Broadway above 21st street was opened on the 19th, and the pavement replaced before Monday morning. The wires are to be run as follows from the 21st street exchange: To the corner of 4th avenue and East 21st, 217 wires; to corner 6th ave. and West 21st, 271 wires; to corner Broadway and 19th, 205 wires; to corner Broadway and 23d, 307 wires; making a total of about 1,000. This of course, is but a small fraction of a single system of overhead wires.

The claim of Mr. A. G. Day against the Bankers and Merchants' Telegraph Co., was secured by mortgage bonds for $334,000 par value. He obtained judgments for $18,000 against the company in Illinois, which with the bonds were subsequently assigned to Edward S. Stokes. An injunction was granted by Judge Donohue about two months ago restraining Stokes from enforcing the judgments or disposing of the collateral. On the ground that the bonds have a market value of only 5 per cent. of their par value and are continually depreciating, thus lessening the security for his judgments, Stokes obtained from Judge Barrett, in Supreme Court Chambers, an order permitting him to sell them.

PHILADELPHIA.

The Latest Scheme to Revolutionize Telegraphing.—What the Hathaway Printer is Expected to Accomplish.—The "Underground" hearing at Harrisburgh.—The Fottrell Cable for Subterranean Work.—Permission Granted for an Electric Railway in the Park.

"A NEW application of electrical science has been made here that *promises* to go far towards revolutionizing telegraphy and supplanting the telephone in popular favor."

According to this statement, all that is necessary for one to do to become a full-fledged, strictly first-class telegrapher, is merely to learn to write on a type-writer and presto! it will be the merest play for any one to transmit or receive messages—perhaps. If this new "wonder" is capable of doing all that is claimed for it, what is to prevent girls, clerks, expressmen, station agents, carpenters, car drivers, *et al*, from ousting the expert Morse operators and filling a long felt want? Clearly, nothing. For reasons best known to the company controlling this most important invention, its operations have until now been kept a secret. The office and operating rooms, at 327 Walnut street, have been carefully guarded against reporters, and the men interested have been as close-mouthed as if it had been a political mystery, instead of a step in progressive science that they were concealing.

The distinguishing features of the new system—which takes its name from the inventors, Messrs. George M. Hathaway and James H. Linville—are the entirely novel transmitter and receiver employed. Those two instruments, although put near together here upon a table, have between them about a hundred miles of ordinary telegraph wire coiled about the room, through which their connection is made. In point of fact, the transmitter and the receiver are exactly alike, the same machine serving for either use as required. Its front is almost the same as the key-board of a caligraph or type-writer, the letters of the alphabet and the numerals standing up on elevated keys. There is nothing extraordinary in the printing mechanism, but the novel principle of the instrument is, that the different characters are printed by current pulsations of various strengths.

One of the gentlemen connected with the new enterprise said: "The distinctive advantages claimed by this system over all other telegraphic, telephonic and type-writing instruments are in its simple and inexpensive construction, and the ease of operating it. Any person who can read can transmit and receive messages through it as correctly as could the most experienced expert using the Morse instrument. It is as rapid as it is accurate, and all messages by it being automatically printed, both at the point of transmission and that of reception, they can be received with safety and reliability in the absence as well as in the presence of the recipient. The recording of messages at both points precludes all questions of errors in transmission. It cannot be read by sound, and is consequently the only method for preserving privacy in electrical communication. It is at once a stock indicator, telephone and type printing telegraph. For railroad and express companies, bankers, brokers, merchants and all commercial purposes—it being adjustable to any system of wire communication and capable of working with any number of tributaries—it is of inestimable value. It is not a verbal telephone, but will supersede that instrument by silently and rapidly recording all messages upon paper. There are no formidable complications in its construction, and it is regarded by expert electricians as a wonderful achievement."

Greater confidence could hardly be shown by capitalists in a new invention than that demonstrated by the company of Philadelphians who control the Hathaway patents. They have issued $2,000,000 of capital stock in 200,000 shares, but no shares are for sale, even at par. They propose to hold all as an investment. The officers are: president Thomas Cochran, president Guarantee Trust and Safe Deposit Company; vice-president, J. H. Linville, C. E.; treasurer, Thomas T. Butcher; secretary, Wm. H. Wile, secretary Southern Maryland R. R. Co. Only territorial rights are to be disposed of.

At Harrisburgh further arguments on the underground wire bill were heard by the Senate Judiciary General Committee on the afternoon of the 14th, and Samuel B. Dixon, counsel of the Brush Electric Light Co., made his main theme the unconstitutionality of the bill unless it be amended to provide for compensation for the wires, poles and other property proposed to be taken. Henry Metzgar, of the Bell Telephone Co., of Pittsburg, and A. J. DeCamp, manager of the Brush Electric Light Co., of Philadelphia, presented an array of facts and figures designed to show the impracticability of the bill. Manager Palmer, of the Brooks Underground Co., spoke for the bill, pointing out many instances in which buried wires have been and are now being used with success.

I have in my possession several pieces of a cable manufactured by Mr John Fottrell of this city, which appears to be admirably adapted for underground work. The material used is extremely cheap, waterproof, and very durable, the effect of the earth being to harden and preserve it. Several tests of this cable have been made by practical electricians. Mr. George W. Porter, of the Western Union in this city, tested it and found it perfect—not getting the slightest deflection through an Elliot galvanometer. Mr. George A. Hamilton, electrician of the Western Union company in New York, also tested it. He found no leak in it, but thought the specific insulation too low for general telegraphic purposes. Mr. Fottrell has been a close student of chemistry for years. He has also been in the telegraph business for a long time and ought to know something about such matters. One of the pieces in my possession has been buried in the earth for eleven months and is better to-day than when put down. It would be just as easy to make this cable with a high as with a low insulation.

At a meeting of the Electric Committee of Councils the ordinance of the Northern Electric Light Co., granting permission to erect poles and stretch wires for electric light purposes on Frankford avenue, Kensington avenue, Norris street, and other streets in the upper section of the city, was amended and ordered to be reported to Councils with a favorable recommendation.

Park superintendent Thayer reported favorably yesterday to the Improvement Committee of the Park Commission, an application to build an electric railway in the Park, made by the Bidwell Electric Motor Co.

PHILADELPHIA, April 18, 1885.

CHICAGO.

Rapid Increase of Incandescent Lighting.—Isolated Plants Among the Theatres.—Proposed Substitution of the Electric for the Cable Railway.—Explosive Subterranean Conduits.—More Rest for the Firemen.—The Baltimore and Ohio Subterranean System.—A New Telegraph Company.—Telephone Affairs Quiet.—How to Avoid Shocking Results from Dynamo Circuits.

THERE are fluctuations in electric lighting as in other enterprises. The dear public wants more and better light than gas jets furnish. Prime cost is, of course, an item worth considering—but the extra outlay has its compensation. Convenience, health and cleanliness weigh down the scale beam in the argument, and the public says "hang the expense, give us more light." The arc was first in the field, and paved the way, and the more modest glow lamps followed suit. Each has its place for which it is best fitted, and while the first has partially occupied its field, the lesser shiner has just begun to assert itself in a more extended way, while the former is taking a comparative rest, for a short season.

The United States people have lately put an extensive plant in the post-office portion of the government buildings here; and, by the way, despite the defeat of the Republican party in November, these seem to burn just the same under a Democratic administration. The same company are wiring large plants in the Home, the Northwestern, and the Royal Insurance buildings, the Mahler building and the barber shops of the Palmer House. In these several plants there is a total of about 4,270 glow lamps. The Edison people too are full of work, wiring the new Board of Trade building, adding to the Pullman building plant, and the county buildings at Wauwatosa, near Milwaukee, and will soon be wiring the city buildings and the two tunnels from the south division to the west and north divisions of the city. This latter plant will consist of two engines and four generators which will be placed in the basement of the city buildings, with a capacity for 1,500 lamps of 16 c. p. Of these about 300 will be distributed between the tunnels, the remainder in the corridors and various offices of the city building. It is proposed to light only a portion—about one-third—of the tunnel lamps during daylight, the entire number

Digitized by Google

being in use at night, while an average of three hours per diem will be the use of those in the building. Advertisements for bids were published early in the past winter, and the Edison company made proposals for furnishing the plant in accordance with the above data, for $41,375, and the council at the regular meeting of the 30th of March, ordered,

"That the Controller is hereby directed to enter into a contract with the Western Edison company, in accordance with the proposition of the said company, dated Dec. 26, 1884, in regard to lighting the buildings of the city, for the sum of $41,375."

The city officials, whose duties require artificial light to a greater or less extent, are as tickled as a boy with a new top, at the approaching release from the thraldom of gas. As one of these remarked to the writer, "This light is like fresh eggs compared to the kind that are only fit for scrambling, when placed alongside of gas. A gas plant is a bad egg all the year round—a bad color, pollutes the air, and——smells."

Then again McVicker's theatre is to be lighted with incandescent lights. So too the new Chicago Opera House; and the present Grand Opera House has lately blazed up with glow lights. This last is a Mather-dynamo-Perkins-lamp plant, and makes a very pretty showing indeed. A stage trick accompanied its inauguration. On the night of its debut, the auditorium was lighted up as usual with gas jets. All being ready these were extinguished, and electric lights substituted. The audience, at first astonished and bewildered, then pleased, saw the joke, and broke into the most uproarious applause, indicative of their approbation. The management look upon it as a grand and complete success, and it was the more acceptable, as it was not expected save by the minority.

When the plants mentioned shall have all been completed, Chicago will have nearly all her finer places of amusement lighted by this force which cheers but never vitiates, to wit: Columbia (*nee* Haverly's), McVicker's, New Chicago, The Grand, The Academy theatres, while arc lights hang before or within the Standard, the People's, Hooley's, several of the museums, and most of the better skating rinks, and the panoramas of Gettysburg and Siege of Paris.

Chicago doesn't propose losing her place in the procession in another direction. As she was foremost in the grip car enterprise, and prefers to lead rather than follow like a slow coach, *that* is beginning to be thought old fogyish, and it is now suggested that something better must take its place. So parties have come to the front with a proposition to give us an electric railway. The proposed route is from Adams, on State street, along this latter street to 63d, with a lateral branch on 43d from State street to the Stock-yards. The company proposes to pay for the right of way over this distance, which is something more than eight miles, $10, $5, and $2, per foot, according to locality, to owners of property along the route. Petitions are being circulated, the statutes requiring the consent of a majority of land owners, before any further steps can be taken, and it is believed that the proposition will be accepted by those most interested. The company is pledged to warm their cars, which will be a great point gained, if we are hereafter to experience such weather as was furnished by the signal service last winter, and further, the cars are to be electrically run, above the street grade, so as not to interfere with road traffic proper. Once this sort of transportation succeeds here, schemes for elevated roads will be as plenty as slivers in a lumber yard, throughout the city, and enough horse car stock, rails, cars, etc., will be for sale to supply any number of new settlements throughout the West cheap. If consent is obtained, the present enterprise will be in operation by next winter.

Attention has repeatedly in these columns been called to the fact, that very many of the underground systems in vogue, are faulty in that they are leaky not only to water, but to sewer and burning gas as well. Chemistry tells us that ordinary burning gas, when mixed with atmospheric air is highly explosive and dangerous when ignited. In other places besides Chicago this fact has been practically proven a sufficient number of times to hint at the necessity of doing better work in that line. The last practical joke of the burning gas factor here was played upon Charley Summers, the electrician of the Western Union, and Mr. A. Brotherhood, the company's engineer, who came near being seriously, if not fatally injured by an explosion of this nature from one of their underground conduits. On the heels of this, and by way of variety, Mr. W. C. Hopkins, superintendent of construction for the Postal company came near losing his life from sewer gas, while on a round of inspection, at one of these equally philosophically arranged death-traps.

Prof. Barrett has come to the front with another improvement in our already excellent fire alarm system. Heretofore, at any night alarm, all the fire department were roused from their beds, and stood ready to turn out, regardless of the locality whence the alarm came. Now, as a majority of all the engines and other apparatus is not needed at any one fire, to be routed out, in some instances, several times between taps and reveille was a hardship to which the kind-hearted professor had given much thought. The result of all this cogitation has been the introduction of a switch in the houses, which, when the men turn in at night is thrown over, cutting out all the alarm bells, clothes ropes, apparatus, etc., leaving the register alone in circuit. The man on watch knows by the box number, whether that particular company is wanted. If not, the men sleep in peace, but if they are, he turns the switch, and all hands are automatically called, as before. The result is highly satisfactory, for every man knows now, when called, that he is wanted, and they "govern themselves accordingly," as President Morrison remarked before the late convention here. But the horses, who seem never to sleep, show by their nervousness, although they are locked in, that they understand the call, and evidently wonder why they are not allowed a chance to race for the wagon pole.

The Baltimore and Ohio folks are plowing through Lasalle street with an underground system, the first of its kind here, which consists of a plank trough, about eight inches wide, and four deep, open at the top, which is laid at the bottom of a trench. Into this is poured asphalt and sand, a sort of fine concrete bed. Upon this is laid three two inch wrought iron pipes, which will receive Patterson, Clark and kerite cables. Over these pipes to the level of the sides of the trough, hot asphaltum is poured, and the pipes are thus protected from oxidation, and any minute leaks there may be, are effectually closed. Neither sewer nor burning gas it is claimed can reach the pipes, and water is thoroughly prevented from reaching them. Now, if condensed moisture will let the internal arrangements alone, it looks as if this should be a very nice sort of conduit. Time will show—and nothing but time is a proper insulation test, we all know.

E. B. Purcell, of Manhattan, P. I. Bonebrake, J. R. Mulvane, Joab Mulvane, and N. L. Gage, of Topeka, Kansas, have organized a company for the construction of a telegraph line from Topeka to the Pacific coast, at San Francisco. J. R Mulvane is the president, and P. I. Bonebrake secretary of the organization, which is said to be on a sound financial basis, and to have all the business vim and other qualifications to insure its success. When the sequel is reached it will probably show that this is a connecting link in some one of the many rivals of the pugnacious Ancient and Honorable company, whose initials were once interpreted to mean *W*-hip *U*-*Too*-*C*-ully.

Telephone matters are as quiet as owls at noon. The Central Union has declared its 5th dividend, of 1½ % payable on the 25th, and its stocks are a shade better therefor. Should the promised continuance of these quarterly dividends materialize there is no doubt the stock will reach par once more. Everything is reported in good shape, and prospects bright for the future, and there really seems no reason why such a state of things should not continue.

The Wisconsin company comes to the scratch every ninety days, and pays its quarterly 2 % ten days after the close of the quarter. This sort of thing has become chronic up there, and stockholders don't care a continental whether notice of dividend reaches them or not—they can always bet the check will, when the day comes.

A little episode in electric lighting, which came to my notice a few days since, deserves to be displayed as a cautionary signal for the benefit of the fraternity. In a large manufacturing establishment in this city, goodly quantities of galvanized iron wire are used, and the storage room for this has been in a dry basement, directly under an arc lamp in near proximity to the dynamo, in the same room. On the occasion referred to, the dynamo was running, and the lamp for some reason refused to burn. The party in charge, mounted the pile of wire, which consisted of many tons, and immediately upon touching the frame, received a decidedly sharp shock. The insulation of the circuit at the time exceeded the required limit, 1 megohm, and the only explanation of the phenomenon which seems to answer the requirements of the question is that the wire assumed the role of condenser and charged through his body. If this theory is correct, additional precaution should be observed in handling live circuits in close proximity to insulated columns, pipes, frames of metal, etc., for an accidental contact with one of these while handling a lamp or carbon might prove harmful if not fatal. Perspiring hands, damp feet or clothing are often quite an important matter, materially affecting the conductivity of a derived circuit, and the closer one who has charge of a dynamo circuit sticks to what has been sometimes stigmatized as "granny's rule," of "one hand in your pocket and think twice before you touch it," the better for him.

CHICAGO, April 15, 1885.

BOSTON.

More Objections to Increasing the Bell Telephone Capital.—Legislative Examination of the Books.—Discrimination against Telephone Subscribers.—Mr. McAdie on Atmospheric Electricity.—A Life Saved by Overhead Wires.—An Attempt to Prevent Telegraphic Errors by Law.—Electrical Photography in a Theatre.—The Martin Automatic Fire-Alarm System.—The Boston Telephone Exchange.

A MEETING of New England and Erie Telephone stockholders was held on the evening of March 23d in Lowell, the object of

Digitized by Google

which was to send a representation to appear before the legislature to remonstrate against the petition of the American Bell Telephone Co. for permission to increase its stock. A committee was appointed to go before the legislature and present the remonstrance. The chairman of the meeting was E. Lamson, and L. S. Adams was secretary. The Mr. Lilley who has been so conspicuous before the state committee was present at this meeting, and informed those present of the status of the matter.

The sub-committee from the legislature has been examining the books of the Bell company, who answered many of the questions proposed under protest.

The committee on mercantile affairs has agreed upon the following bill to prevent discrimination by telephone companies:—

SEC. 1. Any person or corporation owning, controlling or operating a telephone exchange or service in this commonwealth shall, on application of any telegraph company, furnish the telegraph company so applying with the use of a telephone or telepnones and telephone service and connection with their respective exchanges, and the subscribers thereto without discrimination between telegraph companies as to such connection, service or use of instruments furnished or charges therefor.

SEC. 2. Any person or corporation using, controlling or operating a telephone exchange or service in this commonwealth shall, on application of any individual or corporation and the tender of the charges or rental sum usual or customary for the class of service required, without unreasonable discrimination for the same class of service rendered, furnish such individual or corporation so applying with the use of a telephone and telephone service and connection with their respective exchanges and the subscribers thereto, provided that the individual or corporation applying will secure the rights necessary to make the connections applied for, and pay to the telephone company in advance a sufficient sum to cover the actual cost of the extension, if said extension is beyond one mile from any main exchange circuit of the said telephone company applied to.

SEC. 3. Any court in the commonwealth having equity jurisdiction shall, upon petition of any party in interest, enforce the provisions of this act by any suitable process or decree in equity.

SEC. 4. This act shall take effect upon its passage.

April 7th the committee had another hearing in the matter of supervision and regulation of telephone matters, Col. J. H. Benton for the petitioners and Geo. A. Bruce for the Bell Telephone company. Col. Benton made an argument and cited decisions to show that the state had the power to do what the petitioners asked for. Mr. Bruce preferred to postpone his reply until the committee considers the matter of direc ly fixing telephone charges

Mr. Alex. McAdie, of the U. S. Signal Service, spoke before the Boston Scientific Society, March 10th, on "Atmospheric Electricity." The speaker asked what proof there is of atmospheric electricity, and answered himself as follows:—1st. We have the aurora and its manifestations similar to passing electricity through rarefied air. 2d. The auroral energy acts on ferruginous matter like an electric current; telegraph lines and all forms of electrical apparatus are affected. 3d. If this energy encounters resistance it is converted either into heat or light. 4th. Certain bodies, like sulphate of quinine, will fluoresce under its action. The effect of atmospheric electricity on dust or haze was shown by an experiment of Dr. Lodge. An inverted goblet was filled with smoke; a current being sent through, the air rapidly cleared. This is supposed to explain the so-called clearing of the air by a thunderstorm. Lord Rayleigh's experiment of influencing the lines of flow and character of a fine stream of water was then shown. A piece of electrified sealing-wax being held near a thin stream of falling water, it was visibly deflected. Rayleigh conducted the experiment on a much larger scale, and although his piece of sealing-wax was seven or eight inches from the water, yet it was found to be covered with a film of moisture. This experiment affords an explanation of the rapid growth of a thunder cloud. The cloud acting in a similar manner to the sealing-wax, attracts the particles of water in the air.

Let us score one, and a good one, for overhead wires. At the severe and stubborn fire in Boston, March 24th, while Chief Webber, of the fire department, was directing the work of the firemen on the roof of an adjoining building, he tripped and plunged headlong, and but for his fortunate grasp of a telephone wire he encountered on his way down to the street, he would undoubtedly have been instantly killed.

Mr. Dunbar, for the legislative committee on the judiciary, reported a bill to secure greater care in the transmission of telegraphic messages. The bill provides that all persons, associations and corporations engaged in the business of transmitting or receiving telegraphic messages for hire shall be liable and responsible for all damages caused by their negligence, or that of their servants or agents in transmitting, receiving or delivering such messages, notwithstanding any contracts, written or oral, to the contrary.

The stockholders of the New England Telephone & Telegraph Co. have received notice of the annual meeting, to be held at the company's office, 144 Greenwich street, New York, May 4, 1885. The transfer books of the company are closed from April 4 to May 4, 1885.

The Suburban Telephone Co. has declared a dividend of 2½ per cent. This is the dividend announced in January as likely to be paid in April. The money is derived from the payment of a loan to the Erie Telephone Co.

At the Bijou theatre, April 10th, a scene not down on the bills took place. At the close of the first act, Mr. H. B. Lonsdale announced to the assembly that a photograph of the house would be made, and after three attempts a successful negative was obtained. Mr. Conly was the photographer. All of the Edison lamps ordinarily used were supplemented by 15 of the American company's, the whole illuminating power being estimated as 40,000 candles.

The Martin Automatic Fire-Alarm Co. have recently introduced their system throughout the immense establishment of Jordan, Marsh & Co. The committee on tariff rates of the Boston Tariff Association voted to make a reduction in the rates of insurance of 15 per cent. of the gross insurance premium paid by Jordan, Marsh & Co., on account of the introduction of the Martin system. It possesses many features of novelty. It gives instant notice of all disturbances and accidents to itself, indicating by separate and distinct signals the character of the interruption, a broken wire, a weak battery or a ground, so that the apparatus may be repaired at once. It also gives a distinct and separate alarm for a fire, or any undue heat in any part of the building protected.

The Boston Telephone Exchange people are now using the new multiple board system very successfully. Mr. Theo. N. Vail, general manager of the Bell company, has made the operating room of the exchange very attractive by placing therein a high semicircular stand for flowers, and filling the same with a choice selection of plants, some of which are in bloom most of the time.

BOSTON, April 18, 1885.

NEW ORLEANS.

The Exhibition Adopts a Half-Rate System.—Where the Finest Night View May be Had.—Electrical Hotel Fittings.—The Contract for City Lighting.—Proposal to Light the City for a Term of Years.—Arrival of the Baltimore and Ohio.—Progress of the Opposition Telephone Company.

SINCE the first of April the admission to the Exposition after five o'clock P. M. has been reduced to twenty-five cents, and as a consequence there are now more evening visitors than of old. However, it would require the number to be still vastly increased to justify the great outlay that has been made in electric lighting.

The finest view of the buildings and grounds, at night, is to be had from the upper deck of a steamboat out in the river. Visitors who failed to obtain that view certainly have missed a most enchanting scene.

This city must have been looked upon as a "mine," by electric companies of all kinds, this winter, and they have "worked" it with a will. New hotels of all sizes and styles have required bell outfits. The great Exposition hotels—"The Windsor" and Hotel Royal were fitted up by the Western Electric Co. Hotel Royal has a very unique light plant consisting of a 300-light Edison machine and a 16-light Jenney dynamo, both driven by an Armington-Sims engine. The St. Charles Hotel is equipped with a 150-light Edison dynamo, furnishing lamps to the rotunda, halls, parlors and offices on the first floor. This is the third season of this installation, however. The Jenney company has also sold to the "Battle of Sedan" a plant of 30 lamps and a dynamo, which has successfully illuminated the panorama since its opening to the public some four months or so ago. The steamboat R. L. Cobb was likewise fitted with four lamps and a head-light by this company.

Notwithstanding the lower bid of the Brush company, the city contract mentioned in my last letter has been closed and signed with the Louisiana company and the matter settled. One of the reasons given by the Mayor for signing the bill, was that it would encourage competition—but the Brush people call such measures, "*dis*-couraging competition." The Louisiana company is going right ahead with the work, as per contract—60 days is the time allowed in which to have everything in readiness. The New York Safety Steam Power Co. will not furnish the motive power for this plant, as it would not agree to the terms of the company. The Bass Iron Foundry of Fort Wayne will put up five 75 h. p. engines and boilers complete, and the Jenney company furnish ten dynamos of 30 lamps capacity each. In selecting their site, the Louisiana company has obtained ample space for any ordinary increase in business which will necessitate the enlargement of the plant. As yet the city fathers have not agreed among themselves as to the number and location of the towers and poles.

The Brush company has just offered to extend its field of usefulness by putting up 15 lamps on arms upon a street hitherto lighted by gas. This it offers to do for the sum of $180 per month.

Lighting companies in general had better keep their eyes open next month (May), as a city ordinance is being prepared which provides that the Mayor shall advertise for bids for lighting the city with gas or electricity for a period of years from January 1, 1886. Bids are to be received in May, and the contract awarded the 1st of June, thus giving the successful company ample time to have everything ready for a trial of the lights December 1st. All details necessary regarding the quality of the

Digitized by Google

lights and the ground to be covered will be inserted in the advertisement, and the same sent to all lighting companies in the country.

Since my last writing, the lines of the Baltimore & Ohio Telegraph Co. have reached the city, and an office opened for business. Starting with rates greatly lower than those of the Western Union, the company has been favorably received, and as much business has been presented as could be expected. Call-boxes will be placed throughout the heart of the city, and patrons furnished with messengers to receive their despatches. This company claims to be the first to introduce any opposition to the Western Union in the state of Texas, where it has already established many offices. It will also extend its lines largely during the summer in the Southern and Eastern states. In this city the business of the company is in the hands of Mr. E. Leloup, superintendent, and Mr. Robt. Ewing, chief operator. Rates of the Western Union have been reduced to all competing points to the same figures as those of the B. & O.

The Crescent City Telephone Co. put up its three hundredth pole yesterday and still the work goes bravely on. The $5 pole tax, I am told, it pays as it goes along, without any kicking. Mr. T. J. Perrin is at work putting up one of his multiple switchboards in the exchange, which he expects to complete and have ready for business before May 1. Some 70 instruments are already out, but only in the offices of some of the stockholders and their friends. A hundred of the improved instruments, working with a battery instead of a magneto-call, are ready and will be put out at once. Charges have not yet been decided on, but it is asserted that they will be greatly lower than the present Bell rates. In fact, the Crescent City admit there is room for but one company in this city, and if it can furnish a better service at less cost than has heretofore been enjoyed, it will take from the Great Southern all its subscribers,—if it can not do this, it will have to pull up stakes itself. A case of the "survival of the fittest" it appears to be, and time alone will determine the identity of that same.

New Orleans, April 16, 1885.

SAN FRANCISCO.

Electric Motor Agents on the Ground.—Arizona Taking the Lead in Business.—The Baltimore and Ohio Looking Over the Ground.—District Telegraph Competition Detrimental.—Rumored Salary Reduction.

The arrival in this city of several agents of electric motors applicable to railway purposes, should be convincing proof that your columns have directed attention to the favorable opportunity awaiting their introduction in this city. I wonder if the successful competitor will remember your journal in consideration of the "pointer" contained in my February letter.

Nevada is practically dead, and it would require "the last trump" to awaken it to its former activity; but Arizona is beginning to loom up, and promises to supersede Nevada in mineral wealth. So far Arizona has 50 telephone exchanges and 43 electric lights. This includes the territorial prison at Yuma which has three mast lights, and the agents are sanguine of doubling this number in a few months. San Diego, California, is agitating the subject of having that town lighted by the mast system of electric lighting, the same as is so successfully and satisfactorily operated in Los Angeles. Within the last two years the growth of southern California has been remarkably great, and the business which Sacramento and Marysville had a monopoly of, formerly, is now directed southward, which promises to be a better field. In the towns of Los Angeles, San Bernardino, Santa Barbara and San Diego there are in operation 375 telephones and 300 electric lights, this is indeed a good showing and much more encouraging than twice as many in older cities.

R. R. Haines is the pioneer telegraphist of southern California and Arizona; he is now manager for the Western Union at Los Angeles, where he also edits a temperance journal, of which cause he is a great advocate, hence you will observe R. R. does not stand for "Rum, Romanism." Uncle Rufus, as we call the venerable patriarch, was once an editor in the historic region of Cape Cod, Mass. To Mr. J. C. Sherer, also, much is due for the success and introduction of electricity in its various forms in southern California, and it must be indeed picturesque to pick oranges from the branches under the glare of electric lights.

Mr. James Gamble is busy. He has great speculations in his eye, and to some in his confidence he intimates that he will have all the towns from Seattle on the Sound, to San Diego in the south, connected with San Francisco before the people will realize that it can be done.

S. Spencer, vice president of the Baltimore and Ohio Railroad Co. is doing our state in a special car with some friends. It is reported that he has had several meetings with Mr. Gamble, and that arrangements will soon be consummated for the extension of the B. & O. telegraph to this coast. The lines of that company are already operated to Fort Worth in Texas, which is only about 1,200 miles from the southern boundary of California. A through line by the southern route would be much more reliable in the winter season, not being liable to interruption from snow and sleet, besides which it would secure the Arizona business, which is much better now than that of Nevada and Utah by the old route.

Mr. Spencer visited the Western Union office a few days ago to send some messages, and he signed them in his official capacity "Vice-pres't Balto. & Ohio R. R. Co." The receiver thought of course he held a frank, and asked him to show it, instead of which he handed out a gold piece which elicited the remark from the veteran receiver, "Well, you are the first vice-president of a railway that has paid me for a message in a long time." Mr. Spencer was evidently pleased and said, "we may have a rival line of our own here yet, and then I may satisfy you with D. H's."

The District rivalry still goes on. Mr. Gill, of the San Francisco company says he has the American District literally "knocked out," whilst the manager of the latter says its only a question of a few weeks before the San Francisco company will be compelled to sell out. To a man up a tree, however, it would appear that there is a good deal of buncombe and unnecessary expense resorted to. Honest rivalry is commendable. Quick, intelligent service is what the public wants and is willing to pay for.

I have seen the District system in '75 and '76, when there was no competition, give better service and more satisfaction at a much less cost, although the boys were then paid double what they are now. The same can be done again by both companies and with much more profit. The money expended by solicitors drumming up patronage, had better be distributed among deserving boys, who when encouraged are more efficacious drummers by their good work than all the loud talkers from Cape Cod to Goat Island.

The air is murky with rumors of reduction of salaries, to take place after to-day. As yet we have received no official notice thereof, and it is time enough to "Bid the devil good morrow when we meet him" than to go out of our way to do so. If it will result in weeding the force of its best men, the same as the increased hours has done in Ogden, Utah, it is to be hoped it will not become a law. It is "catch as catch can" in Ogden, anything that can telegraph is put down to the overland wires, and as a result that business is mercilessly butchered, and when a "respectfully referred" in due course arrives, the good man who has grown grey on that circuit is made to pay for it and Mr. Plug is allowed to escape the penalty.

This looks like a premium on incompetency. With the exception of those who are anchored by family ties, a good man will not be found in Ogden ere long.

San Francisco, Cal., March 31, 1885.

WASHINGTON.

The Senate Committee Favors the Electric Light.—The United States Electric Light Co. Outgrows Its Quarters.—An Electric Light Superintendent Selling the Company's Property.—The Patent Office Changes.—Completion of the Baltimore & Ohio Building.

The report of the Senate committee on public buildings and grounds, which, it was expected, would be made before the adjournment of the 48th Congress, so that an appropriation could be made to carry out the plan recommended during the then approaching recess, was not made until just before the close of the executive session. At that time no money, save from the Senate contingent fund, could be appropriated, the House not being in session. The committee starts out with the plump declaration that the electric process "is a safer, cheaper and more salutary light than any of artificial production, avoiding the heat and vitiated air resulting from the use of gas, to which is to be ascribed, in some measure, it is believed, the impure atmosphere of the chamber; but, out of abundant caution, the committee advise that further experience with and opportunity be allowed to observe the performances of this light before the substitution shall be made." It will be observed that the committee adopt the popular idea of "the impure air of the chamber," when, as a matter of fact, every sanitary engineer or chemist who has investigated the subject has pronounced it exceptionally pure, save in the corridors and cloak rooms. The air is carried entirely outside the building after coming in contact with the gas-lights which light the chamber, without a possibility of its return to the floor or galleries.

The estimated cost of the plant for lighting by the Edison incandescent system is given in round numbers at $15,000. The cost of continuously running 800 lamps, including interest on the plant, is put at 0.35 cents per lamp per hour, and an equal number of gas-lights at 0.9 cents per hour. Taking into consideration the irregular times at which the lights are required for the Senate, the estimate of cost is considerably advanced, and after a series of computations the estimate is reached of 0.88 cents per light per hour for the Edison, 16 c. p. lamp, and 01.15 per hour for a gaslight of equal brilliancy.

The committee, under the circumstances of the case, have authorized the superintending architect of the capitol, with the advice and approval of its chairman, to make such further

Digitized by Google

arrangements as may be desirable for continuing the test of this light by the Edison or other like system at reasonable and proper cost.

The United States Electric Light Co. has run itself up to the capacity of its original plant. The maximum of power and space has been reached, and at a meeting of the stockholders on Monday the directors were authorized to find a suitable location, and establish a new station of much greater capacity than the present one, and sufficient to meet any reasonably prospective demand in the near future. A variety of questions were left to the determination of the board, such as whether the funds for the extension should be raised by new stock or first mortgage bonds, and certain negotiations with the district authorities for concessions as to the running of wires, etc. Conclusions have not yet been reached by the board.

The Brush-Swan company seems to be doing but little in the way of practical work. Its late superintendent, B. M. Reed, however, appears to have done a thriving business for a while on his own account. Being left in charge of the company's warehouse, he negotiated with an Alexandria house for the sale of several hundred dollars' worth of copper wire. There was some difference about the price, but Reed finally wrote them that "the company accepted their offer," and delivered the wire in open day. He then reported that the wire had been stolen, and entered heartily into the efforts that were made to discover the thief and regain possession of the wire, even visiting Baltimore (at the company's expense) to trace up a clew that he claimed to have. Other detectives were more successful, and the wire was found in Alexandria. Reed, on being arrested, confessed his little scheme, and was held for trial. He hails, I believe, from some place in Ohio

The selection of Mr. Montgomery to fill the position of Commissioner of Patents, is regarded as one of the best of President Cleveland's many good selections. It is understood to be a personal selection made from a thorough knowledge of Mr. Montgomery's adaptability for the place, acquired as a member of the Buffalo law firm, and to have been heartily approved by President Cleveland's associates in that firm.

Gen. Vance, made assistant commissioner, was a strongly backed aspirant for the first place. He is a man of the strictest integrity and untiring industry. His fault if any would be that he strove too completely to master the details of everything coming before him for action. Major Dyrenforth, late assistant commissioner, and who was also endorsed by men of both parties, including it is said "Senator" Lamar, and whose displacement was made necessary for the appointment of Mr. Vance, goes out of office with many warm friends and many bitter enemies. He proposes to practice in this city as a patent attorney.

The subject of a postal telegraph has probably not been thought of as an administration measure, and if anything is done in that direction during the next four years the action will have its inception in one or the other branches of Congress The rates have been so reduced by ruinous competition, that for the government to enter the field now would leave it with a large balance on the wrong side of the ledger at the close of the fiscal year.

The Baltimore and Ohio company has gone one step further in cutting rates, and now is selling books of stamps with a face value of $11.20 for ten dollars. Carrying the idea on to a logical conclusion one of their larger customers sought to buy eleven books for an even hundred dollars. The offer was forwarded to headquarters, and a reply is awaited.

After encountering numerous obstacles and delays, this company has finally seen the completion of its new railroad and telegraph office building which is pronounced one of the most convenient and elegant structures of its character in the country. It is located on the site for so many years occupied by the Western Union company, corner Pennsylvania avenue and Fourteenth st., the best and most central point for telegraph business in Washington.

WASHINGTON, April 23, 1885.

ELECTRICAL NEWS AND NOTES.

THE PRINTING TELEGRAPH SUIT DECISION OF THE COURT.

In the Circuit Court of the United States for the Southern District of New York, the following decision was rendered on April 1, 1885, in the action of the Gold and Stock Telegraph Co. *vs.* the Commercial Telegram Co. *et al.*

SHIPMAN, *J.*:

This is a bill in equity to restrain the defendants from the infringement of reissued letters patent No. 3,810, granted to the plaintiff, as assignee of Edward A. Calahan, January 25, 1870, for an improvement in telegraphic printing instruments for registering the prices of gold and stocks. The original patent was dated April 21, 1868.

Upon the trial of the case, infringement of the second claim only of the reissue was alleged. The claim is in these words:

> Two or more type-wheels moving independently and controlled by magnetism, and arranged so as to print jointly or separately upon one strip of paper in two or more lines, substantially as specified.

To understand and construe the claim which is in controversy, it is important to know the state of the art at the date of the invention. In this case, the defendants took no testimony and therefore the history of the art, so far as it relates to this claim, is to be learned from the reference which was made to it in the cross examination and subsequent examination of the plaintiff's expert. The Theiler, French, and the Johnson, English patent for the Theiler invention, which seems to be conceded to have embodied the state of the art at the time of the Calahan invention, are not in evidence, but a general statement, and one which will be sufficient, can be given of the extent of the evidence which Calahan made.

Theiler had a two-wheel instrument, the wheels being moved by one electro-magnet and being geared together and necessarily rotating together. Letters were placed upon one wheel and figures were placed upon the other, and the letters were printed upon one line and the figures were printed upon another line of the same tape by depressing the corresponding type-wheel. But it was necessary to have complicated mechanism so as to prevent impressions from one wheel when the other alone was being printed from.

Calahan printed letters in one line and figures in another line of a tape, by the aid of two type-wheels, one of which could be rotated to the exclusion of the other, and a single press pad. His wheels moved or rotated independently of each other, while in the Theiler machine, one wheel could not be moved without rotating the other.

He says, in his specification, that his invention was intended, among other things, to dispense with the complicated mechanism theretofore made use of to cause an impression to be made when the type-wheel had been brought to a proper position, and describes his device as follows:

> A magnet and armature are employed in effecting the movement of the type-wheel, so that the same is turned to the required position, and then by an independent motion, separately controlled from that of the type-wheel, the impression is made, so that the type-wheel can remain after it is adjusted or be again moved previous to the impression being made. The impression is made on a strip of paper by two type wheels, so that the printing is in two lines, and the figures and fractions for denoting the prices or quotations are contained upon a wheel and combined therewith. Letters are provided for printing on the same strip of paper to denote the article to which the quotations relate. As the different machines will generally be but a short distance apart, it is preferred to make use of two or more wires communicating through the entire circuit of machines. One of these wires transmits the pulsations of electricity that act upon a magnet and adjust the type-wheel to the proper letter or number. The other wire transmits the pulsations of electricity, which, acting in a magnet, produce the impression upon the paper. In the drawings, three circuit wires are represented, one for the alphabet wheel, another for the number or figure-wheel, and the third for giving the impression; but the number of wires employed is unlimited. * * * * *. The two type-wheels, *k* and *l*, although on separate shafts, stand contiguous to each other, so as to be impressed separately or jointly upon the same strip of paper that is fed along beneath them, the impression from the respective wheels forming two different lines of printing. * * * *. Each of the wheels, *l* and *k*, has a blank space that is turned toward the paper while the other wheel only is being printed from.

This blank space prevents the wheel which, for the time being, it is not desired to print from, from making impressions on the paper.

The independent rotation of the type-wheels, as distinguished from type-wheels which must continuously and necessarily rotate together, is the principal feature of the invention of the second claim, and it is not a prerequisite to this independence of rotation that each wheel should be under the control of its own independent magnet. This is a feature of the Calahan machine, but it is not a part of the second claim.

The claim requires that each type-wheel shall move or rotate by magnetic action, independently of the other and that it shall not be necessary to the movement of one that the other should, at the same time, be rotated also, and that a strip of paper and one impression pad shall be moved up against the type-wheels by a magnet, so that impressions from the character upon either or both wheels may be made upon the strip of paper and thus a message may be printed exclusively from one wheel or may be printed in two lines from the characters on both wheels, that is, by the united or joint action of both wheels, but it is not a requisite that this printing shall be done simultaneously.

The great contest in this case was in regard to the meaning of the word "jointly," the defendants insisting that it meant simultaneously, and the plaintiff insisting that it meant, by united action, or acting in co-operation, and thus, that when there was occasion to use both letters and figures upon a single strip, as is usually the case in transmitting stock quotations, such printing could be done in two lines by the united or joint action of the two wheels.

The latter is, in my opinion, the correct interpretation of the claim for three reasons:

1st. The improvement or the advance in the art did not in fact consist in simultaneous printing. It did not remedy the existing evil and was not the thing which the patentee apparently wanted to accomplish.

2d. The patent does not mention simultaneous printing as a thing which the instrument was necessarily to do; it points out that the wheels were so arranged with reference to each other

Digitized by Google

that they could be used on one strip of paper jointly or separately, that is, either or both could be used to make one message, and when both were used, the impression from the respective wheels formed different lines. The idea which the specification and the claim convey, is that the operator can use both wheels and so a double-line message can be produced by their joint action, but there was no requirement that they must be used simultaneously.

3d. While the Calahan instrument, before a unison device was added to it, had the capacity of simultaneous printing, such printing is not and was not supposed to be of practical value.

The defendants', or the Field instrument, has two wheels, one, a figure wheel, and the other a letter wheel, on separate shafts both controlled by magnetism and each moving independently. The wheels print by their united action in two lines upon one strip of paper moved up by a press-pad, and can print by the use of either wheel separately. As in the Calahan machine, both wheels are provided with a blank space which is turned towards the paper while the other wheel is being used to print from.

The difference between the machine of the Calahan patent and the Field machine is that the latter has a device by which, after a wheel has ceased to print, it returns automatically to the zero point and is locked there before the other wheel can be rotated. In the opinion of the defendants, their machine is relieved from the charge of infringement, because the wheels do not move independently and cannot print simultaneously. The latter suggestion is disposed of by the conclusion that the claim does not require such printing. The defendants say that their wheels do not move independently, because it is a "condition of the rotation of one wheel that the other shall first be brought to a state of rest." This does not prevent independence of motion in the sense in which Calahan used the term independent. One wheel is not linked to the other, so that both must rotate together, which is what he desired to avoid. Either wheel is rotated without thereby rotating or moving the other, a result which he desired to gain.

So far as is disclosed by the record, the allegation of infringement is sustained.

The next point is in regard to the duration of the Calahan patent, the defendants insisting that no injunction can issue, because the patent expired on March 16, 1885.

William Edward Newton received, upon a communication from Elisha W. Andrews and Edward A. Calahan, an English patent for the Calahan invention, which was sealed on August 21, 1868, and dated March 16, 1868, the day on which the provisional specification, with the petition of Newton, was filed at the office of the Commissioner of Patents. The original United States patent to Calahan was dated April 21, 1868, and from the copy of the original patent, which is in evidence, it appears that the application must have been made as early as December 28, 1867.

The effect of the 16th section of the act of March 2, 1861, taken in connection with § 6 of the Act of March 3, 1839, upon the duration of the United States patents for an invention which had been previously patented abroad, has been frequently discussed. (*De Florez* v. *Reynolds*, 17 Blatch., C. C. R., 436.) But I am not aware that it has been supposed that the 6th section of the act of 1839 related to patents which were issued by the United States before an English patent had been sealed and published. In this case the English patent was sealed five months after the patent in suit was issued, and although the English patent was, when published, dated March 16, 1868, I do not suppose that such date has an effect upon the life of the subsequently issued United States patent.

It will also be noticed that the application for the United States patent was made before the provisional specification was filed in the office of the English Commissioner of Patents. The decision of Judges Grier and Kane in *French* v. *Rogers*, 1 Fish., 133, in 1851, was to the effect that a United States patent issued after the issue of the English patent, but applied for before the date of the application for the English patent, was not within the 6th section of the act of 1839. This point was left undecided by the Supreme Court in *O'Reilly* v. *Morse*, 15 How , 62, decided in 1853.

The second claim of the original Calahan patent was as follows:

> Two or more type wheels separately controlled by magnetism, and arranged side by side, or with their axis on the same line, so as to be impressed jointly or separately on one strip of paper, substantially as and for the purposes set forth.

The second claim of the reissue does not enlarge the original claim: it is a more exact and more clearly defined statement of the invention than the original patent contained, but the original claim would probably have received the same construction.

There should be a decree for an injunction and an accounting. The terms of the decree will be settled upon hearing.

THE DECREE.

At a stated term of the Circuit Court of the United States, in and for the Southern District of New York, held in New York on the 6th of April, 1885, Judge Shipman issued the following decree:

This cause came on to be heard at the February Term, 1885, of said court, and was argued by counsel for the respective parties, and thereupon, and upon consideration thereof, it is found and hereby ordered, adjudged and decreed, that the reissued letters patent, upon which this suit is brought, to wit, letters patent granted to the Gold and Stock Telegraph Co. as assignee of E. A. Calahan, dated January 25, 1870, and numbered No. 3,810, are good and valid in law. That the said E. A. Calahan was the original and first inventor of the invention described in said reissued letters patent No. 3,810; that the title thereto, and to the invention described and claimed therein, is vested in the complainant, and that the defendants have infringed the second claim of said reissued letters patent No. 3,810, and the exclusive rights of the complainant under the same.

And it is further ordered, adjudged and decreed that the complainant do recover from the defendants the profits, gains and advantages which the said defendants have received or made, or which have arisen or accrued to them by reason of any infringement by said defendants of the said second claim of said reissued letters patent No. 3,810, since the date thereof, as also the damages which the complainant have sustained by reason of said infringement, to be assessed as provided by statute.

And it is further ordered, adjudged and decreed that the said complainant do recover of the defendant their costs and charges and disbursements in this suit to be taxed.

And it is further ordered, adjudged and decreed that it be referred to John A. Shields, Esq., a master of this court (there being special reasons for his appointment, the same being the agreement of the respective counsel thereto combined with his experience in accounting in patent causes), to ascertain and take, and state and report to the court an account of the gains, profits and advantages which the said defendants have received, or which have arisen or accrued to them by reason of any infringement by them of the said reissued letters patent by making, using or selling the same since the date of said letters patent, and also to assess the damages suffered by the complainants herein by reason of any infringement by defendants since the date thereof.

And it is further ordered, adjudged and decreed that the complainant on such accounting have the right to cause an examination of the said defendants *ore tenus* or otherwise, and also the production of the books, vouchers and documents of said defendant, and that the said defendants attend for such purpose before said master, from time to time, as said master shall direct.

And it is also further ordered, adjudged and decreed that a perpetual injunction be forthwith issued in this suit against the said defendants, according to the prayer of said bill, said injunction to take effect on Saturday, April 11, A. D. 1885, at ten o'clock in the forenoon, and that public notice to the users of the defendant's instruments of the said injunction shall be given by the United States Marshal for this district, by inserting or causing to be inserted over his official signature in the New York daily *Herald* and New York daily *Times*, on April 8, 1885, a brief announcement of the fact of such injunction and of the time when it will take effect.

All questions in regard to treble damages to be reserved until the coming in of the master's report.

THE ELECTRIC RAILWAY INTERFERENCE.—DECISION OF THE ACTING COMMISSIONER OF PATENTS.

SIEMENS *vs.* FIELD.

Decided March 27, 1885.

ELECTRO-MAGNETIC RAILROADING.

APPEAL from the Examiners-in-Chief.

Application of Ernest W. Siemens, filed May 12, 1880.

Application of Stephen D. Field, filed March 10, 1880.

Mr. C. S. Whitman, for Siemens.

Mr. F. L. Pope and *Mr. F. W. Whitridge*, for Field.

In the appeal from the decision of the Board of Examiners-in-Chief, there are seven assignments of error, which I will consider *seriatim*.

First, error "in deciding that the caveat of Field shows substantially all that is shown in the issue presented." The two issues referred to arose in applications relating to a system of electro-magnetic railroading in which both the claims cover a combination composed of five elements. Of these elements four in each issue are similar, namely, a stationary dynamo-electric generator, conductors formed wholly or partly of the rails, a wheeled vehicle running on the rails, and an electro-dynamic motor on the vehicle; in the first issue the electrical connection between the generator and the motor is maintained by the wheels of the vehicle, with or without rollers, springs or brushes; and in the second issue, the two poles of the motor are connected with the generator through the two lines of conductors. In the caveat in question are mentioned plainly the generator, the motor, the vehicle, the wheels on one side of the vehicle insulated from their axles, and a supplemental conductor attached to the rails, all of which are to be used "to propel cars along tracks by means of electricity." The invention is not herein set forth in all its de-

Digitized by Google

tails, for that is not the office of a caveat; but there are, undoubtedly, contained in it the germs of the invention, as it subsequently took shape in the claims which induced these issues. The object of this caveat was to protect the inventor while perfecting his invention, and, read in the light of his subsequent specification and claims and in the light of the testimony showing the purpose and course of his experiments—as it must be read where doubt exists in regard to the full force of general and confessedly imperfect description—obscurity disappears, and the completed invention stands revealed, though still in embryo.

I, therefore, concur in the opinion of the Board upon this question.

Second, error "in refusing to hold that the conduct of Field, in failing to claim the invention for over two years after he knew of the public use by Siemens, constituted negligence." I find no warrant in the record for the implication herein that Field knew, at any time prior to filing the claims involved in these issues, that Siemens had used the identical combination covered by him. It is true that detailed descriptions of the Siemens electric railway in Berlin, appeared in the public prints in Germany, in July, 1879, but it does not appear that knowledge of them was brought home to Field. It does appear that he read a general description of the railway in the summer of 1879, and talked to various persons about it, but that is all. At that time his caveat was in the office, having been filed May 21, 1879, and, therefore, he was not bound to make claim until the expiration of the year. On March 2, 1880, he renewed his caveat, and on May 10, following, filed his specifications and claims. These specifications described the inventions involved in these issues, though the claims did not cover them, and on May 21, 1881, the claims were accordingly amended. That this amendment was made at the suggestion of this office, it is true; but that suggestion was made because the specifications unmistakably showed and described the combinations in question as part of the invention, and it cannot be denied that the patent law was designed to protect that invention fully. Certainly Field cannot be held to be guilty of negligence prior to March 10, 1880. Subsequent to said date his application was in the hands of this office, undergoing examination preparatory to issue of patent; and, since his specification exhibited these combinations, if patent had issued in July, 1881, without these claims, the courts would have sustained a reissue made on immediate application. If so, I see no room for a charge of negligence between March, 1880, and July, 1881. Hence the allegation of negligence falls to the ground, and the Examiners-in-Chief were right in not finding it.

Third, error "in holding that July 9, 1879, is the earliest date assigned to Siemens as an inventor." Said holding was based on the fact that on July 9, 1879, there appeared in a periodical in Germany, the first complete published description of the Siemens electric railway; and on the rule of this office that a foreign inventor will not be allowed to show a date of invention prior to the date of such a publication. The fact is not disputed, but the contention is that the rule is wrong. Into a discussion of the question I will not enter. It has been the settled rule of the Patent Office since 1846, at least (Tucker *vs.* Davis, II O. G., 224), has had the sanction of the Attorney-General (5 Ops., 18), and has been approved by the Secretary of the Interior (Rumpff *vs.* Kohler, C. D. 1883, p. 111). It is no longer an open question, and the rule should, therefore, be enforced so long as there is no judicial decision to the contrary. Counsel admit that it is "a question which has never been settled by the courts," and, therefore, in my judgment, the Examiners-in-Chief were justified in adhering to the established practice of the office.

Fourth, error "in considering testimony of Field which is inconsistent with the preliminary statement." The facts alleged are that the preliminary statement showed disclosure of the invention on May 10, 1879, and it is urged that "all testimony concerning communications to others (recited below) made prior to May 10, 1879, must be stricken from the record," citing Hopkins *vs.* Le Roy (C. D., 1880, p. 188). Said case decides that a preliminary statement may not be amended after the adverse party has disclosed his case by taking testimony, and is not authority for the above contention. Rule of Practice 105 provides that "the parties (to the interference) will be strictly held in their proofs to the dates set up in their statements." The language of the rule generally admits of but one interpretation, namely, that parties may prove the alleged dates, but no others; and, taken in connection with the object of the provision, as sufficiently disclosed in the case of Hopkins *vs.* Le Roy, it is to be understood as declaring that they shall not prove earlier dates, for the purpose of showing the conception, disclosure or completion of their invention prior to the dates assigned in their preliminary statements. The rule, as thus construed, is amply strict and sufficiently protective of the parties. To extend it to a rejection of all testimony showing an earlier date would be, in view of the infirmity of memory in parties and their witnesses, a hardship, and, in view of the fact that the purpose of the interference is to ascertain priority as claimed, a denial of justice. The only word in the rule of doubtful import is "proofs," and, in my judgment, it should be construed as admitting, as proofs of the date fixed upon, evidence showing the fact alleged on any prior date. To admit such testimony, for such a purpose, is consonant to sound reason, is not oppressive, and is calculated to promote the objects of interference proceedings. If the Examiners-in-Chief considered Field's record showing communications to Ladd in 1870, 1878, and in February, 1879, and to Milliken in 1877, 1878, and in May, 1879, it is evident that they did not find from it the date as earlier than May 10, 1879; and so far as the Examiner of Interferences considered this testimony, it is plain that he restricted it to proof of the date last mentioned. In this view of the case there was no error in the action of either tribunal

Fifth, error "in refusing to consider the drawings of Siemens made in 1878." This falls under the third assignment of error, and the action of the Examiners-in-Chief is deemed proper for the reasons above stated.

Sixth, error "in awarding priority to Field, as his claims, which have been involved in interference, relate to matter which is not described in his specification or shown in his drawings." This question is *res judicata* between the parties. In overruling a motion to suspend the interference and refer the case to the Primary Examiner, Mr. Commissioner Butterworth held on February 9, 1885, that "Field's drawing and specification also appear clearly enough to illustrate and describe the construction involved in the two counts of the issue now objected to." Wherefore, the Examiners-in-Chief properly declined to re-open the question.

Seventh, error "in awarding priority of invention to Field, for that the testimony of Siemens establishes that he (Siemens) was first to discover the dynamo-electric principle of transforming work into current and current into work; first to publish the discovery to the world; first to describe to others the application of this principle to an electric railway; first to make drawings from which a practical railway could be constructed; first to construct and use a practical electrical railway; first to introduce the electric railway into commercial use, and first to apply for a patent." The first two of these reasons seem to be urged in bar of patents for all inventions by others than to Siemens based on a dynamo-electric machine in combination, and is too widely removed from the law and the decisions of the courts to warrant discussion. The next four reasons have been dealt with under the second assignment of error, and require no further elucidation. The last reason is founded on a mistake of fact, for the record shows that Field's application for patent antedates that of Siemens by more than two months.

The foregoing are all the points raised by the appeal, but in argument, counsel for Siemens has alleged the following as a defect, namely, that Field has not filed the supplemental oath required by Rule of Practice 47. Said rule requires "a supplemental oath to the effect that the subject-matter of the proposed amendment was part of his invention, and was invented before he filed his original application," in cases where the applicant seeks by amendment "to introduce any claim not substantially embraced in the statement of invention or claim originally presented, and therefore not covered by the original oath." In this case the amendment was made at the suggestion of the office under the Rules of Practice then in force. The amendments introduced by Field were thus, in the judgment of the office, substantially embraced within the original statement of invention. Consequently, the case is not one where, under the practice, the supplemental oath is required. (C. D. *in re* Eaton *et al.*, iv., O. G., 525.)

For the foregoing reasons, the decision of the Examiners-in-Chief in awarding priority to Field is affirmed.

R. G. DYRENFORTH,
Acting Commissioner.

MARCH 27, 1885.

SUBTERRANEAN WIRES IN PRACTICE.

APPENDIX TO REPORT OF MASSACHUSETTS RAILROAD COMMISSIONERS (See page 115).

[A.]

Notes on the Subject of Underground and Overground Lines of Telegraph Located on Road and Railway for Commercial Working.

The objections to having a number of independent telegraph lines established on a railroad location are: the amount of space taken up by the wires, the interference with the sight of signals and the liability of broken poles causing accidents to trains.

The proper distance from track at which telegraph poles should be placed for railway working is the line of the right of way. For independent working it is the line of the nearest road.

The limit of the extent to which wires can be laid underground is simply a question of insulation, *i. e.*, an insulation which will not retard working, and at the same time prevent interference. Underground wires should be so insulated that no moisture should penetrate the outside covering: it should be reasonably decay-proof, water-proof and fire-proof; it should not carbonize or corrode the conductors. The insulation should be low but the conductors well separated and kept clear from all

Digitized by Google

atmospheric influences as well as from the earth. Underground wires are largely used in other countries. London has nearly a complete system, and in Germany there are 221 cities connected together; 3,400 miles in all of underground, containing 23,000 miles of wire. The cost of the German system was $2,639 per mile of 21 wires, placed in pipe and buried at a depth of four feet. This includes labor, material, etc., all ready for use.

Sectional boxes can be laid for $2,000 per mile, sufficient to accommodate several hundred wires.

Brooks' cable system laid through pipe filled with oil, containing from three to four hundred wires, can be placed at a cost not exceeding $20 per line per mile ready for operation.

The objections to the underground are: the liabilityof causing retardation, causing slow transmission of messages, and the trouble and expense in making repairs.

An eminent English authority on the subject of telegraph lines notes: Where there is a choice between an overground and underground system there should be no hesitancy in selecting the former, for not only is the first cost less, but faults occurring upon them can be more readily traced and rectified; but that where there is a choice of location for an overground independent line of telegraph between a road and railway, they both offer advantages and it is no easy matter to say which is to be preferred.

The first cost of a line located on a road is greater than upon a railway, but yet its subsequent maintenance under certain conditions is less; the supervision of it is more perfect, for the fact that the poles are erected along the side induces better inspection and little imperfections are thus easily detected.

On a railway location walking is difficult and consequently too often neglected, the lineman contenting himself with traveling by train, from which close inspection is next to impossible.

The reparation of faults is as a general rule more speedily carried out upon roads than upon railways. In case of the former, the lineman can start immediately the fault is reported to him: with the latter he has not only too often to wait some time for the starting of a train, but frequently is carried past the fault and has to return to it many miles on foot.

For an underground system carrying wires between cities, *i.e.*, outside of street limits, following a railroad or turnpike, a conduit alone can be laid for $1,580 per mile, capable of holding 50 wires. The wires with good insulation will cost $105 a mile each, if separate; if by cable carrying 10 or 15 wires each, the cost would not exceed $85 per mile for each conductor.

Taking this as a basis, a system with provision for carrying 50 wires, with 15 laid in place, would cost, all complete, $2,855 per mile.

In cities, within street limits, the cost of labor to be added to the above depends on the location with respect to pavement or street, but in any case would not add more than $500 per mile to the above. Cross lines leading to houses are not included.

REPORT FROM MR. HAMILTON

As to Western Union underground wires in New York city (there being practically no other underground system), from general office to Pier 18, two parallel pipes of 2,031.50 feet.

4,063 ft. iron pipe, at 20c. per ft.	$812 60
Coating 130 pipes, 1,251 ft., at 3 cents	37 53
Carting	8 00
Laying (two 1,850 ft. parallel) 3,700 ft. of pipe, two pipes in trench, at 22½c	832 50
Setting and cutting 4 flush boxes (test boxes)	72 00
Laying and furnishing stone for 60 yards Belgian pavement, at $2.25	135 00
Elbows, iron work, etc., at cable house (Pier 18)	50 85
Extra labor, etc., at and around Pier 18	60 50
Cable house at Pier 18, N. R., invoice by G. M. P	160 25
	$2,169 23
Two cables of 2,130 ft. each, or 4,260 ft. (30 conductor cable)	$3,424 15
Labor of drawing in	40 91
	$5,634 29

In the latter part of 1876 or early in 1877, two 30 conductor cables (about 2,200 feet each) were laid from the General Office, 195 Broadway, to Pier 18, North River.

Eight or more conductors in one of these cables failed before the end of 1880. These were repaired about October, 1881, by drawing in a new piece in place of the defective portion.

Seventeen conductors in the other cable failed in November, 1880, by breakage of iron conduit under the dock. Overhead wires were substituted until April, 1881, when this cable was replaced by a new one containing 60 conductors.

At the present time three conductors are interrupted, 57 good.

The remaining 30 conductor cable was extended to Pier 16, in February 1882. It was afterwards replaced by another of 60 conductors.

At one time 20 conductors by this route were interrupted by the heat from the Steam Heating Company's pipes, but I am unable now to say whether it was the 30 conductor before its replacement, or the 60 conductor cable.

At the present time 4 conductors are interrupted, 56 good.

A 12 conductor cable, 2,200 feet long, was laid between the office, 195 Broadway, and 14 Broad street, in October, 1876; cable destroyed in October, 1883, by steam pipes.

Has not been replaced.

A 28 conductor cable, 2,050 feet long, was laid May, 1880, between 195 Broadway and 8 Broad street; 11 conductors failed November, 1882. Cause, steam pipes.

Eight conductors working now.

A 30 conductor cable, 500 feet long, was laid between 134 Pearl street and the Cotton Exchange, in May, 1882. At present time two conductors are defective, 28 good.

A 60 conductor cable, 2,778 feet long, was laid between 195 Broadway and 134 Pearl street, in May, 1882. Failed November, 1882. Cause, steam heating. Cable has been abandoned.

A 30 conductor cable, 730 feet long, was laid in Jersey City, December, 1876. Failed October, 1882. Cause, exhaust steam pipe passed underground near cable, melted gutta-percha.

Repaired soon after, and an additional cable put down. All conductors perfect at present time.

A 30 conductor Brooks cable was laid between Newark and Jersey City suburbs in 1880. The wires failed rapidly when put in service. This cable was afterwards repaired, part of the route changed, and considerable new cable added or substituted for defective portions in 1882. It saw scarcely a year's service, however, and none of the conductors are now in use. The experiments with this cable were made at an expense of more than $20,000.

GEO. A. HAMILTON,
Electrician.

MAY 27, 1884.

WHAT EDISON IS DOING.

I found Mr. Edison last week in his laboratory on Avenue B, and asked him what was the newest thought that he had harnessed to matter. "This" he answered, and called my attention to a board hanging by one edge to ropes above our heads, its surface covered with tinfoil. In further explanation he said, "That solves the question of telegraphing to running trains. As soon as that little device is adopted every moving train in the country will become a telegraphic station, and anybody aboard the train may be telegraphed to as easily as if it were standing still. This will not be done by putting up a new set of wires, under the train or at its side, but by using the ordinary telegraph now running by the side of the track. It is a new, and hitherto unknown process of induction, by which I make electricity jump thirty-five feet through the air, carrying the message without spilling it. How's that for lively."

The inventor's face glowed with pleasure at the thought as he went on: "By putting up this tinfoil covered board lengthwise on the top of each car I can catch a message from the wire strung on poles thirty-five feet off, and can fling an answer back to the wire. It requires no change in the wires of any sort. The secret of it is in the machine for transmitting. When I was investigating what I called the 'etheric force' a few years ago I accidentally discovered certain curious properties of static electricity. These I have now applied. The process is very inexpensive, as three men could equip a road 300 miles long for $1,000 in three or four days. It seems certain that its adoption will be general, so that every train will be run from headquarters and every passenger will be accessible to his friends. What do I call it? I haven't named the baby yet." Mr. Edison looked exceedingly well, although he was robed in a gown of bed-ticking reaching from collar to ankles which was not very picturesque.

At the Edison factory in Goerck street a new passenger car of the elevated road is being equipped with the electric motors which are to take the place of the present steam locomotive in the early summer. The car is turned bottom upward, and two dynamos weighing about 1,000 pounds each are adjusted to the under side in proximity to the wheels. One dynamo drives the four forward wheels, and the other the four rear wheels. Every car is to be similarly rigged so as to bear its own motive power. A train of four cars, instead of having one 16 ton locomotive, with two great driving-wheels, will have no locomotive, but every one of the 32 wheels will be a driving-wheel. The 8 dynamos will weigh about half as much as a locomotive, and they will all respond to the touch of one conductor. Mr. Bachelor, in charge of the work, tells me that one car can be run alone in the easy hours, while in the crowded hours ten or a dozen can be run in a train, and that they can reach a speed of 20 miles an hour in the first 300 feet after starting. Mr. Russell Sage, whom I saw yesterday, feels sure that the electric motors will enable the aerial roads to carry one-third to one-half more passengers than they are now doing, and that the trains will be much more safe and manageable.—W. A. CROFFUT, in *New York World.*

THE FAST-SENDING TOURNAMENT.

There were 12 contestants in the test of Morse transmission which took place at the rooms of the United Press, in this city, April 5th. The number of words selected for the competitive trial of skill was 500, composed of 2,368 characters, including punctuation. Both speed and excellence were considered in awarding the prizes. The respective time occupied in transmission was as follows:—J. W. Roloson, Stock Exchange, 10:32; Frank J. Kihm, United Press, 10:38; William Gibson, Stock

Digitized by Google

Exchange, 10:57; M. J. Doran, Bennett & Co., 11:26; John G. McCloskey, United Press, 11:44; W. L. Waugh, Stock Exchange, 11:57; Charles H. Davis, United Press, 12:01; William J. Curtis, United Press, 12:27; Walter L. Prentice, United Press, 12:49; R. J. Murphy, Western Union, 12:51; Robert W. Martin, United Press, 12:51; F. G. P. Griffith, United Press, 13:15.

J. W. McLaren, Manager of the Baltimore & Ohio's local office; D. B. Mitchell, chief operator of the Western Union in this city, and Walter P. Phillips, general manager of the United Press Association, acted as judges, and read the matter sent from a local wire in an adjoining room. The first prize was awarded to J. W. Roloson for great speed and remarkable clearness, considering the time made; second prize to William Gibson for unusual speed and pronounced excellence; third prize to Frank J. Kihm for remarkable speed, marred by faults in the formation of characters; fourth prize to William J. Curtis for absolute correctness, speed and beauty of style; fifth prize to F. G. P. Griffith for speed and excellent manipulation with the left hand. The contest was the third ever held in this city, and the time made beat previous records. The first match took place in 1881, when the best time, 11:10, was made by W. L. Waugh, who came out No. 6 in this contest. The second contest came off in August of last year, and the best three men were W. L. Waugh, 11:32; William Gibson second, and Frank J. Kihm third.

TROUBLES OF THE UNITED STATES TELEPHONE MANUFACTURING COMPANY.

The announcement is made that the United States Telephone Manufacturing Co. is in trouble. A judgment for $2,855,21 was obtained by James W. McDonough for money loaned to the company. Execution was issued on the judgment and returned unsatisfied, whereupon sequestration proceedings were instituted, and H. H. Eldred was appointed receiver on April 24th by Chief Justice Daly of the Court of Common Pleas.

This company was organized about five years ago with the design of entering into competition with the American Bell Telephone Co. A large number of patents were secured, some of which were believed to be of great importance, among others those of James W. McDonough, one of the competitors for the honor of having been the original inventor of the speaking telephone ; Geo. W. Coy and Charles E. Buell, who claimed to be the originators of the exchange system, and T. A. Connolly, the inventor of an automatic telephone exchange system. Legal proceedings were commenced against some of the local companies licensed under the Bell patents, alleging infringements of one or more of these patents, which however have never been brought to any conclusion. The expenses of litigations in the courts and of interference proceedings in the Patent Office have probably crippled the United States company, which has been without apparent resources, except the amounts realized from the sale of stock, which since the decision in the Drawbaugh and other cases in favor of the Bell company have probably been very small. The collapse of this company apparently leaves the American Bell company for the present without any antagonist of serious importance in the field.

THE PHELPS INDUCTION TELEGRAPH.

A special and very successful test of Lucius J. Phelps's system of communicating with moving trains was made on March 25th, for the information of members of the New York Electrical Society, who were invited to be present by the company controlling the patent.

On this occasion two sets of apparatus were in circuit on the train, one with an ordinary Morse sounder, the other embracing a receiving telephone, from which the signals could be distinctly read. One of the visiting operators, who had never seen the system in use, sent and received messages while the train was in motion. In order to show the wide margin of inductive influence, a further test was made, while the train was running on a parallel track, 11 feet from the main line, which was equally successful. The result was highly gratifying to all, especially in view of the failure at the previous exhibition on February 13, which is said to have been the only mishap of the kind during three months' trial.

MINIATURE INCANDESCENT LAMPS.

The use of electric incandescent lamps for many scientific and industrial purposes is creating quite an extensive market for lamps of various powers, operated by dynamos, primary and storage batteries. For surgical, dental and microscopical use there appears to be nothing so convenient and effective. Outfits of this character are now to be had thoroughly well made, and reliable in their operation.

Messrs. H. Guimaraes and Co. are devoting their attention to this field, and have perfected a pocket battery which is not only adapted for lighting on a small scale, but convenient for testing, and useful for various purposes.

Messrs. Stout, Meadowcroft and Co., are also engaged in supplying the demand which has arisen for miniature electric lamps, and have already brought out a variety of styles suitable for actual service. All who are interested in this novel branch of electric lighting, will certainly derive pleasure from examining these tiny isolated plants.

ELECTRIC LIGHT AND POWER.

Domestic.

The Electric Locomotive and Railway Supply Co., of New York city, has been incorporated for the purpose of manufacturing electric motors, etc. The incorporators are George W. Titcomb, William Ettinger, J. D. Gillett, Joseph Weis, Francis Weis, Wm. F. Drake, A. A. Drake, Elwood McNab and John Van Wagoner. The capital of the company is $1,000,000.

It is probable that the electric light will cut an important figure in connection with the franchises for lighting streets and dwellings in St. Louis.

The Thomson-Houston Electric Light and Power Co. has been organized at Quincy, Ill.; capital, $100,000; incorporators, William M. Berry, Samuel A. Blasland and Gerald M. Hill.

The Springfield, Ill., city council has passed an ordinance providing that railroad companies shall erect electric lights at all principal streets crossed by said roads. Considerable comment has been caused by this action, as the ordinance was pushed by parties interested in an electric lighting company.

The Jenney Electric Light Co., has been incorporated in Indiana. It is based on the inventions of Charles D. Jenney, heretofore identified with the Fort Wayne Jenney Electric Light Co., with which he has had a contract, made when he was 17 years of age. This agreement was recently rescinded upon his attaining his majority.

Since our last issue the United States Illuminating Co. has installed a plant of 900 Weston incandescent lights in the Washington Building, No. 1 Broadway, and have nearly completed a 150-light plant for the new Mortimer Building, No. 11 Wall street, and another of the same size for the meat house of J. Halstead and Co., on Forsyth street, all in New York city. A 300-light plant is now being fitted up in the building of the Brooklyn *Eagle.*

The Weston incandescent lamp seems to be in special favor for lighting steam vessels. The United States Illuminating Co. are fitting up two new boats just launched by the Grand Street Ferry Co. with 75 lights each.

The new skating rink recently opened at Greenville, N. J., by E. J. Reiss is splendidly illuminated by 12 large Weston incandescent lamps of 125 candle-power; the effect is greatly admired by visitors.

The United States Electric Light Co., have placed a 250-light incandescent plant in the Point Clear Hotel at Mobile, Alabama, and a 100-light plant in Coates and Potts woolen mill at Philadelphia.

We mentioned in a recent issue the fact that the New Montezuma Hotel at Los Vegas, N. M., was being fitted by the United States company with the Weston incandescent lights. Since then the plant has been completed and set in operation. It is worthy of mention that there is not one foot of gas pipe on the premises. This is probably the first hotel in the world lighted throughout every part exclusively by incandescent lamps.

The New York Electrical Society proposes, in place of one of its regular meetings, to spend an evening in visiting and inspecting the various stations of the United States Illuminating Co. in New York. Such an expedition will prove interesting and profitable to the members of the society, as the stations of this company are very complete, and well worthy of a careful inspection by all interested in the industrial application of electricity,

The Holyoke Electric Light and Power Co., of Holyoke, Mass., recently established a 105 arc light plant of the Schuyler system. The city has taken 50 lights for the streets and the remainder are taken by private parties. Both water and steam power for driving the dynamos is furnished by the Holyoke Water Power Co., in whose buildings the dynamos are placed.

In addition to the streets and parks of New York city already lighted by electricity, the United States Illuminating Co. are also to light Catharine street from Catharine square to the East river, Chambers street, from Broadway to the North river; Fulton street, from river to river, and Canal street, from the Bowery to the North river. A petition signed by down-town business men asking that the streets leading to the ferries might be lighted by electricity, cannot be complied with as the available surplus of $12,000 is not sufficient.

Foreign.

At Antwerp, Belgium, a large central station is being fitted up for supplying private houses with electric light. The first in-

Digitized by Google

stallation will be for 6,000 incandescent lamps; the dynamos employed in this case will be Gulchers, and the current will be conveyed by means of underground wires. according to Callender's system, placed in cast-iron pipes filled with non-conducting material. This installation, when completed, will be the largest of its kind in Belgium.

It has been decided that in the autumn of the present year several important public buildings of Vienna are to be tentatively lighted by electricity. Between the imperial court and the gas company an agreement has been concluded for the electric lighting of the imperial palace (Hofburg), as well as of two theatres, viz., Hofopern theatre and the new Burg theatre. The central station for the lighting of these buildings is to be established in the Porcellangesse, on the very spot on which, fifty years ago, the first gas works were built. This principal station is to be connected by means of underground wires with several other stations situated in different parts of the Austrian metropolis. There are some Turrettini accumulators, by means of which it will be possible to carry on the lighting of all these buildings without interruption. The Opera theatre will have 4,000 and the new Burg theatre 3,000 lamps; the new section of the imperial palace, and part of the old one, will have 5,000 lamps between them. The installation of the electric light in the Opera theatre and in the emperor's old palace is to be finished in the autumn of the present year; in the new Burg theatre and in the new section of the palace it is to be finished as soon as the buildings themselves are ready for it As regards the introduction of the electric light in the parliament house and the new university, the negotiations are still proceeding. The necessary funds for the above installations have been supplied by the gas company itself.

The Swan patents have become very valuable in Germany in consequence of a decision by the German courts against the two firms, Naglo Brothers and Eisenmann, for infringement of the Swan incandescent lamp patent. The judgment forbids henceforward the manufacture and sale of Swan lamps in the whole German empire in favor of the Edison company. This decision will have a considerable bearing on the development of electric lighting in Germany.

Messrs. Kitson & Co., engineers, Leeds, have had ordered two sets of electric lighting plant to assist in the work of constructing the Suakim line. Each of the two sets of plant will comprise a small locomotive boiler and a Parson's patent high-speed engine, with a six light Anglo-American Brush dynamo-electric machine, with all other accessories. This machinery will be fitted into a four-wheeled specially designed railway wagon, which will be run forward along the lines of the railway as its construction is proceeded with. From the dynamo machine cables will convey the electric current to six Brush lamps, which will be fixed on portable tripods 35 feet high, and placed along the side of the portion of the line under construction at distances of about 100 yards apart.

MANUFACTURING AND TRADE NOTES.

The Western Electric Co. have just completed at their works in Chicago, five miles of underground cable to be used for telephone purposes in Washington, D. C. They are now making additional switch-boards for Liverpool, England, Toronto, Ontario, and Kansas City, Mo., and are making a new one to go to Glasgow, Scotland. Recent orders are for an electric light machine with lamps to go to London, England, and a 40-light electric plant for Morgenthau, Borland and Co.'s store, in Chicago.

The California Wire Works, San Francisco, Cal., is one of the most important industries of the Pacific coast. The wire mills have a capacity of 5,000 tons per annum. The various departments embrace galvanizing and tinning works, machine shop, wire weaving, barbed wire factory, telegraph cables, etc. The works occupy nearly three acres of land.

The trustees of Pope, Cole and Co., of Baltimore, have made a proposition to pay 80 cents on the dollar of the $500,000 unsecured liabilities, of which $100,000 is to be paid in cash, and the remainder on time. The assets are large, and there is a probability a settlement will be made on that basis. Such a result will assure a continuance of the copper works, one of the most important industries of Baltimore.

PERSONAL MENTION.

Col. R. C. Clowry succeeds the late Gen. Anson Stager as president of the Central Union Telephone Co.

THE TELEGRAPH.

The employés of the Bankers and Merchants' Telegraph Co., at Buffalo, N. Y., stopped work on the morning of April 14th in order to enforce a settlement with the company. A compromise was effected next day.

A foreclosure suit for $3,000,000 has been brought against the American Rapid Telegraph Co. by the Boston Safe Deposit and Trust Co., in the United States Court at Hartford, Conn.

The Commercial Telegram Co. commenced an action in the New York Superior Court, on April 16, against the Gold and Stock Telegraph Co., claiming $50,000 damages for an alleged libel contained in a circular issued by the defendants with the object of persuading brokers and others throughout the city not to use the instruments of the Commercial Telegram Co.

THE TELEPHONE.

The committee of three appointed by Speaker Marsh, of the Ohio state legislature, to investigate the telephone companies doing business in Ohio, have prepared a report, in which they say:—"There are about 12,000 complete sets of instruments in use in the state, all owned and controlled by the American Bell Telephone Co., of Boston. These instruments are leased to the local companies at an annual rental of $20 for each set, making the annual tribute paid by these local companies over $200,000. The cost of each set of instruments did not exceed $3.35. On instruments which did not cost the Bell company over $40,000 the company receives over $200,000 annually. The Bell company, before granting a franchise to a local company, exacts from 30 to 35 per cent. of all stock of the local company using its instruments, and from 20 to 25 per cent. of the gross earnings of all toll or extra territorial lines." The committee states that, in its judgment, the Bell company is an imperious and unconscionable monopoly, and should be restricted by legislation, or at least be taxed upon the commercial value of its instruments; also, that the Bell company should be required to pay, in addition to the taxes upon its instruments, a tax upon gross receipts.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER *by* Pope & Edgecomb, *Solicitors of Patents for Electrical Inventions,* 11 *Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From March 24, to March 31, 1885 (inclusive).

Alarms and Signals:—*Signaling Apparatus*, F. B. Herzog, 314,292, March 24. *Method of Latent Signal Transmission*, same, 314,293. *Circuit Changer for*, same, 314,294. *Signaling Circuit*, T. D. Lockwood, 314,386. *Indicator*, F. J. Sprague, 314,891, March, 31.

Clocks:—*Secondary Clock*, W. F. Weisgerber, 314,634, March 31.

Conductors, Insulators, Supports and Systems:—*Conduit for Wires*, J. S. Dubois, 314,568, March 31; M. H. Dewey, 314,655; D. Brooks, Jr., 314,-791. *Copper Covered Wire*, J. Spruce, 314,618. *Holder for Lightning Rods*, S. R. Lawshe, 314,385, March 24.

Dynamo Machines and Motors:—*Armature for Dynamo*, C. L. Healey, 314,242, March 24.

Galvanic Batteries:—I. L. Roberts, 314,722, March 31.

Lamps and Appurtenances:—*Arc-Lamp*, C. M. Ball, 314,418, March 24; P. Diehl, 314,567, March 31. *Means for Suspending Lamps*, W. H. O'Beirne, 314,976.

Miscellaneous:—*Means for Generating Steam by Electricity*, W. W. Vaughn and E. D. Eldridge, 314,277, March 24. *Induction Coil*, F. E. Fisher, 314,816, March 31. *Apparatus for Measuring the Flow of Liquids*, W. A. M. Brown and John M. Porter, 314,914.

Protectors:—*Safety Catch*, E. H. Johnson, 314,582, March 31.

Railways and Appliances:—*Car Brake*, H S. Park, 314,709, March 31. *Railway Signal*, W. T. Waters, 314,760, 314,761, 314,762, 314,763.

Storage Batteries:—E. T. Starr, 314,892, March 31.

Telegraph:—*Register*, E. Estienne, 314,525, March 24.

Telephone Systems and Apparatus:—*Telephone*, F. Blake, 314,312, March 24; H. Alabaster, T. E. Gatehouse and H. R. Kempe, 314,304. *Circuit for Telephonic Communication*, H. Alabaster and T. E. Gatehouse, 314,305. *Receiver*, same, 314,306. *Mechanism for Operating Telephone Night Bells*, F. E. Fisher, 314,817, March 31. *Switch*, same, 314,818. *Talking Strap for Switch-boards*, same, 314,819. *Transmitter*, H. Alabaster and T. E. Gatehouse, 314,307, March 24; G. M. Hopkins, 314,841, March 31. *Adjustable Support for Telephone Receivers*, J. M. Fitch, 314,371, March 24. *Mechanical Telephone*, F. C. Ludlow, 314,946, March 31.

Expired Patents:—A list of the more important electrical patents which have expired since March 1, 1885, together with those which will expire during the current month, is subjoined:—A. H. Castle, *Insulator*, 75,365, March 10.—C. F. Varley, *Earth Wires for Telegraph Poles*, 75,492, March 10.—L. B. Firman, *Fire Alarm Signal Box*, 75,743, March 24.—S. S. Laws, *Dial Indicator for Reporting Quotations*, 75,775, March 24.—C. F. Varley, *Insulator*, 75,815, March 24.—J. L. Finn, *Combined Insulator and Lightning Arrester*, 75,889, March 24.—E. A. Calahan, *Dial Indicator for Reporting Quotations*, 76,157, March 23.—C. F. Varley, *Insulator*, 76,358, April 7.—W. I. Reid, *Electro-Magnetic Ship's Log*, 76,521, April 7.—C. G. Page, *Induction Coil Apparatus and Circuit-Breakers*, 76,654, April 14.—E. Gray, *Induction Relay*, 76,748, April 14.—C. F. Varley, *Process of Treating Insulators*, 76,960, April 21.—E. A. Wood, *Electric Steam Engine Governor*, 76,965, April 21.—E. A. Calahan, *Stock Printing Telegraph*, 76,993, April 21.—R. E. House, *Electro-Phonetic Telegraph*, 77,872, May 12.—C. Duraut, *Self-Adjusting Relay*, 78,076, May 19.—W. Perkins and G. G. Tandy, *Insulating Material for Electric Conductors*, 78,125, May 19.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

NEW YORK, JUNE, 1885.

INCANDESCENT LITIGATION.

ON Friday, October 4th, 1878, the electric light was discovered by Thomas A. Edison, of Menlo Park, New Jersey. There can be no doubt about the exact date, for the announcement was made to a reporter on the following day, and formed the particular sensation of the next issue of a prominent metropolitan journal. On Monday the news was telegraphed and published in London, where it at once precipitated a panic in gas securities, in which their total value fell off some millions of dollars. As to the personal identity of the discoverer, we find it certified to in connection with an illustrated article subsequently published in a leading monthly magazine, in which Mr. Edison, in his characteristic handwriting, over his unmistakable signature, modestly says that this is an authentic account of "*my* invention of *the* electric light."

For several months after the announcement of the discovery which was to revolutionize the illumination of the world, the details were carefully withheld from the public, while a syndicate of promoters and capitalists was being formed to exploit the invention. The plan of campaign determined upon was ingenious and unquestionably effective. There are certain metropolitan journals which, as the initiated well understand, may be persuaded, by appropriate arguments, to lend the use of their columns to those who know how to make good use of them. The statements, speculations and prophecies of the gifted inventor are served up to the public in the most appetizing form. They profess to have been derived from him during an "interview" with the reporter; this gives them a flavor of high authenticity, while, on the other hand, in case it becomes necessary to disavow any of the published statements, it is easily done on the ground that the inspired person must not be held responsible for the inaccurate or absurd statements put into his mouth by newspaper men. In this manner the country was flooded with the most extravagant assertions in relation to the alleged capabilities of the new electrical discoveries, all purporting to come directly from Mr. Edison. Thus, he is quoted as saying, on October 5th, 1878, that he had computed the relative cost of light, power and heat generated by his electrical system to be forty-six times (mark the accuracy) cheaper than that obtained in the ordinary way. The statement was made at the same time that the amount of light given by 1,000 cubic feet of gas could be obtained by the Edison system for 12 to 15 cents. On the strength of the continual reiteration of these and other equally preposterous statements, the shares in the Edison company quickly rose to an enormous premium. In February, 1879, the details of the great invention, having been duly patented in foreign countries, were published for the first time. The scientists of the world eagerly scanned the specifications, and then tried their best to look in each other's faces without laughing. The wonderful discovery consisted of the old, old device of a lamp comprising an incandescent platinum wire, a thermal regulator to keep it from becoming overheated, and what was not so old—an electric generator, formed of a gigantic tuning-fork, waved to-and-fro before the poles of an electro-magnet, whereby, in the words of the inventor, "a powerful electric current may be obtained by the expenditure of a small mechanical force," inasmuch as "it is well known that vibrating bodies, such as a tuning-fork or reed, can be kept in vibration by the exercise of but little power"! As the London *Engineer* remarked, this was "probably the very worst magneto-electric machine ever made." The whole apparatus as set forth in the patents, exhibited, in truth, a childlike ignorance, not merely of the requirements of electric lighting, but even of the most elementary principles of general science.

Nearly a year of time, as well as a vast amount of money, was expended in a fruitless attempt to produce a commercial incandescent lamp from platinum or iridium; but, at the best, the results do not appear to have been equal to those which had been attained by Farmer twenty years before. In the autumn of 1879 experiments were commenced with filaments of carbonized vegetable fibre enclosed in high vacua, which gave more encouraging results, and further progress in this direction led to an ultimate solution of the most difficult portion of the problem. In this new direction, however, the essential point of Edison's labors now proves to have been anticipated by W. E. Sawyer and Albon Man. The applications of the rival inventors were placed in interference in the Patent Office in the early part of 1880, and it is not until within a short time that the prolonged contest which ensued was finally decided by the Commissioner of Patents in favor of Sawyer and Man, awarding to them priority over Edison in the invention of an incandescent conductor of carbonized fibrous material enclosed in a transparent, hermetically sealed chamber, essentially the so-called Edison incandescent lamp of to-day.

In the meantime Hiram S. Maxim had also taken up the subject of incandescent lighting, and had produced, by a new process, a vacuum lamp having a filament of carbonized bristol board. A plant of these lamps was set in op-

Digitized by Google

eration in the vaults of the Mercantile Safe Deposit Company, in New York, in 1880, which was among the first, if not the very first, commercial installation of the incandescent system made anywhere. Maxim's patents passed into the possession of the United States Electric Lighting Company, and from that time forward a vigorous commercial competition was carried on between that organization and the Edison company. For some time there seemed to be but little difference in the merits of the two systems, but of late, owing to the important improvements introduced by Edward Weston, the system of the United States company has apparently been rapidly gaining in public favor.

The Edison company has persistently claimed from the first to hold the fundamental and controlling patents for incandescent lighting, but has until lately contented itself with reiterated assertions to this effect, without attempting to enforce its claims. It is difficult to account for the policy which this company has pursued in reference to its patents, except upon the theory that its managers were well aware that their professed claims to the absolute monopoly of the art of incandescent electric lighting were destitute of legal foundation.

We give in another column a summary of the more important claims of the patents upon which suits have at length been brought by the Edison company against various defendants, from which it will be seen that the points claimed relate almost entirely to the construction of the incandescent lamp. Some of Edison's claims are certainly broad enough in terms to "cover the exclusive manufacture, sale and use of any and all practical incandescent lamps"; but whether these claims can be sustained is quite another matter. The fact is, that neither the incandescent light itself, nor the system of regulation and distribution now in use can be summarily monopolized in this manner by Mr. Edison. A great deal of very important work in incandescent lighting had been done long before by Professor Farmer and others, and both Farmer and Weston had been constructing successful dynamo-electric machines for years before Edison turned his attention to the subject. All the patents of Farmer, Weston and Maxim are owned by the United States Electric Lighting Company, which has also brought suits against the Edison companies for infringements of these patents.

An important factor in the situation is the recently issued patent of Sawyer and Man, which apparently covers the Edison lamp as now manufactured, and, in fact, any lamp having a carbonized filament of vegetable fibrous or textile material. This claim, however, clearly does not cover the Weston lamp, in which the filament is made of tamadine, a cellulose material without structure or fibre; nor can it, we think, be held to embrace the Stanley-Thompson lamp of carbonized silk fibre. During the long contest in the Patent Office which preceded the issuance of this patent, the Edison company has had ample warning of the position in which it would be placed in the event of the success of the Sawyer-Man claim. We shall be very much surprised if Edison does not attempt to secure an interest in the patent, at least sufficient to protect himself, if not to enable him to enter with a reasonable prospect of success upon an aggressive campaign against some of his minor competitors who make use of similar materials in their lamps.

Even the Chinese have finally learned that, in modern warfare, victories are not to be won by the beating of gongs; no more can priority of invention be established by bombastic effusions in the daily press.

A BLOW AT THE AMERICAN PATENT SYSTEM.

It has been our inclination to refrain from comment upon the decision recently rendered by the Supreme Court of the United States in what is known as the Electric Railway Signal case, for the reason that the points decided arose upon the construction of the claims of a patent for an invention made many years since by the present conductor of this journal, and hence any opinions which we may feel called upon to express are necessarily open to the suspicion of being, in some measure at least, prompted by personal considerations, although the ownership of the patent has long since passed into other hands. We have however received an unsolicited communication upon the subject from a patent solicitor and electrical expert of the highest standing in a neighboring city, which will be found in another column, wherein the extraordinary and unprecedented character of the findings of the Court are forcibly pointed out. In order to enable our readers to judge for themselves whether the criticisms of our contributor are just or otherwise, we have also printed the full text of the opinion.

The far-reaching importance of the decision lies in the fact that it strikes at the very root, not only of most electrical patents, but of all that extensive and valuable class of patents in every department of industry in which a new and improved result is obtained by a novel combination of elements, each of which elements, separately considered, is old and well-known. A reference to the specification and claims of the patent at issue, which will be found quoted at length in the opinion as reported, shows that it was intrinsically nothing more than one of the simplest and most frequently recurring cases of a combination patent.

The object of the invention was the automatic operation of block-signals upon railways, by means of electro-magnets and circuit-closers actuated by a moving train. Mechanism for displaying and concealing visual signals by electromagnetism was well known, while the closing of an electric circuit by the action of a moving train was equally familiar to all electricians. Great numbers of circuit-closers had been invented, mainly of three classes, viz.: those in which the wheel depresses a pedal or lever and closes a key, those in which the deflection of the rail under the weight of the locomotive performs a like office, and those in which a section of the rail itself is insulated and the electric connection is completed by the metallic contact of the wheel therewith. The automatic block-system *per se*, which has long been public property, consists in placing a series of these signals along the line of the railway, each provided with its individual circuit-closer, battery and connecting wires, so as to be operated in orderly succession as the train progresses. The complainant's patent was for a system of circuits combining these old devices in a new way, and the invention, briefly stated, consisted in carrying two continuous battery wires along the line of the road, so that

Digitized by Google

all the signals of the series could be operated from one central battery, instead of a number of detached local batteries, thus greatly increasing the utility and lessening the expense of the system. Obviously it was wholly immaterial what particular construction of circuit-closers or batteries, or signal mechanism, or conductors, or insulators, were used, the organization of circuits being the essence of the invention, and not the devices. The defendants used a different circuit-closer, a different signal mechanism, and in part a different conductor, but they nevertheless substituted a perfectly well-known equivalent for each individual element of the patented combination, whereby they were enabled to accomplish precisely the same result, and to gain precisely the same advantages.

The decision of the Supreme Court, therefore, states the law to be, that any patent for a new combination of old elements, by which a new result is produced, may be infringed with impunity by substituting for any one of these elements another equally well-known one capable of performing the same function, provided it is not identical in its construction. It is within bounds to say that fully 95 per cent. of the commercially valuable electrical patents now in force in the United States are of precisely this character, while the proportion in other branches of industry is probably but little less. It is the importance of these facts and the character of the results which must flow from this precedent which must serve as our apology for directing special attention to a matter, which, under other circumstances, would have concerned the parties interested alone, and have been without significance or importance to the general public.

There has, for some years past, been a feeling among inventors and patent owners that the Supreme Court, as at present constituted, is developing a growing hostility towards the entire patent system of the United States, as it has heretofore existed since its reorganization in 1836.

This policy was manifested in the first instance in the remorseless and wholesale slaughter of all reissued patents which have of late years come before the Court for adjudication, commencing with the case of *Miller* vs. *Bridgeport Brass Co.*, in 1882, although it is not too much to say that the majority of these have perhaps deserved no better fate. The present decision affords a strong indication that a similar policy is hereafter to be pursued towards original patents. There can be no doubt that the precedents now laid down are sufficient to ensure the defeat of any patent which may hereafter come before the Supreme Court, in which the invention of the patentee resides wholly in the novelty of a particular combination. This, as we have said, is the case with the majority of the patents now in force.

ON THE USE OF WINDMILLS IN ELECTRIC LIGHTING.

The newspapers of a neighboring city have recently been filled with column upon column of what is by a polite fiction termed "matter," relative to what is going to be done by a certain combination which has recently been formed in the electric lighting business. We venture to suggest that this organized system of newspaper electric-light puffery, whether gratuitous or paid for, is getting to be decidedly overdone. It has reached a point where it has become nauseating. The new "combination," so far as appears, amounts to nothing more than an agreement between two existing companies, one of which sells arc and the other incandescent lights, wherein it is provided that each party, in cases where it cannot sell its own system, will endeavor to introduce the system of the other party; an ingenious practical application of the principle of the donkey race, in which each competitor rides somebody's else donkey, and the one who comes in last wins the purse. This is all well enough, but why make such a to-do over it? Why should an electric lighting company owning a good system, capable of holding its own ground on its intrinsic merits, which is the case with each of the concerns we refer to, descend to such clap-trap advertising, shallow puffery, and general "striving after wind?" In view of the experience of the past few years, what prudent investor can be expected to risk his money in an enterprise carried on by such methods, and by the class of promoters who do their business in that way? The past record of some of the persons most prominently concerned in the speculative electric light enterprises of to-day, is by no means of a character to render precaution superfluous. Under the specious plea of "enlisting the support of local capitalists," it is to be feared that many persons will be induced to invest their little savings in electric lighting enterprises, which are springing up like mushrooms in many places where there is no possibility of a remunerative business, from whence they will eventually find their way into the pockets of these thrifty financiers.

If there are people who feel that they *must* invest their money, there is the Bartholdi Pedestal and Children's Fresh Air Fund, both worthy objects, neither of which will return any dividends, nor can the shares be transferred to other victims, but in the one case at least there will be something to show for the money That is more than can be said for a large proportion of these "local" electric lighting schemes.

THE LEWIS SELF-BINDING INSULATOR.

In his article on the construction of lines for electric circuits, Mr. Thomas D. Lockwood, on page 89 of the March number of this journal, referring to the Lewis self-binding insulator, states that the conception of forming the outside screw in a direction opposite to the internal screw, in order to provide for the simultaneous attachment of the insulator to the line wire and the pin, is due to Frank L. Pope. This statement although technically correct, inasmuch as the device was patented to Mr. Pope on December 25th 1883, in justice to Mr. Lewis, requires an explanation. The invention was original with Mr. Pope, but after the issue of his patent, he for the first time learned that Mr. Lewis had at an earlier date conceived the same invention, and had embodied it in insulators manufactured under his supervision in England. While this circumstance does not of course impair the validity of Mr. Pope's patent, yet there can be no question that Mr. Lewis was a prior and independent inventor of the same device, and it is a matter of simple justice that he should have due credit therefor. In preparing his article, Mr. Lockwood of course had no access to other sources of information than those afforded by the records of the United States Patent Office.

ARTICLES.

A FOREGONE CONCLUSION.

BY WALTER P. PHILLIPS.

It will always remain, I suppose, an open question whether Mr. Vanderbilt said it or not. However, if he did say it, he said a very sensible thing. What does the public know or care about what is being done for its benefit? My experience has been that the public wants not only this terrestial ball, but, if left to itself, it is disposed to be captious about the color of the ribbon with which the earth shall be tied up when it is presented, and, on the whole, the "dear people" are quite as well off when their thinking, on intricate subjects with which they are unfamiliar, is done by experts.

Can there be but one opinion about the condition of the telegraph business as we find it to-day? Does any one, who knows anything about it, dare deny that telegraph property is losing its value; that the men and women who follow the business for a livelihood are discouraged by the outlook, and that the service is degenerating? And if I ask who has been benefited by the "rate war," which has led to the deplorable condition of things as they exist, I shall be told that the public has had the benefit of the competition. I hope the public appreciates this advantage; but when we come to analyze the matter it will, no doubt, be found that while a good deal of damage has been done, the benefits derived are not of corresponding consequence. Indeed, I shall venture the declaration that no work which is done at less than cost is performed as satisfactorily to the payer as when it is done at a profit. Men and corporations find it cheaper, in the end, to pay large fees to good lawyers than small fees to bad ones. The man whose wife or child hovers on the brink of the grave employs the highest-priced physician he can find; and so this idea of paying handsomely, as a matter of absolute economy and safety, pervades our whole system of commercial and social life, as applied to all matters of importance.

Assuming that I am right in the foregoing conclusion, the question narrows down to whether or not the convenience of instantly exchanging communications between distant points is an important or an unimportant matter. As a large employer of the telegraph, I have no hesitation in saying that it is one of the most important matters imaginable, and I shall argue the case from that point of view. A reduction of rates has invariably resulted in a deterioration of service. When the rates were at a fair and equitable figure the salaries of employés were kept at a point sufficiently high to retain the cream of the profession in the business. With the reduction of rates—a scourge upon the companies and their employés—all the operators who could get away from the general telegraph offices lost no time in going. As is usual, the best men were the ones who departed first, and probably a larger number of them have found comfortable places of refuge during the past year than during any three years preceding. With their earnings reduced below a paying point, through competition, the companies had no course open to them but to curtail expenses, and this has been done by gradually filling the places of first-class operators, as vacancies occurred, with men, women and children of second, third and fourth-class ability. The public gets the benefit of having its business handled by these youthful apprentices, and the yahoos from the highways and byways who have been brought in simply because they can be hired cheaply. In many cases offices have been turned over, even in cities of some size, to a mob of illiterate and irresponsible boys. The public, which once had its business transacted at living rates, by men of intelligence, education, zeal and care, now has it slaughtered, in many cases, by persons unfitted for telegraphic work. But the public gets its work done cheaply, you say. If paying 10 cents for sending a telegram from New York to Boston, and having to hire an interpreter to decipher it; or if getting the benefit of a 15-cent rate to Chicago, and having to spend half a day getting messages repeated, constitutes a net saving, then I am not a good mathematician. It all reminds me of the simple fellow who fancied he was being helped, on his way from Buffalo to Albany, by a canal-boat, because he was permitted to drive the horse and trudge along the towpath on foot.

I do not mean to say that there are not thousands of superb operators in the employ of the numerous companies, or that much of the telegraphing is not better done to-day than it has ever been done before in the history of the business. But I do insist that the average work is far inferior to what it was 10 years ago, and that the tendency of the business is downward. I maintain that the effect of low rates, with their inevitable accompaniment of reduced salaries, has been to drive the best men into other pursuits, and to let in the men whom nature intended for hewers of wood and drawers of water. I believe that this is all wrong, and that all telegraph men, all business men, and all sensible folks everywhere, should welcome any change in the situation that is calculated to relegate these apprentices to their primeval obscurity, and tempt back into the business the bright, zealous and conscientious experts who are being crowded out of it. Higher rates, better salaries and fair profits are the only agencies that will work this change. The telegraph business, as it is running now, is making alarming progress toward the bottom of the hill; and, in my judgment, it is altogether too valuable an adjunct of civilization to be allowed to go to utter ruin without a protest from all sides.

The rate cutting began in earnest with the advent of the American Rapid Telegraph Co., an organization which operated a so-called "fast" system. This company entered the field with the avowed purpose, as announced in its pamphlet, of "moving the United States mails." In the zenith of its career, when its automatic system was in full feather, and after it had sunk for its promoters several millions of dollars, the "Rapid" was equal to the emergency of getting a telegram from Boston to New York in three or four hours. Its rates were low; it was as disregardful of the text as a dissenting preacher, and it employed a collection of human curiosities, the like of which the world had never seen before, and which I hope a kind fate may save us from ever seeing again. I remember that an agent of mine, who had gone over to New York, employed the "Rapid" line in informing me, at Washington, what he had accomplished. His telegram arrived about noon, and read: "The whole matter has been refused to George D. Forrest for the invitation of reporters. Shall be home in the morning." I did not know Mr. Forrest, but I naturally regretted that anything had been refused to him. However, I was glad, in a fraternal sort of way, that the reporters had been invited, and, taking it all around, everything seemed to be shaping itself admirably. But I didn't know what it all meant, and, up to 10 o'clock that night, the Washington manager hadn't been able to clear up the mystery. However, my agent was coming home in the morning, and that was comforting, for on his arrival I should be let into the secret at which he so darkly hinted. I went home wondering how much economy there was in sending for 15 cents 20 words that people couldn't understand, when for 30 or 40 cents my telegram might have been sent by the Morse lines and delivered to me so as to be intelligible. That and dozens of similar experiences have convinced me that the best telegraphing is the cheapest, and my view tallies very closely with that of hundreds with whom I have compared notes at different times, and some of whose experiences were funnier than mine. The enigmatical telegram, as filed in New York, read: "The whole matter has been referred to General Eckert for investigation and report. I shall be home in the morning." The agreeable and courteous general probably does not know that he once figured as "George D. Forrest;" but

Digitized by Google

great and small suffered alike when the perforator, the person who turned the crank, and the typewriting young woman of the old "Rapid" days had manipulated a name; and General Eckert was not more badly treated on this occasion than Mr. I. A. Sherman, the general superintendent was, every day or two, when he was transfigured and made to appear as "Jasherman." It has often been asked how the Rapid company managed to keep the field. The secret of its continued existence, hampered as it was by a system that was certainly unique, rested in the fact that setting out with men like Gerritt Smith, H. J. Pettingill and George Hinman, it always had in its employ a sprinkling of excellent Morse operators, and those men leavened the whole loaf. These Morse men finally saved the credit of the company by gradually introducing Morse; and while it was out of the question to make the concern pay, on the basis of 15 cents for 20 words, the "Rapid," from doing the worst telegraphic work, came to do as good Morse work as was ever done by any company. Finally, it was overborne by the telegraphers' "strike," and when it recovered from that and adopted the Western Union rates, it went on with a moderate degree of prosperity, until its officers listened to the song of the siren and surrendered their property into strange hands.

Mr. A. W. Dimock shot across the telegraphic horizon like a meteor. In an incredibly short space of time he had merged the Bankers and Merchants', the Rapid, the Southern, the Board of Trade, the Pacific Mutual, the Michigan Postal, and I don't know how many other companies under one management. He brought about him capable telegraph men, and the word went forth that the greatest opposition system that had ever been projected was about to be established. It certainly looked so at one time; but one sad day, about a year ago, when there was a flurry in Wall street, bright little Mr. Dimock turned up very badly bent, not to say absolutely broken, and the name of the Bankers and Merchants' has been a synonym for pecuniary distress from that day to this. Its financial embarrassments and the competition, at low rates, by the Postal Telegraph and Cable Co. have made bad matters worse. The former company has been forced to reduce prices or close its doors. Simultaneously it has been the sport of receivers and the prey of lawyers, and in the short time the court has had it in charge it has run behind nearly $200,000, while its floating debt is a thing of infinite variety. Meantime it is currently reported, and is probably true, that the Postal Telegraph and Cable Co. will soon go into the hands of a receiver or be "re-organized." So we have thus far the Rapid, the Bankers and Merchants' and the Postal companies, whose attempts to do telegraphing for practically nothing have ended in complete and overwhelming disaster.

The rate cutting inaugurated by the Rapid, drifted into by the Bankers and Merchants', and taken a hand in by the Postal, has also been carried on with vigor by the Baltimore and Ohio and the Western Union, the latter making its fight through branch offices, where the banner of the absorbed and virtually defunct Mutual Union is thrown to the breeze. These companies are both rich and can stand going to war if they like it better than peace. All the same, much business is no doubt drawn from the Western Union, and done at a loss by the arrangement that company has for using Mutual Union stationery and accepting Mutual Union rates. As for the Baltimore and Ohio, its best friends are not certain it is paying expenses, while it goes without saying that if the Western Union were doing a business which investors and speculators believed would enable it to continue the regular payment of dividends, its stock would not be selling at 59¾—the market price as I write.

Having glanced cursorily at the most prominent features of the case, I reach the conclusion that the Bankers and Merchants' and the Postal must go to the wall; that the curtain must be dropped on the Mutual Union divertisement, and that the Baltimore and Ohio and Western Union, succeeding to the entire telegraphic business of the country, must arrange between themselves to charge higher rates. The employment of a better grade of operators would naturally follow, and the public, instead of having cheap work at ruinous rates, would have good work at fair rates. Whether the bankrupt companies shall turn their property over to the Baltimore and Ohio or the Western Union, or whether it shall be sold at forced sale to whomsoever will bid for it, is a question. But that the lines, outside of the Baltimore and Ohio and the Western Union, cannot be operated, except at a loss, is so palpable a fact that no one is likely to dispute it. A country as large as this, is surely entitled to two telegraph systems, and both should be first-class. A combination of all telegraphic interests would precipitate the government telegraph at the next session of Congress, and it is safe to assume, I think, that neither Mr. Gould nor Mr. Garrett would relish having the government as a competitor. As between a telegraph monopoly, in private hands, and the governmental control, I should favor the latter. But if two comprehensive and efficient systems of telegraphs can be kept in the field, it will be better for the public and for employés than one system conducted by the post-office department. The existing situation presents a problem that will, perhaps, solve itself in the near future; but so far as I can see, it is susceptible of but one solution—the one I have outlined herewith.

THE EDISON CLAIMS SUMMARIZED.

The Edison Electric Light Co., having at length completed their preparations, commenced on May 2, 1885, a number of suits in the United States Circuit Court for the Southern District of New York, against the United States Electric Lighting Co., the United States Illuminating Co., the Consolidated Electric Light Co., and the Swan Incandescent Electric Light Co., for alleged infringements upon the patents of the Edison company relating to incandescent lighting. Additional suits have been instituted against a number of representative users, among others the National Park Bank, and the Mortimer estate using the Weston system, and the First National Bank, the Bank of the Republic and W. H. Jackson & Co. using the Consolidated or Sawyer-Man system. Thirty-four different suits are brought against the United States Electric Lighting Co., its licensees, and customers, alone.

The Edison company claims that its patents cover the exclusive right to manufacture, sell and use, all practical incandescent electric lights. Edison himself asserts that "subdivision" and "high resistance" are his discoveries, and the great principles upon which his patents are based. The claims of the patents themselves, serve very well to show the position of the *prima facie* case of the Edison company, and we accordingly subjoin all those which appear to be of importance, in the several patents upon which suits have been brought.

The first group of patents relates to the construction and manufacture of incandescent lamps, and the essential claims are as follows:—

Edison's patent No. 227,229, filed April 21, 1879, issued May 4, 1880.

> In an electric lamp, the combination, with a hermetically sealed vacuum-chamber made entirely of glass, of metallic conductors passing through the glass and around which the glass is melted, and an incandescent conductor placed in the electric circuit.
>
> The method herein specified of treating metallic conductors for electric lamps, consisting in inclosing the conductor in a glass case, exhausting the atmosphere from such case, heating the conductor by an electric current, and then hermetically sealing such glass case.

Edison's patent No. 223,898, filed Nov. 4, 1879, issued Jan. 27, 1880.

> An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance, made as described, and secured to metallic wires.

Digitized by Google

The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass, and from which receiver the air is exhausted.

Edison's patent No. 230,255, filed Feb. 5, 1880, issued July 20, 1880.

The method of forming electric lamps, consisting in separately forming the inclosing globe and the supporting bulb for the incandescent conductor, attaching the wires and incandescent conductor thereto, and then hermetically uniting the parts prior to the formation of the vacuum.

The method of hermetically sealing a vacuum-chamber, which consists in first sealing *in vacuo* and then sealing in air.

Edison's patent No. 239,153, filed Aug. 27, 1880, issued March 22, 1881.

The combination with the glass inclosing globe and incandescing conductor of a support hermetically sealed to the globe and supporting the carbons at a distance above the point of sealing.

Edison's patent No. 239,149, filed Dec. 15, 1880, issued March 22, 1881.

An incandescing electric lamp, the supporting neck formed with a concavity at the point where the leading wires pass through and are sealed therein.

The supporting neck formed with a solid glass projection, to and upon which the inclosing globe is supported and sealed.

Edison's patent No. 248,419, filed April 15, 1881, issued Oct. 18, 1881.

In an electric lamp, the combination of a piece of platinum sealed into the glass, and terminals of other metals affixed thereto, one extending into the lamp for union with the incandescing conductor, and the other protruding therefrom for connection to the ordinary conductor.

Edison's patent No. 266,447, filed April 26, 1881, issued Oct. 24, 1881.

The method of manufacturing incandescent electric lamps, consisting in forming the inclosing bulb or globe directly from molten or pot glass, forming separately the supporting tube or neck for the incandescent conductor, sealing therein the leading-in wires, attaching the carbon thereto, and then hermetically uniting the parts by a welding together prior to the exhaustion of the lamp.

A leading-in wire composed of a central platinum section for sealing into the glass an outer section and an inner section, having a clamping device formed integral therewith.

Holzer's patent No. 264,698, filed Nov. 28, 1881, issued Sept. 19, 1882.

The method of sealing the leading-in conductors into the central tubular carbon support of an incandescing electric lamp, consisting in squeezing the open upper end of the tube upon such conductors and at the same time closing air-tight such end of the tube.

The second group of patents relates to the material and mode of treatment of the carbon filament as follows :—

Edison's patent No. 251,540, filed Aug. 6, 1880, issued Dec. 27, 1881.

An incandescing carbon conductor for electric lights, made from cane, bamboo or similar fibre.

Edison's patent No. 265,777, filed Dec. 15, 1880, issued Oct. 20, 1882.

The method of treating the carbon filament of an incandescing electric lamp, consisting in raising such carbon filament to a higher incandescence than that at which it is designed to be used, during the latter part of the process of exhausting the lamp-globe, whereby the air and gas are driven from the carbon filament and from its enlarged ends and clamps, and the flexibility of such filament is increased and its shape fixed.

Edison's patent No. 307,029, filed Oct. 12, 1882, issued Oct. 21, 1884.

The process of forming the flexible incandescing filaments of electric lamps, consisting in first forming a straight filament of carbonizable substance, then carbonizing the same, and finally bending the flexible filament thus formed into the desired shape.

The third group of patents relates to the mounting of the incandescent lamp upon its supporting fixtures as follows:—

Edison's patent No. 265,311, filed Feb. 5, 1880, issued Oct. 3, 1882.

A separate electric lamp, consisting essentially of an inclosing globe entirely of glass, an incandescing material secured therein, conductors leading thereto and sealed in the glass where they pass there-through, and a base of insulating material in which the neck of the globe is secured, said base being provided with metallic contact-plates to which the conductors leading into the globe are secured at their outer ends.

A socket for an electric lamp, adapted to be placed upon a gas-pipe or other suitable support, and provided with contact-plates forming the terminals of an electric circuit.

The combination of a separate electric lamp made and provided with a base as described, and a socket adapted to be secured upon a gas-pipe or other suitable support and provided with contact-plates so that the two may be readily attached and detached.

Edison's patent No. 248,424, filed Mar. 26, 1881, issued Oct. 18, 1881.

The combination of a base-piece such as described, a lamp or chandelier standard, a safety-catch and a cap covering the base-piece.

The combination of a pendent incandescing electric lamp and a socket to which said lamp is removably attached, with an open-flaring reflector supported by means attached to or above said socket, whereby the downward reflection of the light is uninterrupted and the lamp can be removed from and placed in said socket without disturbing the position of said shade or reflector.

Edison's patent No. 251,554, filed Mar. 26, 1881, issued Dec. 27, 1881.

The combination, with an incandescent electric lamp and its socket, detachable from each other and adapted to be used in a complete or round wire circuit, of controllable means for positively holding them in position together, and means for automatically completing the circuit connections between them through both limbs or members of the circuit upon placing them together in position.

The combination, with a separately removable incandescent lamp and its socket, of means for holding them positively in position relatively to each other.

THE UNITED STATES COMPANY'S CLAIMS SUMMARIZED.

The United States Electric Lighting Co. have brought suits against the Edison companies, in the United States Circuit Court of the Southern District of New York, alleging infringements upon a number of patents of which it is the assignee and owner. Two of these patents relate to incandescent lamps, and contain among others, the following claims :—

Maxim's patent No. 244,277, filed Dec. 8, 1880, issued July 12, 1881.

In an electric lamp, a continuous incandescent conductor inclosed in a transparent vacuum-globe, in combination with conducting-wires leading to said conductor, each of which is divided where it passes into the globe into two or more branches, to which the material of the globe is directly sealed by fusion.

Maxim's patent, No. 254,032, filed March 31 1881, issued Feb. 21, 1882.

In an incandescent electric lamp, the combination, with the conductors sealed therein, of a continuous conductor of carbon gradually enlarged at or near its ends.

Two other patents relate to the winding of the armature of the dynamo machine.

Weston's patent, No. 259,618, filed Dec. 31, 1881, issued June 13, 1882.

An armature wound with two systems of coils in diametrically separate divisions, the divisions of one system being alternately under and over those of the other, and the said divisions being looped together and connected to the commutator.

Weston's patent, No. 277,644, filed Jan. 9, 1883, issued May 15, 1883.

The combination, with an armature-core, of a system of conductors composed of massed strands or strips of conducting material.

The combination, with a cylindrical armature-core, of a system of conductors wound thereon, and composed of groups or bundles of fine wire, each group being spread out at the ends of the core.

The next two patents relate to the system of distribution and regulation employed.

Farmer's patent, No. 252,836, filed June 7, 1881, issued Jan. 24, 1882.

In an incandescent electric lighting system, the method of uninterruptedly controlling the strength of current of a main line of continuous conductors by and correlatively with incidental variations of strength in the same current traversing a continuous branch circuit.

In an incandescent electric lighting system, the method of varying the strength of current of a main line of continuous con-

Digitized by Google

ductors by dynamic effects produced by variations of strength in the same current traversing a continuous branch circuit.

The combination of a generator of electricity, two or more separate branches or derived circuits connecting the poles or main conductors of said generator, one or more electric lamps included in each of said branches, an adjustable rheostat included in that portion of the circuit of the generator common to all the lamps and mechanism, whereby the resistance of said rheostat is diminished as the joint resistance of the whole number of lamps is increased, and the reverse.

Farmer's patent, No. 253,817, filed March 7, 1881, issued Feb. 14, 1882.

The combination of a rheostat, mechanism for increasing or decreasing the resistance of said rheostat, an electro-magnet included in the same electric circuit with the rheostat, or in a branch thereof, and a lever for controlling the action of said mechanism, which is normally balanced between the attractive force of said electro-magnet and a constant antagonistic force, and contact-stops for limiting the motion of and determining the action of said lever.

Another patent is for the fusible "safety-catch."

Weston's patent, No. 259,614, filed Jan. 5, 1882, issued June 13, 1882.

The combination, with a circuit or branch thereof, of a safety device which fuses at a temperature below the ignition-point of wood, paper, fabrics, or other like combustibles.

The combination, with an electrical conductor, of a strip or wire of higher resistance than the said conductor, and which fuses at a temperature lower than the ignition-point of wood, paper, fabrics, or other like combustibles.

THE CONSTRUCTION OF LINES FOR ELECTRIC CIRCUITS.

BY THOMAS D. LOCKWOOD.

(Continued from page 173.)

There are one or two other points on the attachment of insulators which it may be well to refer to.

If it is found that any insulator, when attached to a bracket, touches with its edge the shoulder of the bracket, that bracket should at once be discarded, as all the conditions of a bad escape are thus prepared. Before such a bracket is used it should be shaved off so that there is no contact except on the attaching screw; moreover, neither glass insulators, brackets nor rubber hooks should be attached horizontally, as such a method of attachment is simply preparing an easy way for a driving rain to enter the insulator—possibly to leave water standing in the hollows thereof.

STRINGING WIRE ON POLE-LINES.

The size of wire being decided upon, the coils are mounted horizontally on suitable reels, which may be placed in a wagon, and drawn by a horse from pole to pole, or which, in the case of more modest constructors, may be carried on a hand-barrow, or even carried on a short pole. The last named expedient seems, however, to be more crude than is necessary, as almost any amateur constructor can make a suitable reel, and mount it on a wheel or hand-barrow.

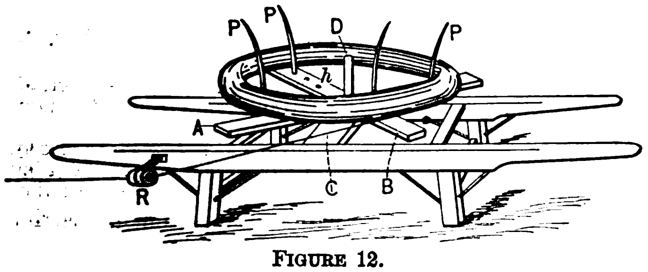

FIGURE 12.

The reel shown in the figure is a very handy one, and can easily be managed by one man.

The two cross-pieces, A and B, should each be about three feet long, two inches thick and three wide, and they rest on the stationary cross-bar, C, by means of the iron centre-pin, D, which may be about six inches high, and an inch and a half thick. The centre hole should be fitted with a bushing of iron; if the hole through the wood is made larger than the pin, a couple of iron plates may be made to serve instead of the bushing; they must be bored at the centre to fit the pin, and then fastened to the upper and lower surfaces of the cross-pieces, so that they will revolve easily on the pin.

A number of holes, *h*, may be bored in the cross-pieces, so that the pins, *p*, may be changed to fit reels of various sizes. A metal or glass ring, R, may be attached to an iron clamp, and fastened to the side of the barrow for the wire to pass through. Lieut. Swift, in his recent work, "The Practical Telegrapher," suggests for this purpose an ordinary glass insulator, with the top punched out. The number of men required to string wire varies almost as much as any other feature of the business. I have strung wire with but two men—one to climb, and one to watch the reel and pull up; but I have also worked a force with as many as six climbers, and it is needless to say that in the last case the work was done much quicker, and in some degree better, as many times circumstances occur in which a number of hands can be economically employed. Each climber requires a pair of good pliers, a pair of climbing spurs, and a supply of tie wires.

The reel is advanced along the line for some distance ahead, and before any wire is attached the person in charge should have the wire laid at the foot of the poles, and examined for faults and unsoldered joints, as no such defect ought to pass unremedied. When the end of the coil is reached, the beginning of the next should be jointed to it while a considerable length of the former is still on the ground.

The wire thus examined may be now picked up by the polemen, who, many or few, should all climb at once, the wire being thrown over their arms.

The tie-wire is made to embrace the insulator in the wire groove, and the line-wire is then placed in the opposite side of the groove over the ends of the tie-wire, which are then turned upward. Before completing the attachment the line-wire must be tightened up by the man or men in charge below.

This is best done with a block and tackle, but quite frequently has to be done by hand. When it is pulled sufficiently taut, the climber gives each end of the tie-wire a turn and a half around the line-wire, and then cuts off the ends, thus completing the attachment.

TIE-WIRES.

Tie-wires may be cut from the wire to be strung, and need not, as a rule, be more than 12 or 14 inches long. If the line conductor is a copper wire, the tie-wire must also be of copper; this is a most important point, and to use iron tie-wires for copper lines is simply to prepare future trouble, as galvanic action may be expected from such a combination. When a copper line is being attached, great care must also be taken not to twist the tie-wires too tightly, as the copper wire is liable to be cut into or otherwise damaged. A number of methods have recently been adopted to some extent with copper wire, in which the tie-wire is made to support the line-wire altogether, and is bound round it, as well as round the insulator; but, if well done, I regard the old-fashioned method as being equally serviceable.

STRAIN.

Very rarely in the United States is sufficient attention paid to the matter of strain, and yet it is one of the most important in line construction. The degree of tautness with which a line-wire is originally stretched frequently determines its durability. If a wire is pulled up too tight, it will sooner or later break; if left too slack, it will cross with others. How is the proper mean to be arrived at? This subject has been brought to an exact science in England, and we shall do well to profit by the practice which obtains there.

Digitized by Google

The maximum tension of any span should be one-third of the breaking strain. No. 8 iron wire, for example, has a breaking strain of 1,200 pounds, and the tension with which it is drawn up should therefore not exceed 400 pounds. No. 12 iron wire has a breaking strain of about 510 pounds, and should not be pulled up with a greater tension than 170 pounds.

But it will be objected, How is it possible to know what tension is given to a span without wasting valuable time, and putting more work into it than it is worth? This is where the results of experience are utilized.

It has been found that the dip of a wire, by which is meant the difference between the lowest point of the span and the level of the supports, is just about 24 inches in a span of 100 yards, when the tension is one-third of the breaking strain, and knowing this, we can readily apply it to spans of any length. The dip increases, not with the distance between the poles, but as the square of the number of times that the distance is increased. If, for example, in a span of 50 yards we have a dip of one foot, for double that distance, 100 yards, the dip will be 2×2, or four feet; for four times the distance, or 200 yards, the dip would be 4×4, or 16 feet. Therefore, if we wish to know what the dip of any span should be, on the standard of 24 feet to the 100-yard span, we simply multiply the original dip by the square of the length of the proposed span, and divide by the square of the length of the original span. Suppose, for example, that I wish to know the dip for a span of 80 yards, I multiply the standard dip, 24, by the square of 80, and divide by the square of 100, finding as a result the required dip to be approximately 15½ inches.

The mathematical formula is:

$$R^2 : \quad r^2 : : \ D : d \ or \ \frac{D \times r^2}{R^2}$$

R being the length in yards of the original span; *r* the length in yards of the proposed span; *D* the standard dip, and *d*, the proposed dip. From the above considerations *I* have deduced the following table:

Poles to the mile.	Dip of wire at centre of span.
15	34½ inches.
20	19½ "
25	12 "
30	8 "

It must be remembered that these dimensions are the maximum figures, and that they are calculated for a temperature of 60° F. They hold good, however, for all sizes of iron wire alike, and thus only one wire on a line of poles need be closely calculated for; the remaining wires only need to be pulled up parallel with the first. Wires strung in the summer, must be suspended a little slacker than those put up in winter, as iron wire expands about $4\frac{1}{10}$ inches per mile for every ten degrees of rising temperature. There is still another quite important point about strains—this is, that the tension is least at the centre of the curve, and greatest near the poles. In very long spans we may avail ourselves of this fact, to advantage, by introducing a lighter wire into the middle of the span. By so doing the ends will not have so much weight to carry, while the centre will still be strong enough to resist the lessened strain of the lowest point.

An important application of these rules lies in regulating the tension with which the supporting wires of aerial cables are pulled up. In many places I have observed that such suspending wires are pulled up nearly to a level. This however, is a most injudicious practice, as a wire so pulled up is too tight, even if it had no extra weight to carry. A wire so drawn up cannot be expected to stand well, and, moreover, places far too heavy a strain on the poles or supports. Much of the strength of a wire stretched to such a degree, is taken up in holding itself together against the constant tendency which its particles have to pull apart. Furthermore, if a wire is so pulled up in mild weather, it can scarcely be expected to stand in cold weather, when the strain will be enormously increased.

When copper wire is used, a new basis for calculation must be formed, as the standard of a dip of 24 inches in a 100 yards does not hold for any other metal than iron. It is still, however, proper to adhere to the maximum tension of one-third of the breaking strain.

It is clear, then, that we must, to find the maximum strain which should be allowed to copper wire spans, first ascertain the breaking strain or tensile strength of the copper wire, then taking one-third of that, note the dip produced in a 100 yard span (or a shorter span, according to the law of squares, referred to already), under a tension of that amount, which will give a new standard for copper wire.

No. 12 B. W. G. hard copper wire is found, for example, to average a breaking strain of 566 pounds; and, therefore, should be pulled up with a maximum strain of 188 pounds.

Where a wire runs through foliage which cannot be trimmed, short pieces of heavy kerite wire may with profit be inserted in the line circuit.

JOINTS OR SPLICES.

I suppose that defective joints have given rise to more trouble in electric circuits than any other single fault. It is really surprising how much annoyance a single bad joint can produce, and how much resistance it can introduce into an otherwise good line. This is due partly to the great number of splices in a line, partly to the too frequent lack of care with which they are made, and partly to the difficulty with which an imperfect splice is located, and to the impossibility of a close inspection, when the suspected splice is about midway between two poles. It is quite obvious, therefore, that jointing is one of the most important operations which a lineman is called upon to perform, and all linemen should be carefully instructed as to the absolute necessity of nothing less than perfection in such work. Each manufacturer's joint ought to be examined, while the wire is lying at the foot of the poles, immediately before stringing, and any found defective, or even suspected, should be cut out and made over. Although more attention is now justly paid to this branch of construction, than has been the case in the past, it is to be feared that even yet the extreme importance of extra care is underrated by the majority of persons engaged in line construction. Soldering every splice adds almost indefinitely to the working capacity of a line, yet comparatively few constructors regard joint soldering as being as much a part of their work as fastening the wires properly to the insulators. The consequences of neglect are, in fact, much more disastrous and far-reaching. No unsoldered joint should ever be permitted to go into a line. No twist-joint can, if left unsoldered, long stand the oxidizing powers of the elements.

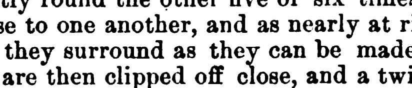

FIGURE 13.

The figure above well represents the characteristic American joint. It is not as neat a joint as some others, but it is easily made, hangs well together, and when thoroughly soldered constitutes a very good splice. In making it, the ends should first be brightened, and then put together and held by a vise, while each end in turn is wound tightly round the other five or six times, the turns passing close to one another, and as nearly at right angles to the wire they surround as they can be made. The extreme ends are then clipped off close, and a twist given to the middle of the joint, to bring the two wires into still more intimate contact, after which the joint is soldered and is then complete.

BOLLMANN'S DYNAMO.

BY OTTO GRÜNINGER, C. E.

(From private communications of L. Bollmann, of Vienna.)

ONLY a few weeks ago the first tests were instituted at Vienna with an experimental machine of this type. The results obtained were remarkable. With a total weight of the machine of but 1,540 lbs. (700 kilos), and with 775 revolutions per minute of the shaft, a current of 55 volts potential was generated, which supplied 700 incandescent lamps of 12-candle power each; every part of the machine, armature as well as field magnets, remaining perfectly cool. Varying the numbers of the lamps, a reduction from 700 to 100 caused a variation in the potential of the current of only five volts; between 300 and 100 lamps the variation in potential amounted to three volts, and between 700 and a single lamp the difference in potential was eight volts. Yet there were no special devices of any kind to regulate the current.

The actual capacity or limit of this machine in the generation of currents could not be established. The accomplished results having been beyond expectation, the shaft had been made only 1⅞ inch (48 mm.) in diameter, and it was already taxed beyond its safe torsional strength when supplying the powerful current for 700 lamps. When, therefore, 1,000 lamps were connected, the speed was reduced to avoid breakage of the shaft, so as to correspond to an admissible power. It was then kept constant at 725 revolutions per minute, and the number of volts dropped to 38.

Bollmann's dynamo belongs to that class of machines which contain no iron in the armature, and in which the induction in copper coils or conductors, while passing a magnetic field, takes place directly, and without the intervention of the alternately growing and vanishing magnetism of iron cores. The principal and characteristic feature is to be found in the peculiar construction of the armature disc, which admits of practically utilizing the whole available volume of the disc for conductors, every portion of which is assisting in the generation of useful currents, and which also, at the same time, admits of a most intense magnetic field. One arrangement of the stationary field magnets is another novel and interesting point.

In figures 1 and 2, A A is the bed-plate of the machine, with bearings for the driving-shaft, B; D is the armature disc, which, by means of a double flange, C, is firmly clamped and secured to the shaft. An insulating substance between the flanges and the disc prevents any undue contacts or connections. The two standards, E E, are bolted to the bed-plate, and form the supports for the stationary electro-magnets, G and F. These field-magnets are of small size only, and they are paired around the two standards in such a manner that poles of opposite polarity are always facing each other—with the armature disc between them—while, on the same side of the armature, or on each of the standards, north and south poles follow one another around the circle. The machine, as shown in the drawings, has 16 pairs of such magnets. They are either arranged in the manner described, and as represented by the magnets, G G, in which case the pole-pieces approach the disc, D, as closely as possible without obstructing in the rotation of the latter, and all the poles are active in producing magnetic fields; or Mr. Bollmann connects in a novel manner every second pair of magnets around the disc by a bridge-piece, F, figure 2. In figure 1, the pair of magnets connected in this manner is also designated by the same letters, F F. The bridge-piece neutralizes the free magnetism of the magnets, F F; but as these latter are in metallic connection with the next following pair, G G, through the iron standards, E E, the free magnetism of these magnets, G G, or their magnetic field, is doubled in its intensity. The pole ends of F F and the bridge-piece, not acting themselves directly upon the disc D, are shaped so as to give ample room to the rotating-disc

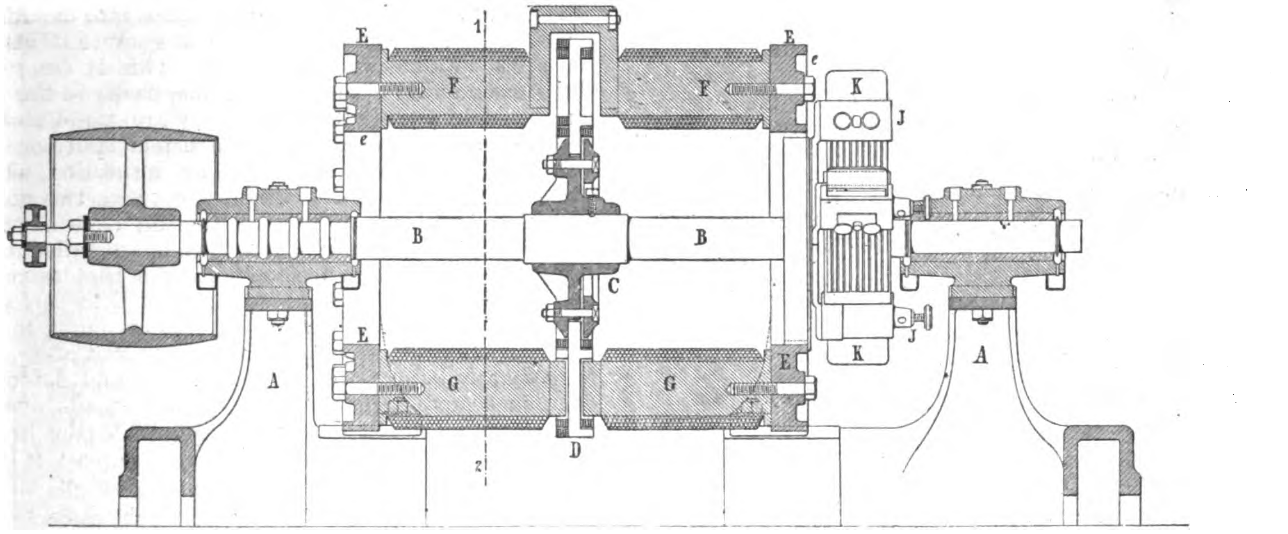

FIGURE 1.

In this manner all open and active north poles are on one side of the armature, and all open and active south poles are opposite to the first ones, on the other side of the armature. The inducing qualities concerning the generation of currents within the armature remain practically unaltered by this second mode of arranging the field magnets, as we will explain further on, but the stability of the machine with regard to its mechanical construction is much increased.

In order to remove the shaft, B, with armature, easily and without dismantling the whole machine, the standards, E E, are built open at the top at *ee*, and the openings are closed by removable segments, to which one or more of the field magnets are attached.

The most essential part of the machine, the armature disc, is constructed of straight radial parts, P, figure 3, and of parts R, figure 4 (both figures in elevation and plan), which latter are concentric to the shaft and shaped according to their relative distance from the centre. These parts, P and R, are all of copper. The concentric parts, R, have their ends bent at right angles to their planes, as shown in figure 4. Then P and R are connected as shown in figures 5, 6 and 7, in elevation, side view and plan; the different connections at *a*, *b* and *c* being made by riveting or by soldering. $P_{,}$ and $P_{,,}$ are the radial parts; $R_{,}$ and $R_{,,}$ are the concentric parts, the lengths of which must always cor-

respond to their relative distances from the centre, and to the angular distance between $P_{,}$ and $P_{,,}$. The end, *d*, of $R_{,,}$ is for the present free and without contact. Such a combination of two radial parts or strips with two concentric parts or strips may conveniently be termed an *element* of the armature, which element, instead of being built of four different pieces, could also be made partly or wholly of one piece of copper.

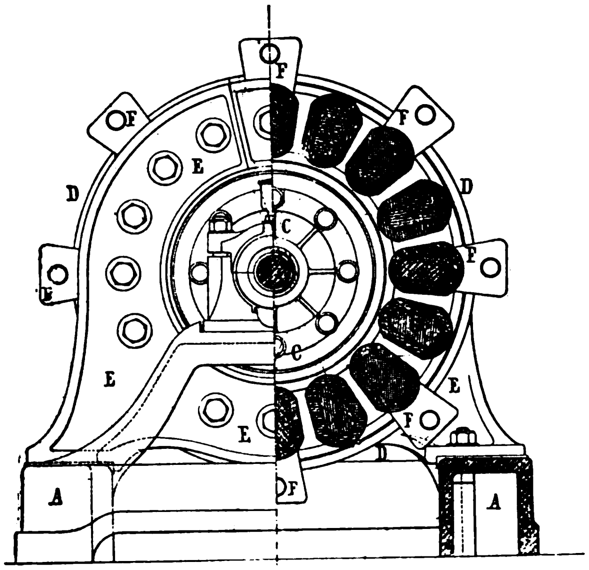

FIGURE 2.

A *second* element is then made, similar to the first one, but sufficiently smaller in the angular distance of its parts, P, and also correspondingly shorter in the lengths of the bent-up portions of its concentric parts, R, so that it may just be laid completely within the *first* element without touching anywhere except at *d*, where $R_{,,}$ of the first element is fastened, by riveting or soldering, to $P_{,}$ of the sec-

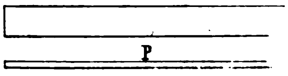

FIGURE 3.

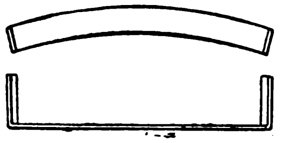

FIGURE 4.

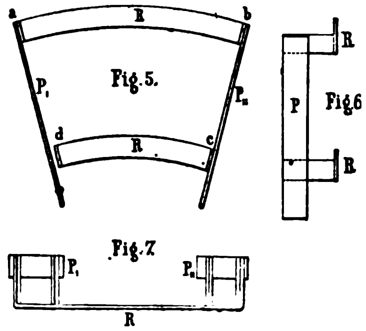
ond. A similar *third* element is snugly laid within the second one, connecting and being in contact only through the end-point, *d*, of this latter. In the same manner a number of such elements, usually from five to six, are placed within each other, each one a little smaller than its



immediate predecessor; the concentric part, $R_{,,}$, however, being omitted with the last and innermost of these elements. The different elements are kept apart by narrow strips of some insulating material, which are laid between the radial parts at their ends, so that the air can circulate freely between all of the elements,

Such a combination or group of from five to six elements—forming a consecutive spiral course in a manner that a current, entering at $P_{,}$ of the first and outermost element, has to circulate through all of the elements one after the other, leaving at $P_{,,}$ of the last one—has been called by Mr. Bollmann a *sector* of the armature. It consists of from 10 to 12 radial parts, P, and of from nine to 11 parts, R.

The angular distance between the *medium* element of a sector must be equal to the angular distance from one pair of field magnets to the next following one, or with reference to the figures which show 16 pairs of field magnets, the medium angular distance of the elements of a sector must be equal in this case to the $\frac{1}{16}$ part of a circle. Each sector, therefore, will always be subjected to the simultaneous inductions of two succeeding pairs of magnets.

The armature disc is now composed of a number of such sectors. One-half of them is made shorter in the radial parts than the other half, and this leads to two distinct sets of sectors with reference to the positions of their parts, $R_{,}$ $R_{,,}$, from the centre. The rationale of this is readily understood when the different views of the armature disc are examined, as shown in figures 8, 9 and 10*a*. From figure 9 it will be seen that the radial parts of all the different sectors form one continuous lattice-like disc, and this packing or nesting of the sectors into one disc is only possible when the concentric parts, R, of the different sectors are able to pass each other without interference or mutual contact. By having them bent, as has been described, by arranging them at different radial distances, and by placing them sometimes behind and sometimes in front of the disc, as may be required and as shown in the drawings, this feat is accomplished. Sometimes, especially with large machines, it may be found convenient to make the sectors of more than two different lengths in their radial parts, which, of course, will then lead to more than two sets of concentric parts, $R_{,}$ $R_{,,}$.

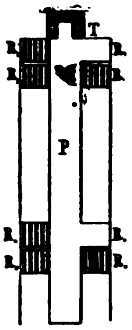


FIGURE 8.

Beginning in figure 9, to the left, the first two numbers, 1,1, represent the radial parts of a sector; the adjoining, next following sector is designated by 2,2; then comes sector 3,3, and finally sector 4,4. The sector which follows next to 4,4 is again numbered 1,1, because, according to the disposition of the drawing, this sector possesses exactly the same relative position to the field magnets as did the first sector, 1,1, and therefore it will, at all times and in all positions around the magnetic field, be similarly induced. This can be said of all sectors which are numbered 1,1; and, similarly, all sectors numbered 2,2 will always be simultaneously induced alike, and so on. The whole disc, therefore, consists of four different and distinct groups or series of sectors, for each of which the inductions will always be alike throughout, and any

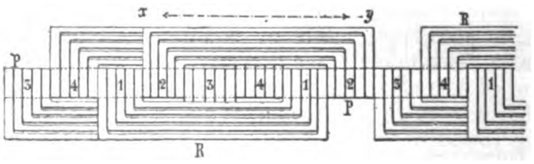

FIGURE 10*a*.

four consecutive sectors will always belong to these four distinct series.

Attention must here be called to a slight discrepancy in the drawings. In figures 10*a* and 8 the sectors are represented as consisting of five elements each, while in figure 9 the number of the elements in each sector is six. In the following we will assume each sector to contain five elements only.

The four series of sectors are connected into four separate circuits, and in figure 9 the connections for series 1

Digitized by Google

are indicated. $P_{''}$ of the innermost element of a sector, connects with $P_{'}$ of the exterior element of the next following sector of the same series. The connecting pieces are placed within recesses of the clamping flanges, C, and cannot be seen in figure 1.

Each series, therefore, consists of eight sectors and 80 radial parts, P, and the whole disc is built altogether of 320 radial parts, P. The inductions in the four series follow one another, so that, while the induction is most intense in one of the series, two others are only partially induced, and the fourth is in a neutral position.

The disc is fastened to the shaft by the clamping flanges, C, as already described; but, in order to more firmly secure the different elements of the disc in their relative position to each other, an outer clamping ring, T, may be used, as shown in figures 8 and 9.

To obtain a most intense magnetic field the pole-pieces of the field magnets must approach the radial parts, P, as closely as possible; and it is also of importance that the concentric parts, R, be as close as possible to the pole-pieces, because useful currents are induced in both P and R. The pole-pieces are therefore arranged to project into the annular space formed by the concentric parts, $R_{'}$ $R_{''}$, and as shown in figure 1 at G G.

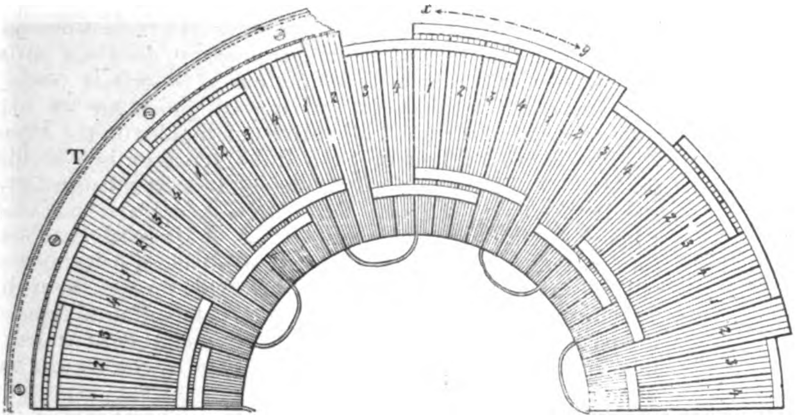

FIGURE 9.

The connections of the different series with the commutator may be made in different ways. For currents of low potential the two ends of each series may be led directly to the commutator, where connection is established with the external circuit as long as the potential of the induced currents in the armature is higher than that of the external main current. To secure good action the two potentials ought to be alike when the brushes make or break contact, and in order to accomplish this the brushes are made in pairs, which are adjustable, so as to cover a proper angular distance of the commutator. Two, and sometimes three, of the four series of the armature are simultaneously connected with the external circuit. For currents of low potential the pole-pieces should also be comparatively broad, whilst for currents of high potential the pole-pieces should be narrow, so as to concentrate the field. The different series may also be combined into one single continuous course, and branches be led off from it to the commutator, similarly to the connections of the ordinary Gramme ring. In such a case it is preferable to have more than four series in the disc, and this can be attained, for instance, by an arrangement of the sectors in the disc as exhibited in figure 10*b*. The length, *x y*, corresponds to the angular distance of two succeeding pairs of magnets. Only one-half of the radial parts, P, are shown in the drawing. The other half occupy the square places, which are left blank in the diagram for the sake of clearness. It will be noticed that there are now seven series in the disc, each of which may again be divided into two, if the field-magnets are chosen and distributed accordingly. The pole-pieces should then be made narrower, and fewer magnets (say from 10 to 12 pairs) ought to be used. The neutral zones are thus broadened, and sparks will be avoided at the commutator.

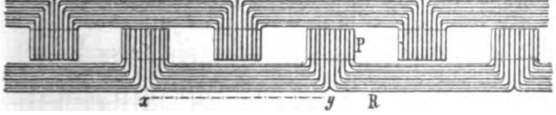

FIGURE 10*b*.

The commutator being of ordinary construction is of no particular interest.

Having thus described the essential parts of this new dynamo, it may be of interest to explain how the inductions actually do take place in the different conductors of the disc. To simplify matters we will assume the field magnets, instead of being arranged in a circle, to follow each other in a straight line; we will further assume the pole-pieces to be of a rectangular section, and we will move one single element along the line of the magnets, and observe in which manner its different parts are induced. The element in this case is supposed to be so constructed that its inner concentric part, $R_{''}$, instead of turning to the left of $P_{''}$, figure 5, is turning to the right. The diagrams in figures 11 and 12 illustrate this assumed state of affairs. The shaded rectangles represent the pole-pieces on one side of the armature, and facing the observer. South (*s*) and north (*n*) poles are following one another alternately, and the heavy zigzag line represents the moving element. The direction of the motion is from the left to the right, as indicated by the horizontal arrow.

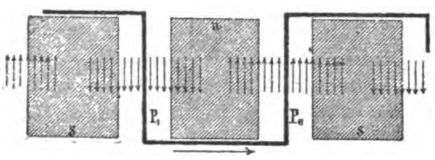

FIGURE 11.

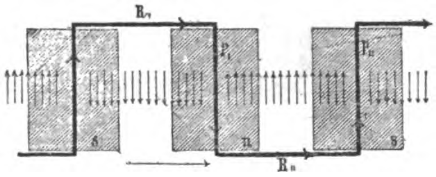

FIGURE 12.

According to the hypothesis of Ampère, a magnet can be substituted by electrical currents which encircle its axis, and this substitution can be adopted here the more readily, as we have only to deal with the external action of the field-magnets. Whatever be the true courses of these electrical currents, the directions of which are well known according to the polarity they are to represent, these courses must be coördinate to the central lines, *x x* and *y y*, figure 15. Decomposing the various elementary currents of the different courses into vertical and horizontal components, as shown in figure 15, for one course of a north pole and its analogous course of a south pole, and selecting four coördinately situated elements, *a*, *b*, *c*, *d*, and also

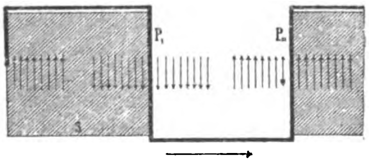

FIGURE 13.

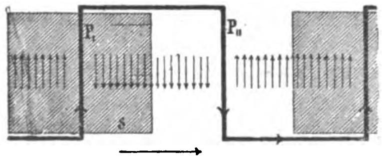

FIGURE 14.

$a_{,}$, $b_{,}$, $c_{,}$, $d_{,}$, of the currents, we find that we may substitute the rotary currents by two distinct sets of rectilinear currents, one of a horizontal, the other of a vertical, direction, We also find that all the vertical currents between a north and south pole are directed upwards when the south pole is to the right of the north pole; and all will flow downwards when the south pole is situated to the left of the north pole—we facing the poles. The horizontal currents, on the contrary, change their directions from pole to pole, and a little consideration will make it clear that they constantly neutralize themselves in their inductions upon the

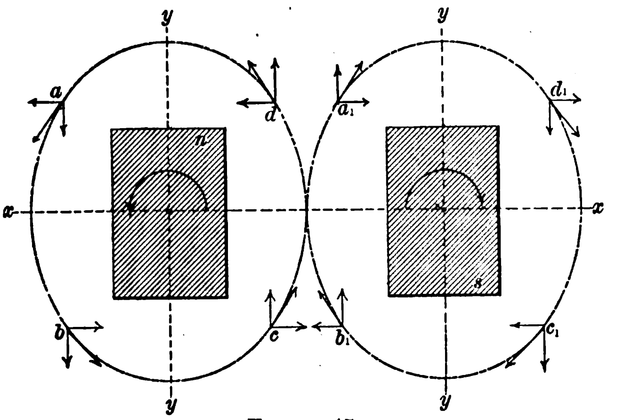

FIGURE 15.

moving element, as well with regard to the parts P as also concerning the parts R. The only currents which concern us, then, in the generation of useful inductions are those of a vertical direction, and these currents are indicated in their proper directions, in figures 11 and 12, by a number of vertical arrows.

In figure 11 the vertical parts, $P_{,}$ $P_{,,}$, are shown as occupying a central position between two succeeding field-magnets. By moving to the right, the part $P_{,}$ recedes from the electrical currents of the south pole on its left side, which are directed downwards, and this, according to the laws of electrical induction, induces in $P_{,}$ an equally directed current (downwards); but simultaneously $P_{,}$ approaches the electrical currents of the north pole on its right side, which are also directed downwards, and this induces in $P_{,}$ a current of contrary direction (upwards). The two induced currents being of opposite direction, and the two groups of electrical currents which induce them being of equal intensity (on account of the assumed central position of $P_{,}$), the inductions neutralize one another. This position of $P_{,}$, and also of $P_{,,}$, in which an analogous process takes place, is therefore a neutral one for $P_{,}$ and $P_{,,}$.

Before examining the inductions of $R_{,}$ and $R_{,,}$ we proceed to the position in figure 12. $P_{,}$ and $P_{,,}$ are passing the centres of the field magnets; $P_{,}$ is receding from the electrical currents on its left, all of which are directed downwards, and it is approaching the electrical currents on its right, all of which are flowing in an upward direction. Both of these groups of currents assist each other to induce a powerful current in $P_{,}$ of a downward direction; and in an analogous manner an upward directed current is induced in $P_{,,}$ at the south pole on the right. $P_{,}$ and $P_{,,}$ were moving from a neutral position into this one of most intense action; they now move on, the inductions diminishing gradually, to the next following neutral position, from which further on the inductions will again increase, though in a contrary direction.

Considering the position of the concentric part $R_{,}$, in figure 12, moving close to the pole-pieces, it will be observed that all the electrical currents between $P_{,}$ and $P_{,,}$ flow away from R′ in a direction at right angles, and this, according to the laws of induction, induces in $R_{,}$ a current of equal direction with the motion of the latter, which corresponds with the direction of the simultaneously induced currents in $P_{,}$ and $P_{,,}$. The same holds true of the induction in $R_{,,}$. If $R_{,,}$ was bent to the left, as in figure 5, the current would then be induced in an opposite direction to the motion of $R_{,,}$, but still in harmony with the currents in $P_{,}$, R, and $P_{,,}$.

By examining the element in different positions, relative to the field-magnets, it will be found that all the parts of an element of the armature are always induced alike. All elements, therefore, which have simultaneously the same relative position to the stationary field-magnets, and which elements are connected into one continuous course, will be traversed by induced currents of uniform direction, and generated in all of the different parts, P and R. Moving the elements gradually along the line of magnets neutral positions alternate with positions of most intense action, and with 16 pairs of field magnets, all of them having open poles, there will be 16 alternations of the currents in all parts of the disc during one turn of the shaft.

It remains yet to be explained why the new arrangement of the magnets with bridge-pieces, F, does not alter the manner and number of inductions as described above. Remembering that now all active south poles are on one side of the armature, and all active north poles on the other side, a glance at figures 13 and 14, representing acting south poles as facing us, will at once show that substantially the directions of the electrical currents are the same as when all poles were open and active. Figure 13, in which the element is in a central position between two acting poles, is again also a neutral position; while figure 14, in which $P_{,}$ is in the centre of an active pole, exhibits one of the positions of most intense action. The number of alternations of the current during one revolution of the disc is the same as before.

When considering the remarkable results obtained with the experimental machine, we find them to be due principally to the lengths, and to the ingenious and economic disposition of the copper conductors in the armature, so that all of the parts are usefully induced. Other important reasons will be found in the most intense magnetic field which is distributed over the entire disc; in the connection at the commutator of the several series of the disc in parallel, and in the total absence of iron in the armature, with its unavoidable coercive resistance, and consequent losses by radiation of heat.

United States patents have been allowed for Bollmann's dynamo, and will be published shortly.

ADDITIONAL DATA CONCERNING THE EXPERIMENTAL MACHINE.

It had 12 (not 16) pairs of field magnets, and they were all active, like G G, figure 1.

The width of the pole-pieces was $3\frac{3}{4}$ inches (95 mm.), and the intervening spaces were $2\frac{1}{8}$ inches (55 mm.), the measurements being taken at the outer circumference.

The magnets were in shunt connection, partly in parallel and partly in series. The weight of all the 24 magnets with windings was 685 lbs. (312 kilos). The total weight of copper in the armature was 66 lbs. (30 kilos), of which the inactive part between the flanges, C, weighed about 13 lbs., leaving, therefore, about 53 lbs. as the weight of the active conductors. The outside diameter of the disc was $23\frac{5}{8}$ inches (60 cm.), and its thickness between the pole-pieces was scant $\frac{1}{2}$ inch (12 mm). The elements were arranged to form four separate series. The total length of all radial parts $P_{,}$ $P_{,,}$, and all concentric parts, $R_{,}$ $R_{,,}$, in each series was 56 feet (17 m.), about one-half being absorbed by the radial, and the other half by the concentric parts. The four series were connected directly with the commutator in parallel. There were constantly two, and sometimes three, of the series in contact with the brushes, two, and sometimes one, being cut out. The internal resistance of the disc (two circuits being in parallel) was 0.002 ohm.

APPLICATION OF ELECTRICITY TO HOROLOGY.

BY CHARLES A. TERRY.

(Concluded from page 171.)

III.

II. SECONDARY ELECTRIC CLOCKS OR DIALS.

In establishing an electric clock system, a series of secondary clocks or dials are electrically connected with a reliable central regulator or time-keeper, which may be either electrically or mechanically operated. The movements of the latter control the dials through the agency of electric impulses which it causes to traverse the connecting conductors. It is pertinent to the subject of secondary electric clocks, therefore, to speak of the devices whereby the actuating impulses are transmitted. One method is to oscillate a solenoid attached to the pendulum of the regulator, over the poles of a permanent magnet, as proposed by Mr. Wheatstone, and later by Mr. J. A. Stroh. The alternating electric impulses thus induced, actuate an astatic system of magnetic needles applied to each secondary clock. These are kept in continued rotation by the impulses, and their motion is communicated through their respective time-trains to the hands of the secondary clocks. The electric circuit is thus never interrupted in such a system. The impulses derived in this manner are of sufficient strength to actuate a very heavy pendulum, if rightly applied. The period of the pendulum must, of course, be very nearly the same as that of the impulses, or else the one a multiple of the other. An experiment made by Prof. Farmer about the year 1871, furnishes a striking illustration of the effect which may be, in this manner, produced by very weak currents. At that time two-second time signals or beats were transmitted from the Cambridge Observatory to a watchmaker's store in Boston. Prof. Farmer employed the receiving instrument as a relay for controlling the connections of a circuit through a pendulum bobbin of the character employed by Bain, Ritchie and others. (See figure 1, p. 91.) The relay served to complete a circuit through the bobbin or solenoid each two seconds, and an attractive force was thus periodically established between the solenoid and a permanent magnet over which it swung. With a battery of any considerable size it would, of course, be expected that the pendulum would at once respond. The battery which Prof. Farmer used consisted of four percussion caps, serving both as battery-cells and as copper plates, in each of which was placed a drop of solution of copper-sulphate and a zinc wire about $\frac{1}{16}$ of an inch in diameter. It required but a very few minutes for the impulses of this battery to establish the regular vibration of the pendulum, which weighed, say five or six pounds. The liability of other induced currents to be present upon the conductors, however, is a serious obstacle, which practically prevents the successful operation of a system organized upon the induced current principle. A better plan is to obtain the impulses by making and breaking the connections of a strong battery through the circuit leading to the secondary movements, as proposed, for instance, by Mr. Ritchie in 1872, and by these stronger impulses to maintain the movements of secondary pendulums which drive the clock movements. Both these methods, however, are applicable rather to synchronizing than to actuating pendulums. The plan usually adopted for operating the secondary movements is to obtain the periodic impulses by opening and closing the circuit of a battery by the movements of the prime regulator, and to drive each secondary movement by the vibrations of a pawl or an anchor driven to and fro by an electro-magnet included in the circuit. The impulses for driving the secondary clocks are usually transmitted each minute, second or half-second. It is customary to actuate the smaller dials every minute, while it is necessary, in operating the heavier movements, such as gallery dials and tower clocks, that the impulses should be more frequent; otherwise, the work to be performed by a single impulse would be excessive.

The more serious difficulties encountered in constructing circuit-closers for transmitting the impulses, arise from the destruction of the contact-points by the static discharge of the line and the liability of false contacts being made. To obviate this, attempts have been made to exclude oxygen from the points. William H. Hatcher, of England, in 1847, patented a circuit-closer consisting of an hermetically sealed glass vacuum tube, partly filled with mercury. Two platinum wires sealed into the tube constitute the terminals of the electric circuit. The tube, when rocked upon its transverse axis by the operation of the regulator, causes the mercury to complete the circuit periodically. An objection to the use of mercury as a circuit closing medium has always been found in its tendency towards oxidation or sublimation. By means of the vacuum tube Hatcher expected to overcome this difficulty. George S. Leclanché, in 1871, proposed a circuit-closer of this character, consisting of an hermetically closed glass tube divided into two compartments by a transverse partition, but communicating with each other through a narrow opening placed eccentrically. Each compartment is half filled with mercury, and the rotation of the tube carries the opening beneath the surfaces of the mercury, and thus places the mercury in the compartments in connection through the opening. In 1876 Mr. Davis, of Cleveland, patented a circuit-closer operating to complete the connections through metallic points, which the movements of the pendulum cause to dip into mercury submerged in kerosene or coal-oil. Charles Shepherd, in 1849, proposed to suspend a weight inside a sealed glass tube attached to the pendulum, the weight making alternate contact with platinum points introduced through the sides of the tube. The air was to be exhausted from the tube, or else to be replaced by hydrogen, and thus oxidation prevented. Experience has shown that the more desirable, as well as the more philosophical, plan is to remove the cause of the discharge, and thus of the oxidation at the points, rather than the means, and the open-air mechanical forms of circuit-closers, in connection with the various devices for preventing disruptive discharges, have come into more general use. It will not be expedient here to refer in detail to the numerous different forms of circuit-closers which have appeared at various times, further than to state that for the most part they have been constructed either upon the principle of revolving contacts passing beneath a contact surface, or a sliding contact-arm moved by a pendulum to and fro across contact-points, as illustrated in a patent of S. A. Kennedy, in 1867, or else by the direct impingement of one contact-point against another. Bain, it will be remembered, proposed to employ a non-conducting disc containing a series of metallic studs, which passed beneath a circuit-closing spring. The sliding or rubbing made in this manner is usually objectionable, for the reason that the presence of a particle of dust or oxide, or an uneveness in the contact surface, renders a succession of contacts very liable to occur, and a series of impulses to be transmitted instead of a single one. The direct impingement of one contact against another is usually considered the best plan to adopt. This may be accomplished by the impact of a contact-point upon the pendulum of the regulator against yielding arms extending into its path, as shown, for instance, in the U. S. patent of F. J. Ritchie, No. 143,847, of 1873, or by a contact-spring periodically pressed by the movements of the regulator against a stationary contact-arm or a second yielding contact spring. It has also been proposed to complete the circuit by the contact of the crutch-pin with one side of the aperture in the pendulum rod in which it works. The methods illustrated in figures 2 and 3 (pp. 169 and 170) have been found very excellent. It will be noticed that the circuits are, in these instances, closed through the impulse pawls, the regulators being themselves electrically actuated.

Digitized by Google

However reliable the necessarily delicate contacts may be in other respects, they will become useless if exposed to repeated disruptive discharges which occur at the interruption of the circuit. Such discharges are due in part to the static capacity of the line wire, but to a great extent result from the inductive capacities of the electro-magnets in circuit. The occurrence of such discharges at the contact-points is to a great extent prevented, either by bridging the coils of the electro-magnets by resistance circuits or by substituting a second circuit for the circuit through the contact-points. In practice both methods are often resorted to. It is now customary, in certain clock systems, to place coils of fine wire in permanent circuits around the magnets, as shown in connection with the diagram, figure 3, of the primary clock. Among the best methods which have been suggested for substituting subsidiary circuits at the circuit-closing points, and thus affording a path through which the static discharges may take place, are those proposed by Mr. H. L. Bailey, by Mr. Himmer and by Mr. C. L. Clarke. According to Mr. Bailey's plan, a non-inductive shunt-circuit is completed after the actuating battery connections are formed, and it remains so completed a sufficient time after the separation of the delicate contact-points to allow the discharge to take place. The plan proposed by Mr. Himmer is to first complete the circuit-connections of the battery through an artificial resistance circuit, and to immediately afterwards temporarily substitute the clock circuit for the resistance circuit. The clock circuit remains closed, to the exclusion of the resistance circuit, a sufficient time to actuate the clocks. The resistance circuit is then again closed, and clock circuit opened, and finally the resistance circuit is again opened. The Clarke method is to close, by the operation of the delicate contact-points, a circuit through an electro-magnet adapted to operate heavier and stronger contacts, which serve to transmit the actuating current through the clocks. After all the instruments have operated the circuit is interrupted at a third contact point, which is specially constructed to withstand the detrimental effects of the disruptive discharges.

The secondary movements themselves vary principally in the method of applying the pawls and anchors to the driving-wheels of the time-trains. It is essential that the driving-wheels should not be liable to accidental displacement, and should not be advanced more than one tooth at each vibration of the anchor or stroke of the pawl, by reason of any unwonted force, such as might be occasioned by an increase in battery strength; on the other hand, there never should be a failure of the wheel to advance its regular distance. The latter end is more easily attained than the former, which has called forth various systems of locking pawls. A simple vibrating anchor, having driving-pallets, operates, in many instances, very successfully, though the difficulty of locking the movement when the hands are at rest is an objection. Messrs. Edmands and Hamblet, in 1868, described a driving anchor, having peculiarly formed driving-pallets, in connection with two locking pawls, one engaging a ratchet-wheel secured to the driving-wheel arbor, when the anchor is at the left hand, and the other when it is at the right. Mr. A. S. Crane, of Newark, in 1883, planned a somewhat novel relation between the angles of the teeth and the driving pallets of the anchor, which proved to be advantageous. At about the same time he modified the well-known metronome escapement for the purpose of propelling the wheels, and this proves also a very effective device for actuating the secondary movements. One other movement, possessing the double merit of being ingenious and useful, should be mentioned. It is that patented by Mr. A. W. Gray in 1883. It consists of a pawl pivoted in an armature-lever in such manner that it is first carried by the latter in a radial direction towards the centre of the driving-wheel into engagement with the teeth of the wheel. An arm or right-angled extension of the pawl then strikes a fixed stop, causing the end of the pawl between the teeth to move in a tangential direction, with reference to the wheel, which is thus advanced. The return movement of the lever withdraws the pawl, which, upon the next forward movement, enters between the succeeding teeth and repeats the operation.

Mr. L. H. Spellier, in 1882, patented a noiseless secondary clock. He makes use of a circular armature or range of armatures carried upon a star wheel, which is advanced step by step, partly by the action of an electro-magnet, and partly by the operation of a weighted lever. The electro-magnet advances the wheel until two armatures confront its poles, and when in this position a small roller upon the weighted lever presses against the face of one of the teeth near its apex. Upon the interruption of the circuit, the electro-magnet being demagnetized, the lever and roller advance the wheel still further.

III. SYNCHRONOUS PENDULUMS.

One method of maintaining several independently actuated clocks in unison with each other, is to cause their pendulums to vibrate synchronously. It is necessary that the normal periods of the pendulums should either be approximately equal or multiples of each other and that there should be some standard controller or regulating pendulum. A very slight force, if rightly applied, is sufficient to govern the movements of a pendulum tending to vibrate in periods approximately the same as the recurrence of the force. The subsidiary pendulums may be constructed to vibrate in slightly shorter periods than the regulating pendulum and be caused to move slowly by some retarding influence controlled by the latter, or they may be adjusted to vibrate in as nearly as possible the same periods, and an accelerating or retarding force applied thereto accordingly as they lag behind or gain upon the regulator. In 1869 H. W. Cook described in an English patent a clock-system regulated upon the principle of retardation. The clocks were adjusted to gain, and the pendulums were caught at the ends of their beats by an electro-magnet and released at the proper instant by the controlling clock which operated to break the circuit. Giovanni Casselli, of Switzerland, in 1863, also obtained synchronism of pendulums for the purposes of autographic telegraphy, in essentially the same manner. The method more frequently employed, however, is that of either retardation or acceleration as the case may require. This was accomplished by some of the earlier inventors of electric clocks, and one method was fully described by Bain. Other adaptations were made by Wilson, Ritchie and Kennedy, and later by Mr. Bailey and Mr. Himmer. The earlier plan was to cause a permanent magnet to swing into and out of a stationary solenoid at each vibration of the regulating pendulum. Should the vibrating magnet be slightly behind, at the instant the current traversed the solenoid, the tendency would be to accelerate its motion. On the other hand, should it be in advance its tendency is to retard. It is now preferred to place electro-magnets at the limits of the pendulums' vibration and to cause them to act upon soft iron armatures carried upon the pendulums. Mr. Bailey's invention consisted essentially in organizing a system of circuits which prevented the current from being transmitted through the regulating magnets so long as the pendulums beat in unison. Any acceleration or retardation on the part of any pendulum, caused the magnet of that particular pendulum to be brought into circuit, and the attraction which it exerted upon the armature to retard or hasten its movement accordingly. Mr. Himmer's plan was to send alternating currents through the regulating magnet so that any tendency of the magnets to become permanently magnetized were avoided.

IV. CORRECTING DEVICES.

One of the methods proposed for correcting the position of the minute-hand of a clock, which has already been referred to in connection with the Barwise and Bain inven-

Digitized by Google

tions of 1841, is to grasp the hand at the proper moment by two pivoted clips, which move it either backward or forward a slight distance as the case may require. The means for carrying out this method has been variously modified. George Lund, of London, about the year 1877, invented certain improvements relating especially to the means for actuating the arms or clips. Mr. Hamblet, in 1882, proposed to operate one of the clips by means of a rack-bar attached to an armature lever and engaging a pinion upon the arbor of that clip. The second clip is geared to and thus moves with the first. This class of device was widely advertised and extensively introduced in England. The clocks employed at the stations of the elevated railways of New York, are equipped with synchronizing devices, furnished by the Standard Time Co., and constructed upon this general plan. Although the clocks are thus equipped, we understand that in practice they are not considered necessary, for the time kept by the clocks is sufficiently accurate without resorting to them.

Another method of correcting the hand is to construct the hand itself of iron or steel, and place an electro-magnet behind the dial at the point where it is desired to set the hand. An electric impulse transmitted through the magnet at the proper instant serves to advance the hand or move it backward. Such a device was invented as early as 1847 by Mr. W. H. Hatcher, who has been before referred to.

The next class of hand correcting devices to be noticed are those in which an arm or cam is attached to the arbor of the minute hand, and this is turned back or forward by a lever operated by an electro-magnet. The principle is very simple and when once suggested admitted of improvement only in minor details of construction. In 1853 it was suggested in a provisional patent granted to E. Dobell, of Hastings, England, that the minute hand of a clock movement be freed from the train at the proper moment by an electro-magnet and set in position by a wedge inserted in a recess formed in a disc upon the minute-hand arbor. Mr. Himmer and others employ a heart-shaped cam, which is capable of turning the arbor one-half a revolution in either direction and thus correcting very great errors. Mr. A. A. Knudson, of Brooklyn, in 1882, patented a combined printing-telegraph instrument and clock in which the setting device consisted of a straight bar attached to the arbor and engaged by a forked arm under the control of an electro-magnet. The forked arm normally stands out of the range of the armature lever of the electro-magnet, but is thrown into the path by the operation of the clock. M. Breguet, in 1857, patented in France a clock mechanism wherein an independent train was employed for synchronizing the hands. This train was released at a predetermined time, and when so released set the hands. R. W. Willson, of New Haven, in 1883, patented a somewhat similar organization containing the additional feature of means for automatically arresting the movement of the synchronizing mechanism when the hands have been set, irrespective of the duration of the current setting the mechanism in operation.

An English patent granted to Wm. S. Harrison in 1868, contained a description of an apparatus for setting the hour, minute and second hands either backward or forward to the exact time. During the five seconds preceding the time which the clocks are to be set to indicate, a cam on the minute-wheel of the regulator completes the circuit through an electro-magnet in each subsidiary clock. These detach the hands from the driving mechanism and unlock a special movement. The minute-hand is set by a pin upon its wheel engaging a lever operated by the special movement and the second wheel is set by a lever and a heart-shaped cam.

It will be noticed that the synchronizing devices are brought into requisition not more frequently at the most than once an hour and usually only once in 12 hours. This fact has given rise to the devising of means for permitting the line wires to be employed at other times for other purposes. The French patent of M. Breguet of 1857, describes a hand-setting apparatus consisting of two revolving discs, each containing a projecting pin which engages upon the corresponding side an arm projecting radially from the minute-hand arbor. If the hand be too fast one pin sets it back and if too slow the other pin sets it forward. The discs revolve a sufficient distance to bring the pins out of the path of the arm immediately after the setting is accomplished. The discs are driven by an independent train released by an electro-magnet. Mr. Dobell, whose invention has been already referred to, proposed in his provisional patent to use the wires leading to the setting device at other times for general telegraphic purposes, and to automatically connect the setting devices in circuit at the proper periods. Mr. J. F. Kettell, of Worcester, in 1883, patented certain improvements in apparatus for setting in operation the independent train for operating the setting device, and connecting and disconnecting the apparatus from circuit when the synchronizing apparatus was not released, so that the line might be employed for other purposes such, for instance, as telegraphy.

We have now considered the more important methods of employing electricity for assisting in indicating time. Certain other branches of the general topic, such as the transmission of time signals, the releasing of time-balls and the operation of striking mechanism, it has not been the purpose of this article to discuss.

"ON THE CHANGES PRODUCED BY MAGNETIZATION IN THE LENGTH OF RODS OF IRON, STEEL AND NICKEL."[1]

BY SHELFORD BIDWELL, M.A., LL.B.

THE earliest systematic experiments on the effects produced by magnetization upon the length of iron and steel bars are those of Joule, an account of which is published in the *Phil. Mag.* of 1847. Joule's experiments have many times been repeated, and his general results confirmed. In particular, Prof. A. M. Mayer carried out a series of very careful observations with apparatus of elaborate construction and great delicacy. The conclusions at which he arrived were in accord with those of Joule, so far as regards iron; in the case of steel there was some apparent discrepancy, which, however, might to a great extent be accounted for by differences in the quality of the metal used, and in the manner of conducting the experiments. In 1882 Prof. Barrett published in *Nature* an account of some experiments which he had made, not only on iron but also on bars of nickel and cobalt, with the view of ascertaining the effect of magnetization upon their length.

The knowledge on the subject up to the present time may be summarized as follows :—

1. Magnetization causes in iron bars an elongation, the amount of which varies up to a certain point as the square of the magnetizing force. When the saturation point is approached the elongation is less than this law would require. The effect is greater in proportion to the softness of the metal.

2. When a rod or wire of iron is stretched by a weight, the elongating effect of magnetization is diminished; and if the ratio of the weight to the section of the wire exceeds a certain limit, magnetization causes retraction instead of elongation.

3. Soft steel behaves like iron, but the elongation for a given magnetizing force is smaller (Joule). Hard steel is slightly elongated, both when the magnetizing current is made and when it is interrupted, provided that the strength of the successive currents is gradually increased (Joule). The first application of the magnetizing force causes elongation of a steel bar if it is tempered blue, and retraction if it is tempered yellow : subsequent applications of the *same* external magnetizing force cause temporary retraction,

1. Abstract of paper read at the Meeting of the Royal Society, April 23d, 1885.

Digitized by Google

whether the temper of the steel is blue or yellow (Mayer).

4. The length of a nickel bar is diminished by magnetization, the maximum retraction being twice as great as the maximum elongation of iron (Barrett).

In order that the results of Joule and Mayer might be comparable with those obtained by the author, he made an attempt to estimate the magnetizing forces with which they worked. From data contained in their paper, it was calculated that the strongest magnetizing force used by Joule was about 126 units, while the strongest used by Mayer did not on the highest probable estimate exceed 118 units. In the author's experiments the magnetizing force was carried up to about 312 units. The metal rods, too were much smaller than any which had been before used for the purpose, ranging in diameter from 1·40 to 6·25 mm. Their length was in every case 100 mm., and the apparatus was capable of measuring with tolerable certainty an elongation or retraction equal to a ten-millionth part of this length.

By using thinner iron rods and greater magnetizing forces than those previously employed, the following curious and interesting fact was established. If the magnetization be carried beyond a certain critical point, the consequent elongation, instead of remaining stationary at a maximum, becomes diminished, the diminution increasing with the magnetizing force. If the force is sufficiently increased, a point is arrived at where the original length of the rod is totally unaffected by magnetization; and if the magnetization be carried still further, the original length of the rod will be reduced. It also appeared that the position of the critical point in steel depended in a very remarkable manner upon the hardness or temper of the metal; considerable light is thus thrown on the apparently anomalous results obtained by Joule and by Mayer. Further experiments disclosed strong reason for believing that the value of the critical magnetizing force in a thin iron rod was greatly reduced by stretching; this would explain the fact that Joule obtained opposite effects with stretched and unstretched wires.

By ascertaining the relative values of the temporary moments induced by gradually increasing external magnetizing forces, an attempt was made to connect the point of maximum elongation with a definite phase of the magnetization of the several rods in which the elongation had been observed.

Though more experiments must be made before it is possible to generalize from them with perfect safety, the results so far obtained by the author indicate the laws given below. The elongations and magnetizations referred to are temporary only; before the beginning of an experiment the rod was permanently magnetized by passing through the magnetizing coil a current equal to the strongest subsequently used. In iron the greatest elongation due to permanent magnetization was generally found to be about one-third of the total elongation, while in nickel the permanent retraction amounted only to about one twenty-fifth part of the whole.

I. IRON.

1. The length of an iron rod is increased by magnetization up to a certain critical value of the magnetizing force, when a maximum elongation is reached.

2. If the critical value of the magnetizing force is exceeded, the elongation is diminished until with a sufficiently powerful magnetizing force the original length of the rod is unaffected, and if the force is still further increased the the rod undergoes retraction. Shortly after the critical point is passed, the elongation diminishes in proportion as the magnetizing force increases. The greatest actual retraction hitherto observed was equal to about half the maximum elongation, but there was no indication of a limit, and a stronger magnetizing force would have produced further retraction.

3. The value of the external magnetizing force corresponding to maximum elongation is for a given rod, approximately equal to twice its value at the "turning point."

Definition.—The turning point in the magnetization of an iron bar is reached when the temporary moment begins to increase less rapidly than the external magnetizing force.

4. The external force corresponding to the point of maximum elongation increases (when the quality of the iron is the same) with the diameter of the rod. So also does its value at the turning point.

5. The amount of the maximum elongation appears to vary inversely as the square root of the diameter of the rod, when the quality of the iron is the same.

6. The turning point, and therefore presumably the point of maximum elongation, occurs with a smaller magnetizing force when the rod is stretched than when it is unstretched.

II. STEEL.

7. In soft steel magnetization produces elongation, which, as in the case of iron, increases up to a certain value of the magnetizing force, and afterwards diminishes. The maximum elongation is less than in iron, and the rate of diminution after the maximum is passed is also less.

8. The critical value of the magnetizing force for a steel rod diminishes with increasing hardness up to a certain point, corresponding to a yellow temper; after which it increases, and with very hard steel becomes very high. There is therefore a critical degree of hardness for which the critical magnetizing force is a minimum; in steel of a yellow temper the value of the critical magnetizing force is lower than in steel, which is either softer or harder.

9. In soft steel a strong magnetizing force subsequently diminished may cause a greater temporary elongation than the diminished force is capable of producing if applied in the first place.

10. A temporary elongation when once produced in soft steel may be maintained by a magnetizing force which is itself too small to originate any perceptible elongation.

III. NICKEL.

11. Nickel continues to retract with magnetizing forces far exceeding those which produce the maximum elongation of iron. The greatest observed retraction of nickel is more than three times the maximum observed elongation of iron, and the limit has not yet been reached.

12. A nickel wire stretched by a weight undergoes retraction when magnetized.

THE MISSING CABLE STEAMER.

The new steamer Magneta, recently constructed especially for the laying and repairing of cables, is now supposed to have been lost with all on board. She left the Thames for Singapore early in March, and has not been heard from since leaving the Channel. One of her boats was seen 200 miles off Cape Finisterre, on the northwest coast of Spain. It appeared to have been properly lowered, but there was no apparent evidence of its having been occupied. She was a sister vessel to the Electra, and both were constructed upon the most approved plans, and supposed to be as thoroughly capable of weathering any storm as it is possible to build a ship. The fact that her boilers were of steel brings up the question as to the adaptability of this material for such purposes. The failure of a new steel boiler, under a hydraulic pressure of 240 pounds pressure, has led to an investigation, under the direction of Lloyd's Register, of the process of manipulation of the plates. Mr. Parker, who conducted this examination, is of the opinion that the plates are injured by unequal heating.

In commenting upon this important question, the *English Mechanic* says that there is at least ground for suspicion that not only the Magneta, but other missing steamers have foundered in consequence of boiler explosions.

ON THE RESISTANCE OF PURE COPPER WIRE.

BY GEO. B. PRESCOTT, JR.

SEVERAL years ago Mr. Sidney B. Paine prepared a table giving the electrical resistances of pure copper wires drawn to the Brown & Sharpe, or so-called American gauge, which proved to be of considerable practical convenience to electricians generally, and especially to those engaged in electric lighting. So far as I am aware, it is the only one of the kind in common use in the United States to-day. The basis for the calculations in this table was that a pure copper wire, one foot long and one mil diameter, has 10.8 ohms resistance at 75° F., or, to express it more conveniently, $R_{ft.} d^2 = 10.8$. As Mr. Paine omitted to state how or where he procured this standard, it is to be presumed that he determined it experimentally. According to Dr. Matthiessen,[1] the resistance of one English mile (5,280 feet) of chemically pure copper wire $\frac{1}{16}$ inch (62.5 mils) in diameter, at the temperature of 15.5° C. (59.9 F.), is 13.59 ohms, which is equivalent to $R_{ft.} d^2 = 10.381$. This value was arrived at by means of an exhaustive series of experiments on samples of copper procured from various parts of the world, and has been generally referred to as a standard. I know of no other authoritative determination of the specific resistance of copper, nor have I ever heard any doubts expressed as to the correctness of Matthiessen's figure, excepting to the effect that, if anything, it appears to be a trifle *too high*. I have myself tested specimens of copper wire having, on Matthiessen's basis, a conductivity of a fraction over 100 per cent., and have thought the discrepancy might be due to the superior methods of working and drawing copper now in vogue. It will be seen from the figures given above that there is a difference of about four per cent. between Matthiessen's and Paine's determinations; and as the latter's figure is even *higher* than Matthiessen's, it is extremely improbable that it can be correct, and there certainly appears to be no reason for accepting it. Assuming Matthiessen's figure, Paine's table is right for wire at the temperature of 94° F., which is too high, however, to be of much practical utility.

The following table is calculated on the basis of Matthiessen's standard, and sufficiently explains itself:

WESTON LABORATORY, NEWARK, N. J.,

THE RAILWAY SIGNAL DECISION.

BY JOSEPH P. LIVERMORE.

THE Supreme Court has recently rendered a decision which may be of considerable interest to electrical inventors and owners of patents on electrical apparatus.

But comparatively few cases on electrical patents have recently come before the Supreme Court, and it is interesting to learn what will be its treatment of such cases. If the decision referred to is to be followed, electrical patents will be of but little value.

The subject-matter of the case in question, and the relation of the patented apparatus to that used by the defendant is clearly shown in the following diagrams. Figure 1 represents the apparatus on which complainant's patent was granted.

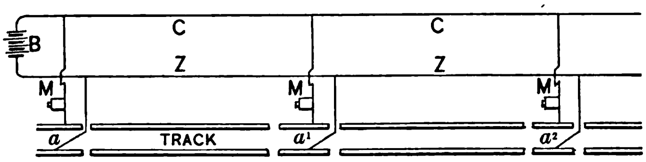

FIGURE 1.

The object of the invention is to operate a number of railway signals on what is known as the "block-system" from a single battery, instead of using a separate battery for each block of the track and its signals, as had been previously practiced. To accomplish this, the inventor extends from the battery, B, two main conductors, C and Z, and at each of the block sections or points where the signals are to be operated, these conductors are connected with normally open branches as shown, including electro-magnets, M, which operate or control the signals. The branches contain circuit-closers operated by the train, so that when a train passes a given one, the branch is closed automatically, the electro-magnet energized, and the signal or signals controlled by it are operated. The circuit-closer shown and described in the patent consists of a pair of opposite rails insulated from one another and from the rest of the track and connected with the terminals of the branch-circuit, so that when the wheels and axles of the train pass over these rails they complete the branch-circuit and thus cause the magnet to be energized. Figure 2 represents the

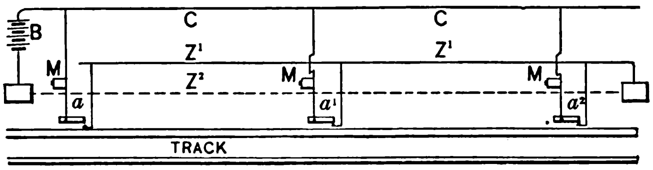

FIGURE 2.

defendant's apparatus, the same letters being used to indicate the corresponding parts. It differs from the complainant's apparatus in that instead of using a wholly metallic circuit one pole of the battery is grounded, and a wire, Z^1, open or insulated near the battery, extends along parallel with the main wire, C, and is grounded at the end of the series of signals remote from the battery. The signal magnets, M, are in normally open branches between the wires C and Z^1, and it will be seen that the wire Z^1 with the earth-return, represented at Z^2, forms a conductor from any of the branch-circuits to one pole of the battery, thus corresponding in function to the main wire Z of figure 1. Another difference between the two devices is that the circuit-closers A A^1, figure 2, used by defendant were of a peculiar construction invented by him, but belonging to the general class that are operated by the action of the wheels of the trains on one end of a lever or treadle. It may be stated here, although not alluded to especially in the decision, that both kinds of circuit-closers were known in connection with railway signal apparatus long before the patent, although defendant's circuit-closer, as before stated, contains some novel features in the minor details of construction. With regard to the circuit-closers the patentee makes the following statement in his specification :

> I do not desire to confine myself to the use of any particular form of visual or audible signals, nor to the particular devices herein described for closing the electric circuit at points from which a signal is to be operated. Instead of the circuit being closed automatically by the train itself, it may be closed by a signalman by means of a key or switch, or otherwise.

His first claim is as follows :

> The battery B in combination with the positive and negative conductors C and Z, two or more electro-magnets M, M^1, M^2 for actuating or causing to be actuated visual or audible signals, and two or more circuit-closers, a, a^1, a^2, placed at intervals along the line of a railroad, substantially as and for the purpose specified.

The Court decided that the apparatus, shown in figure 2, does not infringe the above claim in view of the differences in construction and arrangement that have already been mentioned in describing figure 2, and which were considered by the Court to be material and substantial. The decision admits the validity of the patent and of the claim above cited, but asserts that either one of the differences above referred to namely, the difference in the circuit-closers, or the difference in the main circuits, alone is sufficient to avoid the patent or remove defendant's apparatus from the scope of the claim.

In referring to the difference in the circuit-closers the Court first states that the patent is merely for a new combination of old well-known devices, the separate elements of which were not claimed by the patentee, and that consequently "to constitute identity of invention and therefore infringement not only must the result attained be the same, but the elements combined in both cases must be the same and combined in the same way so that each element shall perform the same function ; provided, however, that the differences alleged are not merely colorable according to the rule forbidding the use of known equivalents."

The Court then decides that the insulated sections of the rails as circuit-closers constitute an essential element in the combination described in the patent, and that the difference between them and the lever or treadle-circuit-closer is material. In referring to the phrase above quoted from the patent that "the circuit may be closed by a signalman by means of a key or switch or otherwise," the Court states that the only alternatives proposed have reference not to a substitute for the insulated track-sections "but merely to another mode of using them in closing the circuit." It is interesting to attempt to picture what the Court had in mind in making this statement ; or to try to graphically represent the Court's conception of a key or switch for closing the branch-circuits in figure 1, that would still involve the rail sections as essential to the operation ; or to explain how the Court thought the *rails* were to be used in closing the branch circuits by a *key* or *switch*. The language of the decision, after referring to the fact that the circuit-closers A, A^1, A^2, are expressly named as a part of the combination, is as follows : "The use of insulated sections of the railroad track thus repeatedly appears in every part of the specifications as an unchangeable and characteristic feature of the invention, and there is nothing in the state of the art at that date, as disclosed in the evidence, to show that the patentee would have been justified in applying, or that, if he had applied, an application would have been sanctioned by a grant of a patent, for a combination as large and undefined as that now claimed by implication and construction, so as to cover every form of a circuit-closer then known or thereafter invented ; for that employed by the defendants as part of the Hall system was not only not known and in use at the

Digitized by Google

date of the patent, but was a device invented by Hall himself or one by Snow, for which the latter obtained a patent dated October 21, 1873. It dispenses altogether with the use of insulated sections of the track, and employs instead a separate instrument placed near the track, and worked by means of a lever connected with the track, so that the wheels of locomotives and cars passing on the track depress the outer end, the lever being raised again and held up after the train has passed by means of a spring, which holds it in place."

It has been tacitly acknowledged in the decision, or at any rate no evidence is cited to the contrary, that the result of operating a number of signals from a single battery was novel, and no doubt is raised as to the validity of the combination claim; Why then should the inventor be restricted to the precise construction of *each element* of the new combination? There was no more novelty in using the rails for the circuit-closer than in using any other form of circuit-closer known at that time in combination with the other elements, and there is no intimation that the rail circuit-closer produced any different effect on the other elements of the combination from what would be produced by any other circuit-closer then known, as in point of fact it did not. If the principle holds that a claim containing as an element of combination "a circuit-closer" does not cover every form of circuit-closer that is suitable for performing the same function in the combination, then an inventor in order to afford himself even a moderate chance of protection for a new combination, will be obliged to take a separate patent to cover each and every form at that time known of each element of his combination in connection with the other elements. In other words suppose there were a hundred or a thousand different varieties of circuit-closers, to be operated automatically by passing trains, in existence at the time he made his invention, he would have to take first a hundred or a thousand different patents each one illustrating and claiming a different one of the said circuit-closers in combination with his other elements B, C, Z and M; and following the doctrine of the Court, it would be just as reasonable to take the elements C and Z, or his line-wires, and take a separate patent for every different way in which they may be supported and insulated, and then take his element B and run through all the different batteries that are known to mankind; for no reason is given or can be suggested why the invention should be limited to the precise construction of the circuit-closer, any more than to the precise construction of each and every other element of the combination, except possibly that the patentee, probably believing that railway track circuit-closers were somewhat less known to the public than batteries and line-wires, took a little more pains in explaining the construction of one which he believed would operate satisfactorily, it being fair to assume that if he had indicated his circuit-closer by a conventional diagram just as he did his battery the Court would not have limited him with regard to his circuit-closer any more than it did with regard to the battery. The patentee who, as an examination of the evidence shows, had had considerable experience in railway signals and found that grounded circuits did not always operate satisfactorily, was also unfortunate enough to give the public the benefit of his experience by stating that the conductors C and Z should be insulated from the ground and from each other. In view of this statement the Court also decides that defendant by using the ground as a part of his circuit with the different arrangement previously referred to, did not use the conductors C and Z of the patent and consequently did not infringe. On this point the defendant introduced expert testimony to show that his part wire and part ground circuit was superior to the wholly wire circuit, because the different circuits completed by closing the different branches are all of the same length or resistance—including the conductor C, up to the branch in question and then the conductor Z^1 to the remote end of the line, and the ground, so that if the conductors C and Z^1 were of equal conductivity it would make no difference which branch were closed, the total length of C and Z, traversed by the current being the same in each case. On this point it may be said that in either construction shown in the above diagrams, sufficient battery would have to be used to traverse the entire line, and of course the nearer branches in figure 1 would form circuits of less resistance than the more remote ones, but the patentee provided for this by stating that their resistance could and should be adjusted so as to be equal or as nearly equal as possible. Of course this might be done in a wholly metallic circuit by making the portion of the circuit, represented by the dotted line Z^2 of figure 2, a wire forming a continuation of the wire Z^1 connected with the opposite pole of the battery, from that connected with the wire C; but any electrician would see at a glance that this would require three wires and would have no advantage over the method of introducing resistance into the branches nearer the battery, equal to that of the main-lines C and Z beyond the said branches; and that really nothing is gained by using the grounded circuit of figure 2 except what is in any case gained (or it may be lost) by using a ground return instead of a wholly metallic circuit. The Court however decided to the contrary that there was sufficient difference between the circuits employed in figures 1 and 2 to bring the latter out of the scope of the patent granted on the former even if in all other particulars the apparatus were the same. It would follow logically that if the patentee had been so unfortunate as to state that he preferred to use a gravity battery and did not mention any other kind of a battery, and defendant had used for instance a Grove or Leclanché battery, that would also have been sufficient to avoid the patent; and applying the principle that defendant's circuit-closer was a new one not precisely the same as any in existence at the time of the granting of the patent, and consequently not a known equivalent nor an infringement of the same, any inventor may, by devising a new finger-key, avail himself of all the various patents on multiplex telegraphy which have happened to show or mention the ordinary finger-key as governing their operation; or by slightly changing the ingredients of a carbon for an electric lamp, he may avail himself of all the patented inventions on electric lamp regulators which have happened to show or mention the ordinary carbons as used for producing the light.

It is probable that the Supreme Court did not get any understanding at all of the electrical relations of the different devices; and because a pair of rails spiked upon sleepers and a railroad train running or standing upon them appear to be very different mechanically from two small springs pressed together to complete an electric circuit, they came to the conclusion that one was not the mechanical equivalent of the other, although it is probable that the average electrician would fail to discover or even think of any difference at all existing between the two devices, electrically considered. It is to be hoped that the Supreme Court will come to appreciate the difference between mechanical and electrical relations in treating patents relating to electrical inventions, as otherwise such patents will be wholly and absolutely worthless; they are nearly all for new combinations of old elements, and the elements employed in electrical apparatus are exceedingly few; electro-magnets, conductors, insulators, and devices for breaking and closing circuits covering nearly the whole ground. But the different combinations and the variety of results produced from these simple devices is almost unlimited, and the forms which these simple devices assume in their different relations is also practically unlimited, so that if, as indicated by the above decision, an inventor were limited to the precise form of each element which he happened to show for the purpose of illustrating his invention in his patent, the difficulty would be not to avoid infringing the patent but to infringe it.

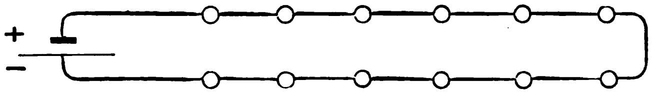
THE DISTRIBUTION OF ELECTRICITY.[1]

In the last lecture we were engaged in preparing the way, as it were, for considering in detail the different schemes which have been proposed for laying the mains from a central station; and the laws which we established in that lecture are applicable not only to a large central station, but even to private installations. I pointed out that there were three different reasons why we cannot seek for economy by diminishing the size of our mains very much: the first is that it is an actual waste of money in consequence of the energy which must be used up to heat those mains; in the second place, when we diminish the size of our mains the heating being increased may cause serious inconvenience in several different ways; and, in the third place, when we have thin conductors, the fall of potential as you go away from the source of electricity is very much increased. I dealt pretty fully with the first two points, the waste of energy in the conductors—a consideration of which leads us to the consideration of the economical size of conductors to use—and, secondly, the heating of conductors. Now let me insist once more on what I spoke of with regard to the economical size of conductors. We must in all our plans for laying mains determine the economical size of conductors by Sir Wm. Thomson's law, and nothing must allow us to deviate from that size of conductor. When we have really accepted this fact we have done a great deal. Very few large stations have been designed on this correct principle. I may mention, for instance, that in the central station in New York there is, as Dr. Fleming informs us, 52 per cent. h. p. wasted between the cylinders of the steam engine and the lamps. Some people have been tempted to depart from the law of the economical size in order to get over the difficulties of the fall of potential, but, as I said last night, these difficulties in regard to the fall of potential must be met as engineering difficulties which can be got over, and we shall see in the course of these lectures that they can be.

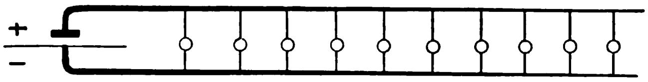
DIFFERENT SYSTEMS OF DISTRIBUTION.

Now we will come to the question of the different systems of distributing our lights. There are several systems which merely depend upon the way of laying the mains; there are other systems which depend upon the introduction of auxiliary appliances. Those which depend upon the way of laying the mains are indicated diagrammatically on the table before you here.



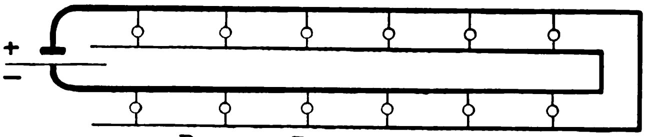
Lamps in Series.

First comes the simplest form, the series, in which all the lamps follow one another in series on a single conductor. Next we have examples of multiple arc systems; in the first one, which I call the parallel line, two conductors diverge from the dynamo, and the lamps are put



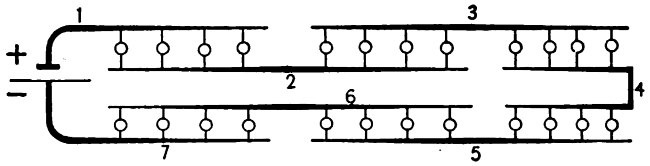
The Parallel Line.

on across the lines. In another kind of multiple arc system, which I call the reversed parallel line, there are two conductors going the whole way round, one end of one of the conductors connected with the positive pole of the



Reversed Parallel Line.

dynamo, and the other end of the other conductor connected with the negative pole of the dynamo, and the lamps are placed across these two conductors. Besides these two systems of multiple arc arrangement there are several others which I shall treat of presently. Passing from these multiple arc arrangements we come to an arrangement which may be called the multiple series, where we have a number of conductors—numbered 1, 2, 3, 4, etc.—the first of which is connected with the positive



Multiple Series.

pole of the dynamo and the last of which is connected with the negative pole of the dynamo, and the lamps are placed, some between 1 and 2, some between 2 and 3, and so on.

The oldest arrangement which was proposed for establishing extensive systems of electric lighting was on the series arrangement; in fact in reading over the evidence given before the House of Commons Committee in 1879 you will find that the series arrangement is the only one spoken of. In using it for incandescent lamps of course the trouble is that there is such a limit to the number of lamps that can be used; that number is limited by the potential, the pressure which we are able to use in our mains. Up to the present time the highest pressure which has been used, that I know of, for any length of time on satisfactory and commercial principles is 5,000 volts. Well, but if we have our lamps of 100 volts each, then 5,000 only gives us 50 lamps; we should only be able to put on 50 lamps to a series. That is a serious drawback. Another drawback is that if one of these lamps goes out the whole will go out, so that it would be necessary in such a system to have an automatic arrangement so that when one lamp goes out it shall shunt that lamp. It is clear, then, that if we want to increase the number of lamps in our series, it will be necessary to use very low potential lamps, while in the multiple arc system it is desirable to have them of as high potential as possible. In series it is best to have a low potential; but this has a serious objection. If we shorten the length of the filament, or if we thicken the filament so as to diminish the resistance we make the cooling effect of the terminals very great indeed. This is very evident in an incandescent lamp that has a very thick filament, such as the Bernstein and the Lodyguine lamps. I think we may safely pass over the question of putting incandescent lamps in series. Arc lamps put in series are eminently successful, and the arrangements adopted in America for keeping the current perfectly constant are such as to shut off any number of lamps, and keep the others working well. I see around me several gentlemen of the British expedition to America last year, and I think every one must have admired the working of the central arc lighting. When we were in Philadelphia—I speak of it because I know it best—whether we were in the dynamo room, where we saw numbers of dynamos at work, or whether we were walking through the streets admiring the graceful festoons of overhead wires and the elegant steel poles on which they were suspended; and feeling the benefit of the graceful wires and powerful dynamos to thousands of our fellow creatures, we could not help feeling admiration for these central stations.

THE MULTIPLE ARC SYSTEM.

I now come to one of the most important systems of distribution, the multiple arc system. It is the most important for this reason, that it has received the greatest amount of attention in the past. I do not say that it gives the greatest prospect of success in the future. When we

1. Cantor lecture delivered by Professor George Forbes at the Society of Arts, London, February 9th, 1885.

Digitized by Google

come to speak about the multiple arc system, first of all I wish to direct your attention to the necessity for having as high potential lamps as we can. I am informed by Mr. Swan that if there were a demand for it, there would be no difficulty in procuring a 20-c. p. lamp, of as long a life as those which are made at present, supplied with a pressure of 400 volts. With this authority, I am simply surprised that the thing has not taken a more practical shape. It is a most important thing, as you will easily see when you think that a 20-candle lamp with 400 volts, of equal economy, equal life, with the present lamps, means that the number of lamps which a good conductor would give would be enormously increased. Let us first take the simplest case there is of distribution by the multiple arc system, that is a street with conductors going along a single street, as shown in the second diagram; and we should also consider the case of this reversed parallel line as I have called it. Now you notice I have made these conductors tapering, because, theoretically they ought to be tapering, and practically they must be as nearly tapering as they can be, the reason being that at every point the section of the conductor must depend on the current it is to carry. Now the first thing that strikes us in this system is the very serious obstacle, the falling off of potential. I have assumed, for the purpose of illustration in these lectures, a certain size of conductor, 1½ square inches to every 1,000 ampères. That is not in the least the size that must necessarily be adopted, that must depend on local circumstances; but we must have a certain size to continue, and we will take that. When a conductor of that size is carrying that current, the fall of potential is constant whatever the thickness of the conductor may be, because the fall of the potential is not only proportional to the resistance of the conductor, but also to the current which it is carrying. Of course when the number of lights is diminished, the current will be less and the fall of potential less.

It has been proposed to supply all parts of a district with lamps of the same pressure, and to make up for the increased pressure of the conductors near the engine-house by inserting resistances into the lamps, a high resistance in the first and less as you go along, until there is no resistance at the most distant lamp. This is quite intolerable; it is a most objectionable thing to have to introduce resistances, which are simply using up energy. It is also proposed to use adjustable resistances, so that when fewer lamps are on there shall be not so much resistance, and that these should adjust themselves automatically; but any introduction of resistances like that is very much to be deprecated.

Now what is the greatest distance on such a multiple arc system which we can work with econcmy? That depends upon the variation of potential which we allow. In the Edison lamps of 100 volts, I find that the fall of c. p. at or near the state of normal incandescence is about one c. p. for every volt. I think it would be admitted that a variation of 4 per cent. is about all that we can allow in the pressure. Remember that in this I am obliged to consider the engine as perfectly governed, that is that the electromotive force in the engine-house is perfectly under control. We will allow 2 per cent. up and down, 4 per cent. altogether. Let me show you how it will be necessary to arrange the lamps. Here is a length of conductor separating two lamps; the pressure required for the lamps is 100 volts. I raise one to 102, or a pressure two above its normal, and lower the other to 98, two below. We are able, by giving one station a lower potential lamp, and the other a higher potential lamp to make a greater variation without allowing either of them to go more than two per cent. above or below its normal character. Let the near lamps be of 102 volts and the distant ones 98 volts. When all the lights are on, let one be raised to 104 and the other lowered to 96; when they are all off, let the one be lowered to 100 and the other brought to 100 too. There is never more than 2 per cent. above or below, yet we have a range of 8 volts allowed for the drop in the conductor when all the lamps are on, This is simply to show you that we can by stretching a point work at 8 volts instead of 4. I am, however, against supplying a district by lamps of a different character; therefore I prefer to speak of 4 volts as the permissible fall in potential between the nearest and farthest lamp. Assuming that there is in 100 yards a fall of potential of 3·22 volts, which is the case with the size of conductor I have chosen, there is a fall of potential of 4 volts in 124 yards; therefore, on this assumption, if we supply a district with lamps of uniform pressure, the greatest distance which a lamp can be from a central station on economical conditions is 124 yards. This is a very serious thing, and shows how very limited is this parallel line system.

It has been proposed to get over the difficulty of the fall of potential by using the reversed parallel line. In this case, since one end of one conductor is connected with the positive terminal, and the other end of the other conductor connected with the negative terminal, it looks as if the potential would be constant at every point, and so it would be if the wires were properly drawn. You see I have made them tapering, and so they should be; but on the assumption that they are perfectly uniform it has been shown, first I believe by Prof. Ayrton, that the potential is not constant at different parts if there is a greater consumption of light at one part than at another. Mr. Kapp has also shown that even in the case of a uniform distribution of lamps along the whole circuit, if the conductors are of uniform thickness, the potential is not equal at every part of the line, but is greatest at the two ends; but you will easily see that if the resistance of the conductor at every point is inversely proportional to the current which is passing through it, then the potential at every part would be the same if we had the size of conductor at every point proportional to the current it is carrying. The size of copper which is to be used is exactly the same as if we had a single wire for every lamp, an independent wire going for every lamp in the whole circuit; there is exactly an equivalent mass of copper in every part. The tapering arrangement is also analogous; it is equivalent to forming a circuit for every lamp. And you will find in every system of distribution by multiple arc a mass of copper equal to a separate wire for every lamp, this being the law of the amount of copper required in this system of conductors. What does it mean, this equalization of potentials in this way? It simply means instead of leading the wires up and back again, we interpose an additional amount of copper for the sole reason of putting in resistance, and carry that copper the whole of the way round our circuit. That is worse than in parallel line introducing resistance to equalize potential, because it is introducing resistance equivalent to the length of copper wire, and copper is a very expensive material. Why not make it of some much cheaper material, and have simply an ordinary parallel line with resistance interposed? I think you will agree with me that this short statement is absolutely condemnatory of the reversed parallel line. However, that system bears an analogy to the multiple series system, and for that reason the time spent in considering its conditions has not been wasted, because when we come to the multiple series system we shall understand better how the sizes of conductors should be proportioned.

ARRANGEMENT FOR A LARGE DISTRICT.

I now come to the most important part of the arrangement of multiple arc systems, that is, the arrangement for lighting a large district. In the course of these lectures I have a good many special cases sometimes to take which are not applicable to general cases likely to come before the engineer; for example, the size of conductors, the permissible fall of potential, and so forth. Well, in taking the question of lighting a district, since it is impossible to deal

Digitized by Google

with every special district, I have taken a single example. This diagram, figure 1, is a plan of the city of Chicago, and, indeed, of several others in America, of which the names are utterly unimportant. The district is simply made up of rectangular blocks of houses, and I have taken this as an illustrative case to show how the mains would have to be laid. I shall show you that the mains would be laid on three separate systems. To the first system I give the name of tree mains, because it consists of a massive trunk starting from a central station, dividing off into branches, and separating again into twigs and leaflets, and the leaves may be supposed to represent incandescent lamps; then I shall have to speak of a modification of the tree system, which I shall call either the compound or the multiple tree system, in which case a number of different trunks or feeders go out from the central station to different parts, where they branch off; and, finally, I shall have a few words to say on what is called the network system.

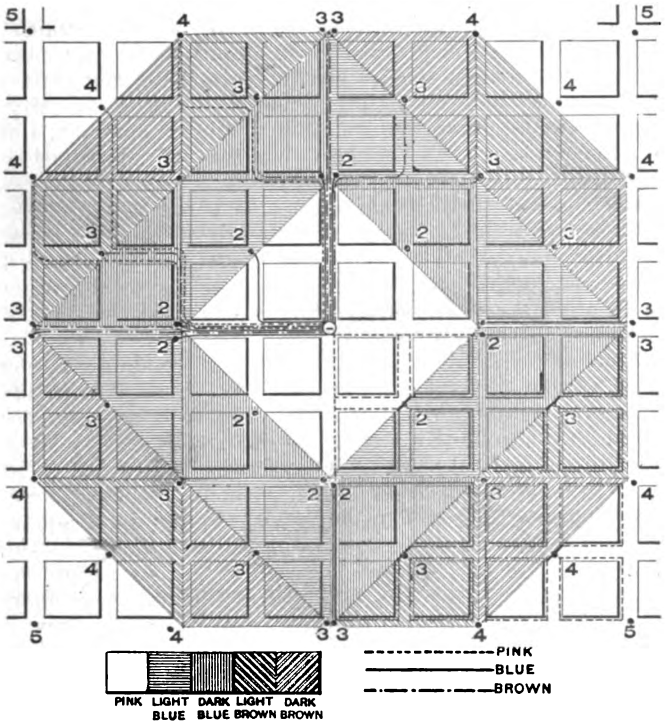


FIGURE 1.

The first thing which has to be done when a district has to be lighted, even before selecting the system of laying mains to be adopted, is to determine the probable consumption of electricity in different parts of the district. This is a very difficult thing to do, of course, and the engineer must bear in mind the fact that the best estimate he can make is probably at fault, and so give a certain latitude in his proportions to allow for probable errors. Another point which it is desirable to get is the probable consumption at different hours of the day and different seasons of the year. These are figures which would probably be fairly uniform in similar districts in different parts of the country, but I have not been able to obtain information on the point. At the same time, I have no doubt that (and especially at gas works) it must be perfectly well known what the average relative consumption is at each of the 24 hours, at the time of the longest day, the shortest day, and at the equinoxes. I should be very glad, indeed, if any gentleman here can furnish me with even approximate data on these points; the information would be very useful. In all the attempts which I know of which have been made to lay down a system of mains, whether it was done on the tree system or the network, there seems to have been a sort of haphazard in the preliminary choice of size of mains and the manner of laying, and then these have been worked up gradually and altered in one way or another. My object is to try to show you that the laws by which these things are to be decided are perfectly definite and clear. The history of research into the matter of distribution is chiefly to be found in the records of the Patent-office. There is nothing more interesting than to read through the various patents which have been taken out, especially by Mr. Edison, in the matter of distribution, and I am glad to take this opportunity of stating how strongly I feel the great forethought which was evinced by Mr. Edison in investigating the matter, so far as he did, at such a very early date in the history of electric lighting. Some of his most valuable and suggestive patents date from the year 1880, when the multiple arc system was in embryo. At the same time I must say that whilst his qualitative suggestions have been so admirable, when he has come to the quantitative determinations and to the actual laying down of the mains, there have been some inexplicable fallings off; so much so, that really in his central station in New York a very haphazard way of laying down the mains has been chosen; and it would have been very well worth while to have calculated the results of the distribution on such a system on paper before laying them down, and I think then most of the difficulties they have now met with would have been foreseen and probably prevented.

That leads me to say another thing about the calculation of mains. When an expensive bridge, like the Forth bridge or the Brooklyn bridge, is to be built, people are not entirely regardless of the amount of metal they are going to put into it. They calculate the weights and strains of different parts with the utmost care, and not simply spend a few hours, but months, and even years, in calculating out these different points. And it is much more important, I think, in laying electric lighting mains, where with 100,000 Edison lamps you have over a ton of copper for every yard run on the multiple arc system, and if you consider the amount of money expended, no amount of care and forethought spent in this direction is wasted time.

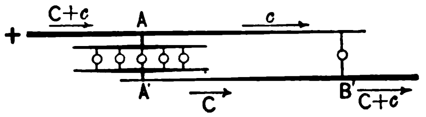
First, take the question of tree mains, or a system of mains which covers the whole district, and the trunks of which are all connected together and to the dynamos. This system was treated very well by Mr. Kapp two years ago, but his views were founded, not upon the economical size of mains, but upon the size of mains which would not vary the amount of potential more than the amount permitted by the board of trade. If he had viewed it simply on the economical size of mains he would not have got further than 124 yards, whereas he was able to deal with a much greater amount. Now, let us see what is the size we may have with the money at our disposal. First, we have n, equal to the number of lamps; then r, equal to the greatest distance of any station; then we have e, equal to the electromotive force of the lamp; p, equal to the percentage variation allowed in the pressure supplied to the lamps. The quantity of copper in the mains in any district of a fixed size is evidently proportional to the number of lamps; it also varies with the most distant lamp in two ways—in the first case, the further you go the greater is the length of mains; but as soon as the length of mains is fixed you must increase the mains so as not to let this fall of potential be greater than in a smaller district. For that reason it is necessary, when we increase the distance of the most distant lamp, we must increase the cost of our mains in proportion to r^2. Then the higher the electromotive force of the lamps the smaller the current, and it is inversely proportional to the E. M. F. of the lamps squared. Mr. Kapp found the cost equal to $k \cdot \frac{n r^2}{p e^2}$ where k is a constant quantity r is given in yards and e in volts, and p is the percentage variation of pressure allowed. He found that when the lamps were evenly distributed over the district k was equal to 1·2; therefore, the total cost was equal to

Digitized by Google

this quantity. Thus, if we were to take 60,000 lamps, n equal to 60,000, r the greatest distance equal to 700 yards, e the E. M. F. of an ordinary Edison lamp of 100 volts, p the variation of pressure taken at 2 per cent. up and down, then the cost of that installation would come out at £882,-000. Now, I would show you how important in this case is the higher E. M. F. of our lamps. If we had 400 volt lamps the cost would be reduced to £55,125. As I have already said, such a system of continuous mains in this way is not consistent with economical principles beyond a distance of 124 yards.

THE MULTIPLE TREE MAIN.

I will now speak to you of a system which I have called the multiple tree main. This system was patented by Edison in 1880, and was adopted by him and others at different times. Mr. Crompton proposed its introduction at Victoria station in 1883, and actually adopted it to some extent in the Law courts. The fall of potential of 4 volts in 124 yards is not necessarily between the station and the lamps, but between the nearest lamp and the furthest lamp which is supplied by that system of mains from the station,



MULTIPLE TREE MAIN.

so that I might have in this way the central station here (indicating), I might have a very long feeding main, and then it might branch off, and I might have one lamp here and other lamps over there (indicating), the distance being 124 yards, and the variation not more than 4 per cent. along the whole length of conductor, provided I keep that point properly adjusted. This was one of the systems provided by Mr. Edison in his patent. Now, the way in which that ought to be carried out is shown in this diagram, figure 1, which gives different colored lines for the different feeder mains which will be required, and I have colored the map in a special way. The pink centre is fed direct from the central station; the blue spaces are fed by distributing boxes marked 2, which are all 124 yards distant from the central station. I have assumed that the distance of two sides of one of these blocks of houses is 124 yards, only to make the thing simpler to describe. The brown district and distributing boxes indicated by the figures 3 are distant along the streets by twice 124 yards, equal to 248 yards, so the pink outside the district marked 4 is three times 124 yards. Then the number of distributing boxes which is necessary is shown here by the number of these marks, 2, 3 or 4, as the case may be. The number is fixed by this consideration, that the distance of the distributing boxes from the most distant lamp it feeds cannot be greater than 124 yards. And here I may draw your attention to an important point which has been almost always neglected in such a system of distribution—that in order to economize copper the distributing box must be nearer the central station than any of the lamps which it feeds. It is almost invariable in schemes for this purpose to place the distributing box in the centre of the district which it feeds. As to the relative size of conductors in different parts of the district, you will see in this arrangement. as in the ordinary tree main system, exactly the same rule holds, that if you will take all the lamps in different parts of your district and lead wires by the shortest route that you can to the central station, then measure the proportional thickness of this bundle of wires in different parts of the route, then you have the most economical proportions of the conductors in different parts which can be given to it, and from the consideration of Thomson's law, you know not only the proportional size of the conductors, but the actual size in every part of the district. Here we have added a most important condition to our actual knowledge: in order to have economical mains we cannot have a lamp further distant from its distributing box than 124 yards, and that distributing box must be nearer to the central station than any of the lamps which it feeds. Thus, if the multiple arc system is to be adopted, this arrangement must be used if we are to comply with the conditions of economy, whatever the difficulties may be of arranging the potentials of the different parts. And here I may point out that it may be necessary to get the potentials of those distributing boxes at fixed amounts. This may be done either by inserting resistances into the trunks and into the feeders which go out from the central station (this is the plan which Edison adopts), or it may be done by using a separate dynamo for every distributing box, or by diminishing the E. M. F. by diminishing the resistance, by varying magnetism of the field magnets; or, as Messrs. Willans & Crompton have been doing, you may govern your engine by an electric governor, which is regulated by the potential of these distributing boxes, so as to keep that potential constant; or you may proceed in other ways: you may have large dynamos to give you 100 volts in all your mains; then you may put in smaller dynamos in large quantity, capable of increasing the E. M. F. by a similar amount, and thus may supply the different centres of distribution. These are points to which I should like to devote a very long time, for a great deal can be said about them; but it will be impossible for me to get through the simple matter of laying mains if I go into the question. Therefore, I must omit further reference to it, as well as to the other important matters connected with the general scheme of distribution.

Now, as to the cost of this system of conductors: you will find that the cost is not nearly so great as with the tree main system. I will give you the data required for calculating out the cost. What is the cost of the feeder to the first nearest distributing box, that is, 124 yards? That is the same as the most distant lamps in any square. Therefore, that portion of a feeder which lights up a square requires twice as much copper as the copper that is in the square. Some of the supply wires of the square go the whole length of 124 yards, but some of them are very short indeed, and the average length of wire in that square is half the length of the feeder main, so that up to the first distributing box the feeder main has twice as much copper as the district which it feeds; therefore, the whole length of the feeder to No. 3 feeding box has four times as much copper as the spaces which it feeds. These are the principles on which you must calculate the expense. You will then find that in the inner district, the cost being L, equals the cost of conductors for one square; then next the central square consists of eight squares, and the cost is eight L, and that gives us L pounds per square of houses. In the second district you will find on calculating it out that it is 2·5 L per square; in the third district it is 3·8 L; in the fourth, 5·2 L. Now compare this with the single system of tree mains, taking Mr. Kapp's data. The first district comes out on an assumption of 200 lamps to the square at £8,000. But look at the second, third and fourth districts. In this table you see the comparative cost with and without feeders:—

	No. of Squares.	Cost.	Cost without feeders.	No. of Lamps.
		£	£	
1 district	8	8,000	8,000	1,600
2 districts	32	90.000	128,000	6,400
3 "	72	280,000	648,000	14,400
4 "	128	672,000	2,048,000	25,600

THE NETWORK SYSTEM.

I will conclude with a very short reference to the network system; only a few remarks are required, because

Digitized by Google

the network system is nothing more nor less than that which we have just investigated. There is simply this difference in it, that all the different squares may be connected together, the positive to the positive, and the negative to the negative mains. If all these squares were connected together, the positive mains and the negative mains of the different squares, we should have to choose our conductors exactly of the same size as we have chosen them here, and should have exactly the same conditions. If our conductors were chosen of the proper size for the current flowing, then the current in that case would flow along exactly the same channels as under the system I have been describing; the connections between the squares would have absolutely no effect. That would be the case when we had the maximum number of lamps on. It may be, however, that when the distribution is varying in different parts of the district it may be an advantage to have these different squares connected; and it may also have this effect, that when anything went wrong with a feeder it then would not put a district into total darkness, because that district would be partially lighted with the other feeders. That could be avoided by making each feeder double, because it is very unlikely that two feeders would be injured at the same time. The difficulty in designing the network system up to the present time has been where to put the distributing boxes. Mr. Edison—and possibly others have followed in his lines—has drawn out plans for central stations without considering where to put the distributing boxes at all. This is putting the question in the wrong order; it should be first where to put the distributing stations, and what the size of the conductor; then our network system builds itself up in proper form and dimensions. I need hardly say, if we are to act upon economical principles, and have a variation of potential of not more than 4 per cent., we must have our distributing boxes exactly the same here as in the independent wire system.

We have then arrived at three very important results: first, we must have a large number of distributing boxes, and these distributing boxes must be nearer to the station than any of the lamps fed by them; the distance of the most distant lamp from a distributing box must not be over 124 yards; and the proportionate section of the conductors in different parts of the district must be the same as if we had independent wires coming from every lamp in the district to the central station. Now, when I have used the expression of 124 yards, you must not for a moment consider that as binding; this, as well as the economical size of conductor and the percentage of variation allowable, is dependent upon local circumstances.

THE DANGERS OF MECHANICAL GENERATORS OF ELECTRICITY.[1]

THE more and more general use of powerful electro-magnetic generators has caused several accidents, some of them involving the loss of human life. It is, therefore, desired at present to regulate the employment of electricity, and to determine experimentally the tension and the current which are dangerous in practice. The problem thus set forth is not well put, and is not susceptible of any solution, as the object of the present communication is to show. In the first place, it is not, generally, when the electric current is permanently established that accidents take place, but at the moment of the establishment or of the rupture of the electric circuit. Under these circumstances, the body of the experimentalist re-establishes for a longer or shorter time the continuity of the broken circuit. It is easy to show that, at this moment, the danger incurred depends by no means on the tension and the intensity of the primitive current, as is generally believed, but depends on quite a different factor, which cannot be calculated from a mere knowledge of the tension and the intensity of this primitive current. All physiologists know that the energy of an electric excitement depends much less on the intensity of the current than on the rapidity of the fall of the potential and on the frequency of the shocks. This being established, the following propositions become, so to speak, self-evident :—Proposition I.—A battery and a machine producing in a rectilineal circuit two currents having the same current and the same tension do not present the same dangers. In fact, if we break the circuit in any point whatever, holding in each hand an end of the uninsulated wire, we find that the battery gives scarcely a shock, whilst the machine produces a much more considerable excitement of the nervous and muscular systems—an excitement which, in certain cases, may become instantaneously fatal. The reason of this difference is that the battery in a rectilineal circuit does not give an extra current, whilst the machine, by the mere fact of its construction, gives one, the power of which varies with the length and the manner of coiling of its circuit, as well as with the quantity of iron which forms its framework. The danger, therefore, resides simply in the power of the extra current resulting from the self-induction of the generator. From these very simple considerations, the results of experience, we deduce the following propositions. Proposition II.—Two machines yielding currents of the same intensity and the same tension in a similar circuit may be unequally dangerous, since their coefficients of self-induction, and consequently their extra currents, may be very different. Proposition III.—A current not dangerous in one circuit may be dangerous in another. It is merely necessary to give the circuit a self-induction by any means whatever—*e. g.*, by the interposition of an electro-magnet. I have verified experimentally these theoretical deductions by operating upon Guinea pigs with a Gramme machine (laboratory model) and with accumulators. The tension of the currents employed varied only from 2 to 20 volts, and the current from 1 to 30 ampères. Notwithstanding the feebleness of the currents employed, the Guinea pigs were nevertheless killed. We see, therefore, that, if we wish to suppress all danger in the use of electricity, we arrive at the absurd conclusion that electricity itself must be suppressed. I have sought for a remedy for this state of things. This is the method which has proved efficacious in all cases, and which constitutes a general procedure for the suppression of extra currents. To avoid all danger, what, in short, must be done? Simply prevent the extra current from traversing the body of the experimentalist. We know that the tension of the extra current is infinitely greater than that of the primitive current from which it takes its rise. This being admitted, I place in derivation at the extremities of the electric generator a series of voltameters, with lead plates and acidulated water, in such a number that their electromotive force of polarization may be superior to the maximum electromotive force of the machine. This derivation is absolutely impassable by the direct current, while the extra current traverses it readily. At the moment when the circuit is broken the extra current passes through the voltameters, and the human body is absolutely secure. This is a general and very simple method for the suppression of extra currents. It admits of numerous applications, some of which I have already carried out, but their explanation cannot be given in this brief notice. I take voltameters with leaden plates because they develop practically the greatest electromotive force, and I vary the arrangement according to circumstances. We see that the process which I propose consists in the establishment of a derivation, insurmountable for a direct current, and consequently occasioning no waste of current. This derivation exists only for the extra current. It is analogous to a safety valve, which opens automatically at a given pressure.

SOLID v. LAMINATED ARMATURES.[1]

BY SELIMO R. BOTTONE.

CONTRADICTORY statements have appeared in several publications devoted to electrical matters as to the relative efficiency of solid and laminated armatures. In manufacture, a laminated armature is certainly more expensive; hence it must present some decided advantage over the solid form to insure its adoption.

In order to decide the point by actual experiment, the writer fitted up a small dynamo (one of those described in his book) with 7 lbs. of No. 16 c.c. copper wire on the fields. Two armatures, each 1½ in. in diameter, 3¾ in. in length, with a channel ⅛ in. wide, and a web ¼ in. in thickness—one, *a*, solid, weighing 13 oz.; the other, *b*, laminated, weighing 11 oz.—were each wound with 16 oz. of No. 20 silk-covered wire, and then soaked in melted paraffine to insure good insulation. These were both mounted on spindles of the same size, fitted with similar commutators, and, in point of fact, rendered as identical as it was possible for them to be, except in the point of lamination.

When the solid armature, *a*, was fitted to the dynamo, worked as a series machine, it was possible, by driving at a speed of about 3,000 revolutions per minute, to light fairly well four five-candle Swan lamps, arranged in parallel arc, having each a resistance of eight ohms. At this speed the electromotive force was about 10 volts at the terminals.

The laminated armature, *b*, was now substituted, and on trial it was found that the five-candle Swan lamps could be kept brilliantly lighted by a speed of 2,000 revolutions per minute. On adding lamps, and increasing the speed, it was found that six, and even seven, fives could be lighted up, and at 3,000 revolutions the effect with six was as good as the solid armature gave with four. The electromotive force of this machine at this speed was found, on careful measurement, to be about 20 volts; and, in point of fact, it was possible to light well three 10-candle Swans in parallel arc each of 20 ohms resistance. With regard to heating, *a* rose from a temperature of 45° F. to 120° after a 20-minutes run; *b*, after running 20 minutes, had only increased 5°.

In order to render the experiments more conclusive, two exactly similar motors were fitted up, alike at all points except in the armatures. The armatures, *a* and *b*, were fitted to these motors, but so as to be interchangeable at will. No material difference was, however, detected in the field-magnets. These two motors were connected up in series, but back to front, so as to get the driving-wheels to run in opposite directions. The two driving-wheels were then joined together by an endless band, and the motors joined to one and the same battery (so that the same current circulated round both at the same time).

The result was that the motor fitted with the laminated, *b*, armature began to revolve, dragging with it armature, *a*, which was thus obliged to rotate in a direction opposite to that in which it was impelled by its own field-magnets.

To what may this superiority be attributed? Probably three causes are at work simultaneously.

1. The sheet-iron from which the laminated armature was made is softer, more free from carbon, and purer than it is possible for cast iron to be; hence more rapid and more perfect magnetization and demagnetization.

2. The lamination, and consequent separation of the portions of the armature, prevents the formation of the Foucault currents; therefore, the iron core does not get heated.

3. The interstices between the laminations, by allowing the passage of air, help to keep the armature cool; and the coolness of the armature favors the conductivity of the wire, and consequently the efficiency of the machine.

ABSTRACTS AND EXTRACTS.

LIGHTHOUSE EXPERIMENTS.

THE long series of experiments made during last summer and autumn at the South Foreland to test the respective merits of oil, gas and electricity for lighthouse illumination, have been brought to a close, and the reports will now be drafted and published. Pending their appearance—which will necessitate some delay, owing to the voluminous character of the observations—we may mention that the evidence is in favor of the electric light on the whole, because of its far-penetrative power. While the rays of oil and gas-lights were lost sight of at a distance of eight miles, the electric light could be seen for 14 miles; and with gas or oil at its maximum power, and visible for 10 miles, the electric light could be seen for 14½ miles. Although the arc is very much reduced in fogs, it still appears to be visible further than gas or oil. By direct testimony of observers, the electric light became visible in dense fogs at a distance of 1,900 to 1,500 feet, whereas gas and oil were only discerned at distances of from 1,500 to 1,250 feet. This is an important point, because it was thought that gas and oil might have the advantage over electricity in dense fogs. There is no doubt that fog does quench the direct rays of the arc light in a remarkable manner; but how much this would diminish its efficacy in a practical sense was not well known hitherto. Probably the white haze surrounding the lamp is detected for a considerable distance, although the arc itself in a fog has lost its brilliance. So long as this haze is seen, mariners will learn to distinguish it as the lighthouse. The heating due to the use of gas was found to be very considerable. With the original 88-jet burners, the temperature rose to 200° F.; but the subsequent use of 108-jet burners brought it to 300° and 350° F These burners gave an illuminating power of 2,400 candles. The electric arc lamps used gave a light of 12,000 candles each. Four of the gas-burners were superposed in a quadriform arrangement, and three arc lights were sometimes used. For the oil lights, the Trinity House six-wick burners were employed, each giving a light of 800 candles. We may add that, although the experimental trials are for the present over, the photometric observatory and testing towers will be allowed to remain for further use and testing purposes. This is a sensible decision, since, whatever the result of the trials at present, they cannot be regarded as conclusive while the subject of illumination is engaging so much attention.—*Engineering* (London).

ELECTRIC LIGHT ENGINES ON SHIPBOARD.

COMPLAINT is made by some that electric light engines on shipboard do not run regularly, and cause a great deal of trouble by this defect. On some lines, or some vessels, the electric light has been abandoned for this cause. On shipboard electric light engines are connected with and exhaust into the condenser, and this has been a source of trouble also from choking the same. To speak more correctly, the condensers would not do the work, for they were only large enough—and none too large—for the main engines. An electric light engine at work, small though it be, consumes in cubic feet a great deal of steam, and throwing this into the condenser of course creates just so much additional work. Moreover, the exhaust is so rapid that it may almost be termed continuous. It is different in its action on the condenser where the surface is already needed for the main engines from the intermittent action of their exhaust. The cause of irregularity is to be found, we think, in exhausting into the condenser. This takes away the compression, upon which electric light engines depend, to a great extent, for their regulation; there is no other reason why engines of this class should not run as well on shipboard as elsewhere.—*Mechanical Engineer.*

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

A SUCCESSFUL MOTOR.

[33.]—Under the head of "Questions and Answers," page 147, Vol IV of the ELECTRICIAN AND ELECTRICAL ENGINEER, I saw a communication from L. T. W., stating he had made a motor in accordance with the directions given in the ELECTRICIAN AND ELECTRICAL ENGINEER, and can get no result with four cells of the Eagles battery. By "getting no result" I am led to suppose that the machine will not run with the battery power above mentioned; whereas, if properly constructed, it should certainly do so with even less.

Nearly a year ago I made a motor about the size of that now being described in your columns, from which I think I get excellent results. For example, it will run at the rate of about 500 revolutions per minute with one small cell of Smee's battery, of the size used in medical apparatus (plates 2x3 in.). With one small bichromate cell (zinc plate 1½x3 in.) the armature attains an extremely high speed, and with four such cells it will run an ordinary shuttle sewing machine at the rate of about 400 stitches per minute while sewing three thicknesses of heavy sheeting. With a battery of six larger cells (plates 3x6 in.) I run my lathe for turning metal, and can do work as rapidly as when running by foot power.

There are several points not to be overlooked in constructing an efficient electric motor, of which there is no mention made in any work I have seen on the subject. E. F. COLE.

ARKWRIGHT, N. Y., April 22d, 1885.

MERCURIAL PENDULUM CONTACT.

[34]—A correspondent writes as follows: "I purchased last winter a good clock which has a seconds pendulum, with the intention of using this pendulum with a circuit and sounder to beat seconds in my observatory. I placed in the lower part of the case a piece of vulcanite with two depressions, in which rest two globules of mercury. Wires leading from the globules make the circuit when a light iron fork attached to the pendulum passes through the mercury as the pendulum vibrates back and forth. Now this fork passes through the mercury freely, and does not interfere with the running of the clock; but when the circuit is made it invariably stops the clock within an hour. I have repeatedly tried it, and always with the same result. The clock will run for days or weeks, and will stop every time the current is made to pass through the fork from globule to globule of mercury. The question is, why is there any more resistance to be overcome when the current is flowing than when not?"

[We cannot give a reason for the stoppage of the clock arising from the action of the current as stated. If any of our readers have met with similar experience, and can explain the cause, we shall be pleased to learn the result of their investigations.—EDITOR.]

QUESTIONS AND ANSWERS.

[66.]—**Course of Electrical Engineering.**—F. F., of Hartford, inquires for information as to what college gives instruction in electrical engineering. Ans.—There are now several colleges and technical institutes of good reputation which give such a course of training. Consult our advertising columns.

[67.]—**Castings for a Motor.**—J. S. L. wishes to know where he can get the castings made for the motor described in these columns. Ans.—It will first be necessary to make or obtain the patterns, after which we presume any foundry devoted to small work will make the castings from them. Some of our readers who have made such motors will possibly give the result of their experience.

[68.]—**Small Incandescent Lamps.**—J. H. F. inquires whether an electric lamp can be constructed and run with a battery whose power will be equal to an oil lamp. How many cells would be required; how long would they last, and what would be the cost per light? Ans.—The manufacture of such lamps and batteries to supply them is now a regular line of electrical business. They are made of various sizes. See our advertising columns.

CORRESPONDENCE.

NEW YORK AND VICINITY.

More Overhead Electric Light Wires.—The Ticker Business Unchanged.—Senator Kiernan Proposed for Assistant Treasurer.—Electric Lighting in Brooklyn.—Impecunious Telegraph Companies.—Long Distance Telephony.—A Whirling Cat in Brooklyn.—Stored Electricity for Sale.—The State Press Looking for a Telegraph Line.—Electric Railway Progress.

THE United States Illuminating Co. is quietly erecting its lampposts through Fulton street in order to carry out its contract with the city. There are at present no indications of the conductors being placed underground to supply the current to this extension of the system. With the exception of the Metropolitan Telephone Co., there appears to be little activity displayed in preparing to comply with the requirements of the underground law, possibly owing to the reason that its provisions cannot be understood. At this date, the bill for the appointment of commissioners to enforce the law has not been signed by the Governor. The Arcade Railway bill is in a similar condition.

Since the expiration of the Calahan patent last month, the Commercial Telegram Co. has continued the use of its tickers, with both type-wheels; and although some subscribers have relinquished the service through fear of legal complications, there are no surface indications of the suppression of the business,

Since the announcement that the Hon. John J. Kiernan, of the Second Senatorial district, would not be a candidate for reelection, he has been mentioned as a possible successor to Thomas C. Acton, assistant treasurer in this city, whose term expires December 31st. Mr. Kiernan has long been identified with the interests of Wall street, and has built up a lucrative business in the dissemination of financial news through his ticker system and manifold slips. His office is still located in the old building, 21 Wall street, where he entered business life as a messenger boy some 30 years ago. Having served two terms as state senator, he is in every sense of the word a well-known man, and his appointment to any public trust would be heartily endorsed by the community.

The Brooklyn aldermen have granted the Citizens' Electric Illuminating Co. the right to light certain thoroughfares of the Western district, the lamps to be each of 1,200 candle-power. If the aldermanic resolutions become operative, 152 electric lights, of 1,200 candle-power, 200 feet apart, would be required on Fulton street, from the ferry to Bedford avenue; Myrtle avenue, from Fulton to Bedford avenue; Atlantic avenue, from the ferry to Fifth avenue, and Court street, from Joralemon to Atlantic avenue. The cost of the lights would be $27,740, or $182.50 each per annum. Should the lights be of 2,000 candle-power, 270 feet apart, 108 lamps would be required, costing $27,594, or $255.50 each. The number of gas lamps displaced would be 852, which cost yearly for lighting $17,483.40.

General J. G. Farnsworth has been appointed receiver of the Bankers and Merchants' Telegraph Co., which is still struggling along. A report has been current that it would be brought into the fold with the Postal Telegraph and Cable Co., which is again to be reorganized. It appears to be a serious undertaking to maintain a competing system under the rates which now prevail.

At a meeting of the Polytechnic Association at Cooper Union, May 21, Mr. A. M. A. Beale delivered a lecture on long-distance telephony, giving a description of the experiments in that direction made between New York and Chicago last winter. He stated that Mr. Gillett, the inventor of the instrument in question, was now in England, and that he proposed to undertake a series of experiments over the cables of the Commercial company during the coming summer. Mr. Beale is now engaged in preparing the instruments for this trial. It will be of interest to those who are anxious to invest in a project of this kind to know that one of the oldest, and perhaps the most thoroughly scientific American electrician, has made a calculation as to the capacity of a conductor required for successful telephoning across the Atlantic. He states that it would be necessary that the copper core of the cable should be 17 feet in diameter, with an outside gutta-percha insulation 5½ feet in thickness, making a total diameter of say *twenty-eight* feet.

A remarkable cat story comes from an electric lighting station in Brooklyn. The engine furnishing the power has a large fly-wheel running in a pit. Recently the cat of the establishment was calmly reposing on the inside rim of the wheel in the pit, when the engine was started up for the night run, and was soon making 20 revolutions per minute. As the cat could not be rescued without stopping the engine, and consequently throwing the district into darkness, the bewildered animal was compelled to continue in its orbit for seven weary hours, when steam was shut off at the usual time for extinguishing the lights. The cat dropped from the wheel in an exhausted condition as the speed slackened, but soon revived, with no indications of injury from its curious experience, after its excursion of about 300 miles.

The time has apparently arrived when stored electricity may be purchased as required; but intending consumers should state for what purpose the current is to be used, and in what quantities,

Digitized by Google

when, as the advertisement in the daily press announces, "estimates will be sent." The public has, however, been educated up to a point where they will doubtless hesitate before ordering a very large supply of "bottled electricity."

A very important meeting of the State Associated Press was held in this city on the 20th. Resolutions were adopted directing the executive committee to lease a wire from the Baltimore and Ohio Telegraph Co. if the Western Union insisted on charging an exorbitant price for the same; and the committee was also instructed to report details of a proposition to build a telegraph line through the state for the association and for commercial business.

Electric railway matters are quiet, as it is now generally known that the work of preparation is actually going on. In the course of another month it is probable that an actual trial will be made. The generating station for the Second avenue line will be in Twenty-fifth street, where a suspended sugar refinery has been rented, having a 2,000 h. p. Corliss engine.

NEW YORK, May 22, 1885.

CHICAGO.

Legal Complications Arising from Underground Privileges.—The Tribulations of the Bucket-Shops.—Opening of the New Board of Trade Building.—Burning of a Cable House.—A Coroner's Jury Enlightened by an Electrical Expert.—The Western Union Company Decides to Pay for Overtime.—Indiana Telephone Construction Suspended.—A Monster Underground Cable.—New Incandescent Systems.

UNDERGROUND matters are progressing in Chicago in more ways than one. While the Baltimore and Ohio, the Western Union and the Chicago Telephone companies were busy drawing their wires under the surface, the Chicago Sectional Electric Underground Co. drew the Postal Telegraph and Cable Co., the Bankers and Merchants', Richard S. Newcombe and James G. Smith, into the U. S. Circuit Court, to compel the defendants to fulfil their agreement. The complainants, organized in 1882, were authorized by an ordinance of the City Council, to lay pipes and subterranean wires throughout the city. A lease was made to Elisha Gray to use the lower portion of a conduit from 39th street to the office of the Postal company corner of Lasalle and Washington. This lease was subsequently assigned to the Postal Telegraph and Cable Co. An agreement was made by the complainant with the Bankers and Merchants' company, granting an exclusive privilege for nearly a quarter of a century, to construct maintain, repair and operate in the south division of the city, such lines as they might elect, in the underground company's conduits, but these privileges were not to be transferred to other parties, a forfeiture of rights to inure from violation of the provisions of the contract. The Postal company for its right to use one-half the conduit already laid paid $35,000 in its bonds at 60% of their par value; $21,000 in additional was paid for the balance of the same conduit, and $14,000 was to be paid for additional rights.

Last year the Bankers and Merchants' laid a large amount of pipe, and the Postal company claim to own rights in this also, having purchased privileges of the Bankers and Merchants'. The complainant claims that this was contrary to the Bankers and Merchants' agreement, and prevailed upon the receivers of that company to cut the Postal's wires. Then the latter company petitioned for an injunction, and the Bankers and Merchants' company notified the Underground company with the attenuated cognomen to protect them. It was much like the cry of "save me from my friends," for the complainants were already claiming breach of contract against the Bankers and Merchants', and also that there was conspiracy on the part of the two defendants. A temporary injunction was granted, restraining the Bankers and Merchants' from interfering with the Postal. Finally, and to conclude, Parker of the Postal company has been made receiver of the Bankers and Merchants', the Underground people have quieted down, and the suit has been dismissed by mutual consent. Peace reigns in Warsaw.

There is rebellion in the open board of trade, and the bucket-shops are stricken with trade paralysis. In the new board of trade just opened the sound of the telegraph instrument is heard no more. Anything for the outer world is sent by tube, to the operating room, and the bulls, bears, and other wild animals outside the precincts of the royal circus arena, are without quotations. The occupation of the curb-stone and C. N. D. brokers is no longer a thing of racket and a row forever.

The claim of the board for some time has been that it should be permitted to dictate to whom the news it furnished should be given by the Western Union, as a means of protecting its legitimate business, and claims that the telegraph company has been furnishing the markets to bucket-shops and other traders of low degree, who are thus enabled to speculate as well as their betters. On the other hand the bucket-shops claimed the right to receive the markets as provided in contracts with the Western Union company, and loaded the latter down with injunctions to compel the service they claimed. The attorney of the board saw an escape from the dilemma in the moving of the board, and claims that the injunctions could only hold as to the wires from the old board rooms. New wires could not be used for the carrying out of the old contracts, and so, as soon as the new building was moved into, the bucket-shops had no rights to enforce. Meantime the irate open board and the bucket-shops are in a quandary, whether to trade on New York or St. Louis quotations, and in doubt whether, if they do this, they may not get brought up with some other round-turn invention of their common enemy.

The opening of the new board of trade building was a grand affair. Twenty Sperry arc, and nearly a thousand Edison incandescent lamps lit up the gay and festive scene. The floor of the new building is capable of holding comfortably a number of talking gentlemen far in excess of the former one, and of course the increased noise and confusion is in proportion. Any ordinary signal bell is readily drowned in the racket, and as for the secretary's mallet being heard, it is utterly impossible. It might just as well be made of cotton batting and struck on a sofa cushion. To remedy the difficulty, application was made to E. B. Chandler, general western agent of the Gamewell Fire Alarm Telegraph Co., who arranged one of the largest electrical gongs used by fire departments, so that if one is really listening for it when it is time to strike it—which is done by Ed. Whitford, by a key—one *can* hear it. The trading room of the new building has been christened "Amusement Hall."

On Friday, the 9th inst. the cable house at the north end of the Lasalle street tunnel took fire and was fairly gutted, cutting off all the telegraph wires running north from Chicago, all the District wires, and all the Chicago Telephone Co's. wires which crossed the river at that point. But the city, whose wires were placed underground last season, had not a wire injured, as these were well out of the way. Prof. Barrett is in high glee at this new practical proof of the beauty of the "ground hog" system. Had the fire-alarm and police-wires been in the same position as formerly, these too would have been sacrificed, and an accident of that nature with such a gale as was blowing that day might have cost the city millions of dollars. As it was, over half a million was lost in the south division during the afternoon, by a lumber fire, which, if the signal had not reached the central station, would not unlikely doubled or probably quadrupled the loss, or enough to bury in good shape, every wire in the corporation limits.

Willoughby, Hill and Co., have lately changed their Brush plant so as to bring all their lights which formerly adorned the two fronts of their building at the several stories, to posts at the curb-stone line, where they are aggregated in groups of three, triangularly arranged. These are covered with red, white and blue globes. The design is unique, and quite attractive. The wires are brought from the basement of the building to the foot of, and carried through the centre of, the posts.

While experimentally running the dynamo on the 22d of April, Mr. Chas. B. Schultz, an employé of the Western Electric Co., who were doing the work, mounted a 12 foot ladder to adjust a lamp which refused to burn. In some way he managed to get a shock which partially paralyzed him, and he grasped the bottom frame of the lamp, which not being rigidly fixed, swayed with him, and he fell. As soon as it was seen that he was in trouble, and in response to a scream, the engineer ran to the dynamo, and opened the circuit. Schultz fell about that time, and his skull was crushed by striking the pavement. This fact, in the absence of other information, gave the public the idea that the extra current, at the time of opening the switch killed him. Then again, to brace himself on the ladder, he had placed his foot on the diagonal brace of the pole—ergo it was a ground connection, and *that* killed him also. The coroner's jury had a fearful struggle, and adjourned for expert testimony. The city inspector was sent for, who showed that the ground theory was impossible, as the insulation resistance was over 1,000,000 ohms. That the extra current could not have killed him, for both hands had hold of the negative side of the lamp, and of course no current could have gone through him. A lecture on currents, direct and derived, and sundry other things, illustrated with diagrams, and the facts in addenda, that his internal organs were uninjured and that his hands were not even scorched, and that the lights were not extinguished, finally convinced the six reasonable jurors and a verdict was rendered in effect: "that he was rendered partially insensible by a shock, and was killed by the fall." Mr. Baron, who was aiding Schultz, holding the foot of the ladder, undertook to break his fall, but, as Schultz weighed something like 220 pounds, his efforts were futile, and both fell, fortunately without injury to Mr. Baron.

Quite a stir lately arose in the operating-room of the Western Union, on account of the decision cutting off pay for overtime made by the employés. A petition was circulated and signed by the majority of them, and formally presented to sup't Tubbs. There were meaningless talks of striking, but the wounds in the war of two years ago were not forgotten by the veterans, and it was only talk. Finally the company compromised the matter, and agreed to payment for overtime based on the hourly compensation for regular work, and the war ended without bloodshed.

The action of the chronic dyspeptics in the Indiana Legislature has induced the Central Union Telephone Co. to shut down on all construction until all the state legislators have gone home to their plowing and pettifogging. In the meantime the unjust law, as the company thinks it, will probably be brought to a test in the Supreme Court of the Hoosier state, and either better or worse times for the company will result from the decision. The horny-handed granger is fast learning the ways of the "stand-and-deliver" gentry, and becomes each year more proficient in the "come-and-see-me" policy.

The Western Union company's cable between the office and the new board of trade, is one of, if not the largest underground cables ever successfully placed. The size and general appearance of the snaky monster reminded one of a garden hose. The entire length from the operating room at the corner of Lasalle and Washington streets to the farther terminal at the new building is half a mile, composed of three sections of 2½ tons each, or a total of 7½ tons. It contains 61 conductors of No. 16 B. W. G., each covered with $\frac{3}{32}$ thickness of kerite insulation; 338 feet of this electrical anaconda are consumed in getting round and through the basement of the new building. Mr. E. B. McClees, of Day's kerite establishment, where the cable was made, superintended the drawing in of the cable, and after joining up the three sections, tested it out, and turned it over to the telegraph company a perfect and complete job of cable laying. No portion was injured in the least, but its immense weight was sufficient to unship the bed of a heavy safe wagon, which carried the mechanical gear used in drawing it into the pipe. The wires are arranged in concentric circles, with one marked wire in each of these aggregations. By this means any wire may be selected at will.

Lasalle street is now about as full of pipes, wires, conduits and things as a grand piano or the harp of a thousand strings is of wires. In future ages when we have all passed over the river, when present systems have become a thing of the past and wires are no longer needed for communication, according to one of our local poets, the crumbling remnants of these, if they do leave any sign, will be a marvel to the antiquary. He says:

"The streets are filling with grave-yard plants—
To earth the wires must go.
The Fire-Alarm and the blue-box lines,
The District and B. & O.,
The B. & M. and the M. U. T.,
And the Western Union too,
The 'lectrical Sectional Underground
And the Telephone—all must go.
And a thousand years from the present date,
When the diggers delve below,
They'll ask "what the dickens are these fool things
I'd really like to know?"

Two new forms of incandescent lamps are about to claim attention here. The Opperman, manufactured in Chicago, and the Stanley, from Pittsburg. The latter is to be run by a three-wire system, in which the central conductor leads to one pole, the two outer ones to the other. The object is to utilize an arc current for both incandescent and arc lamps. As a safeguard against accident each group of lamps is so placed that an equal number is attached on either side the central wire, thus balancing a differential solenoid through which these wires run to the main wires of the arc circuit. Any change in this balance permits a movement of the solenoid core through excess of current in one of the coils, and this results in rupturing the circuit.

The Opperman lamps are made to order, of any resistance, form or capacity required. The firm is driven with orders, and rumor has it that a goodly number of these will make their presence known here in the near future, by their light.

Then there is the Bain company, about which little has been said for some time. Under a new organization the company proposes coming once more into the field, this time with a combination system.

The Mather-Perkins people too are moving. The plant in the Grand Opera House, which has only been in place a few months is already too small and is to be enlarged, while other plants under the same company are expected to take form and blossom before the heated term.

Unless some unforeseen misfortune overtakes the electric light interests, Chicago will soon recover from the black eye the convention gave her, and the next time the association meets here, will be as bright as the best, and the wires will all be underground too.

CHICAGO, May 14, 1885.

WASHINGTON.

The Thomson-Houston System Coming.—A "Pump-log" Subterranean Line.—Wires Ordered off the Government Buildings.—Progress of the Telephone Underground Work.—The Washington Telephone Co.—Proposed Consolidation of the Local United States and Brush-Swan Companies.—Telegraph Messengers on Bicycles.—Legal Proceedings Against the Erection of Western Union Poles.

A NEW electric light company has just been launched upon the Washington public, to use the Thomson-Houston arc light. This was originally intended as a private plant by two of the most prominent business houses on Seventh street, Messrs. Saks & Co. and Lansburgh & Bro., who, at the request of their neighbors, took in so many to share the anticipated benefits, that it became expedient to form an incorporated company. The plant will be located on G street, near Seventh, and the wires run wholly underground down Seventh street, and a short distance westward from Seventh street on Pennsylvania avenue. Although a comparatively small beginning, this enterprise may grow to be one of considerable magnitude, under favorable circumstances. Permission has been obtained from the authorities, and the laying of the wires will shortly be commenced.

Our commissioners have adopted rather a novel plan for the underground cable work. The Western Union Telegraph Co. is to foot all the bills, while the work is done under the direction of the commissioners, the latter thereby assuming all responsibility for damages in laying two 100-wire cables from the company's office, corner Fifteenth and F streets, through F and Fourteenth streets and New York avenue to Seventh street, whence they are permitted to erect a new pole line along Seventh street to the boundary. The cables and air line are each a little less than a mile in length. The conduits for the cables are squared cypress timbers, about eight by eight, with a five-inch hole bored through them, from six to eight feet in length, and joined by dowels. These are laid side by side for the two cables in a trench about two feet deep, and covered up. At intervals of 400 feet openings, about 30 inches, are left between the conduits, and these openings are covered with neat cast-iron boxes. An ordinary No. 9 iron wire is run through each 400 feet from one box to another, and when the work is done the cable is to be drawn from the reel at the main office through these several "man-holes" to the eastern terminus. The cables are without metallic covering, and the question of their durability and efficiency remains to be tested by the experiment. The experiment is also to be tried for a short distance westward, as far as Seventeenth street, the unsightly wires on the treasury building, executive mansion and war and navy department buildings having all been peremptorily ordered off by the new officials. Quite a large number of these wires belong to the Chesapeake and Potomac Telephone Co., and they too are burying their wires as rapidly as possible. On this route they will have 350 wires laid, extending as far as Twenty-second street. Their 450 wires to M street will be continued by three 50-wire cables to S street. These cables are carried through alleys to the centre of the square or block, where a high pole serves to distribute them to the rear of the customer's premises, thus ridding some of the principal streets of the unsightly poles which have grown to be a regular nightmare to our fastidious triumvirate, who regard with a jealous eye anything that militates against the beauty of the streets of the national capital. They seem impressed with the idea that theirs is a national trust, and nuisances that might, for the public convenience, be tolerated in other and busier cities, can find no lodgment here. By the arrangements above noted some 300 10, 20 and 50 wire poles, with their immense cross-arms, disappear from the business centre of the city, to say nothing of the end to the horrible disfigurement of the above-named public buildings, which rank next to the capitol in cost and magnificence.

A year or two ago the Washington Telephone Co. was started here as a branch of the Pan Electric Co., using the Rogers' telephone, of which Attorney-General Garland, Senator Harris, Hon. Casey Young, of Tennessee, and Gen. Jos. Johnston are directors. The branch company controls the patent for the District of Columbia, Maryland and Delaware. It has done but little business here, but considerable in Baltimore and other parts of Maryland. It has recently received some financial and business reinforcements.

The United States Electric Light Co. continues its negotiations and investigations as to the enlargement of its plant, but has reached no definite action. One suggestion is the location at Georgetown, where the waste water of the canal can be utilized for motive power. To this comes the objection that a full steam-power outfit will also be required to meet emergencies when the canal is frozen or drawn off, or the supply reduced by drought and low water in the river above. Another suggestion is a consolidation with the Brush-Swan company, which is now under consideration by a joint special committee of the two companies. The latter has an extensive plant near the capitol now idle, which could be readily utilized, and at a small expense be so applied as to double the present capacity of the United States company. This, with the Thomson-Houston lights previously spoken of, would doubtless supply any demand likely to arise in the near future.

Col. Whitney, who controls the delivery of the Western Union messages in Washington, has, in order to expedite the delivery of long-distance messages, trained six or eight of his messengers to be expert bicyclists, and they now mount their "fiery steeds" and fly over the concrete streets with their despatches, almost annihilating space. Not all the streets are yet concreted, but the boys know which are, and by a slight diversion can always secure a smooth route. The only drawback to this mode of delivery is the frequent break-downs of the fragile machines, and the incidental delay and cost for repairs.

Digitized by Google

The feeling of hostility to overhead wires which has been so sedulously cultivated by the authorities and the press of this city, is now reacting to the annoyance of the former. The citizens on the route of the proposed new Western Union air line, on Seventh street, from New York avenue, where it takes up the cables, to boundary, finding remonstrance and memorials fruitless, yesterday filed a bill in equity against the company and the commissioners to stop the erection of poles and wires on that street. Judge Hagner set the matter down for a hearing June 3d, and ordered the defendants to show cause why an injunction should not issue.

WASHINGTON, May 20, 1885.

PHILADELPHIA.

The Pennsylvania Legislature Still Working at the Underground Bills.—More Permits Asked for in Philadelphia.—More Infringements of the Bell Patent.—The Baltimore and Ohio Company Outgrowing its Quarters—A New Time-Ball.

OUR legislators at Harrisburg are still tinkering away at the "underground" question, and they no doubt keep the different companies, or their lobbyists, in hot water a great portion of the time when this all-absorbing question is under consideration. A bill introduced by Mr. Reyburn has passed a second reading, compelling all telegraph, telephone and electric light companies to place their wires beneath the surface of mother earth within six months after notification to do so.

The Electrical Committee of City Councils yesterday favorably recommended the ordinance granting leave to the Thomson-Houston Electric Light Co. to extend its lines by erecting poles and wires on Girard avenue, from Franklin to Twelfth, and Spring Garden street, from Sixth to Broad. It was agreed to recommend the granting of permission to lay an underground electric light wire from the *Ledger* building, along the south side of Chestnut street, to the new bank building of Drexel & Co., at the corner of Fifth street. The ordinance granting permission to the Kensington Electric Light Co. to erect poles and run wires on Frankford avenue, from Girard to Lehigh avenues, and on Second street, from Master to Fourth, occasioned a brief discussion, in which Chief Walker, of the Electrical department, took occasion to say there was no room for any extra poles or wires on the streets named. The subject was referred.

The Bell Telephone company do not seem to be very slow in proceeding against those persons who are supposed to be infringers of their patents. They have again brought suit in the United States Circuit Court in this city against William C. Harris, Jr., and Edward Anschultz, alleging that in the manufacture of telephones, they had infringed upon patents granted to Alexander Graham Bell and asking the court to enjoin the defendants from making the alleged infringement. The case will be heard upon argument.

I understand from undoubted authority that the Baltimore and Ohio company is negotiating for more roomy quarters, the present main office being entirely inadequate, owing to the large increase in business. They are so cramped at present that they have been compelled to place some of their instruments on the sides of the room.

The Hydrographic office has placed a time-ball upon the roof of the Maritime Exchange building, at No. 131 South Second street. It will be hoisted about five minutes before noon to the top of the staff. At precisely 12 o'clock, mean time, 75th meridian, the ball starts to drop. The dropping apparatus is connected directly over the wires of the Western Union Telegraph Co. with the United States Naval Observatory at Washington, D. C. If for any reason the ball fails to drop, it will not be lowered until after 12.30 P. M.

SAN FRANCISCO.

Working of the Block Signals.—A Time-Ball for Telegraph Hill.—Wanted, a Pacific Cable.—An Economical Telegraph System Which does not Work.—Hegira of Telegraph Operators from Ogden.—Preparing the Ground for the Opposition.

THE introduction of the block system of signaling was accompanied by two or three collisions and a derailment in the Oakland yard of the Central Pacific R. R. Such results are not unusual upon the introduction of a new improvement of this character, but, now that things are becoming more familiar and the nervousness consequent to beginners at anything has worn off, trains are running regularly and confidently over the network of switches. This climate is particularly adapted to that system. No snow, and very little mud, to interfere with thorough insulation.

We are to have a time-ball on Telegraph Hill in this city, connected by telegraph with the observatory at Mare Island (Vallejo), 30 miles away, which will give us local standard time; this coupled with a "probabilities" bureau of our own, for the Pacific coast, under Lieutenant Craig, demonstrates that we are slowly and steadily forging our way to the important position which this coast should occupy in the commercial world.

What a boon to commerce, and what a source of general satisfaction to the reading people of the world would a cable from the Pacific coast to China be; say along the 40th parallel to the Japanese Islands and Shanghai. In this way we could have pure and unadulterated war news, which must now be taken with considerable allowance after passing through the sieve of a British censorship. This cable was contemplated some eight or nine years ago, and the U. S. Steamer Hassler took soundings, but because it did not promise an abundant return for the money to be expended it was allowed to drop. In a few years when Russia will control the Persian Gulf and the Sea of Oman, she may unite with China in establishing direct cable communication with the Western Hemisphere unless England forestalls her by connecting Victoria, B. C., with Yeddo, Japan. England very seldom unites with other countries in promoting any scheme for the public good unless she is to derive the greatest benefit therefrom.

Mr. Ludwig, a Norwegian, who aspires for fame, has invented a relay which will induce its own current and work 500 mile circuits using but a single cell of gravity battery; he has at least convinced a few monied men in California that he can do so, but he could not convince our chief operator by an actual experiment. Of course he got a current from the cell of battery on a round or metallic circuit to Virginia City but when the wire was grounded at both ends here, the cell at one end and the relay at the other, no current could be induced, hence, I fear he cannot *induce* Mr. Gould to accept his metallic circuit relay, but we thank him for his good intentions and commend his laudable ambition.

Eleven men leave Ogden on the 1st of May, because they are worked 12 and 14 hours per day, and that at 20 per cent. less than under the former manager. The result is the public business is placed at the mercy of the very poorest class of operators, who in fact can neither read copy nor send it decently. This mode of doing business is giving the public an appetite for an opposition when it reaches this coast. The manager at Ogden is a competent, reliable man, but it is evident that he is over-reaching himself in his effort to make a record, and Mr. Dickey ought to know by past experience that poor labor is dearly paid at any salary. Mr. Gamble has as yet kept quiet but I understand the Baltimore and Ohio are pushing on vigorously for El Paso.

BOSTON.

Pavements Left in Bad Condition by Burying Wires.—A Legislative Underground Scheme.—A Deluge of Telephonic Investigation.—The Apportionment of American Electric and Illuminating Co's. Stock.—Electric Light Wires set Fire to Foliage.—An Electric Train Signal.—Electricity at the Society of Arts.—Economical Mill Lighting.

THE Boston *Evening Transcript*, a paper which has said more in its columns in favor of putting electric wires underground than any other, and said it too, with as little intelligent comprehension of the subject as could be imagined, recently contained an item which must have slipped in by accident, or in some sane moment. It was to the effect that the granite paving blocks on State street were in a dangerous condition at certain points "the first fruits of putting electrical wires underground," all of the "downtown" streets are paved with granite blocks, and when the *Transcript's* tirades have their full effect perhaps a few more streets will be in a dangerous condition. As horses and pedestrians "don't go that way," it would seem fully as advisable to continue the present *dangerous* condition of things overhead.

Among all the legislative schemes for the regulation of telephone charges, penning up and strangling telephone companies etc., there has appeared only one underground scheme. A Mr. Spaulding has been before the legislature with a desire to secure rights for himself and associates in Massachusetts which electrical companies may avail themselves of, for a consideration. I understand Mr. Spaulding's patents have not yet been issued, and that he claims to have a large number of applications pending there, which cover all the various points necessary in an underground system for electrical wires. "Reference to the next legislature" was the report of the Mercantile committee on laying electric wires underground.

The legislative committees are still struggling over the various telephone bills.

"An act to prevent discrimination by telephone companies," has been reported favorably by the committees on mercantile affairs and on the judiciary, to the legislature.

The examinations of witnesses by the committees have been interesting, but have not developed anything very new or startling. It is expected that reports will be made this week upon all the telephone matters—and rumors prevail that the committee stands 6 to 5 against allowing the increase of capital, 8 to 3 against state supervision of telephone companies, with minority reports.

Digitized by Google

By the terms of a circular recently distributed among the stockholders, the stock of the American Electric and Illuminating Co. is made exchangeable in the stock of the American Electric Manufacturing Co., of New York, a new company which succeeds, in a larger field, to the business of the corporation first named. The basis of exchange is par for the preferred stock, $3 per share for the common stock. par being $10 in both cases. The new company has made a definite alliance with the Edison company, as I stated in a previous letter.

The electric light wires at Norwich, Conn., indulged in a little playfulness on the evening of the 8th inst. The wires passing through Franklin square touched the large elm trees; a lively blaze was the consequence. Accidents of this character make householders nervous about wires.

On the 15th inst. the Judkins railway train signal was exhibited on the Boston and Providence railroad, a special train being arranged to show the signal to a large party of railroad men. The experiments were most satisfactory. The device is intended to take the place of the bell rope now in use on passenger trains. The following is a general description of the system: An open circuit battery is located at some convenient place on the locomotive from which runs an insulated wire, permanently attached to each passenger coach, and being coupled between the engine and each coach with the automatic coupler. At convenient points in each coach are push knobs for the purpose of transmitting to the engineer any desired signal—to start, stop or back the train. Leclanché batteries are used; this apparatus has been used on the Maine Central and Eastern railroad for a period of six months. It is now used on a regular Boston and Providence train.

On the 9th of April was held the 331st meeting of the Society of Arts, at the Institute of Technology. Prof. C. R. Cross described and exhibited some new apparatus for studying telephone currents. Mr. Geo. W. Blodgett, then explained Boynton's train indicator, designed to be used at railway stations to indicate the time at which a train will leave, and the station at which it will stop.

Col. Livermore, of the Amoskeag Mills at Manchester, N. H., finds that his electric lighting plant gives him a superior service at a price equivalent to 85 cents per 1,000 feet for gas. Comparing this with even the present reduced prices at $1.30 for street gas in Boston proper, and $1.85 to $2.00 in the suburbs, the price appears to be entirely favorable to electricity. But the amount of light required in a mill is much greater than allowed to obtain in the streets. In the weaving rooms of the Amoskeag mills the arc lamps are so numerous that not one of them casts a shadow; and an average of 7.14 hours of light per carbon are obtained, which is a longer period than usually required in mills. In Boston the lights are employed from 7½ to 13½ hours of the day—as for instance in December 13½ hours, and in June and July 7½ hours. To carry the comparison between the illumination of interiors and streets further, it costs more for the latter as they employ long circuits necessitating increased cost for power.

BOSTON, May 19, 1885.

ELECTRICAL NEWS AND NOTES.

OPINION OF THE SUPREME COURT IN THE ELECTRIC RAILROAD SIGNAL CASE.

DECIDED MARCH 30, 1885.

THE decree of the Circuit Court dismissing a bill in equity for an injunction to restrain infringement of letters patent issued July 1, 1873, to F. L. Pope, for an improvement in circuits for electric railroad signals, is affirmed for the following reasons:

1. The patent is for a new combination of old devices. The object of the combination is the accomplishment of a particular result,—to work electric signals on the block system by means of circuits operated by a single battery instead of many. But the thing patented was the particular means devised by the inventor to accomplish that result, and to constitute in this case identity of invention, and therefore infringement, the result, the elements or their equivalents, and the combination must be the same, so that each element shall perform the same function.

2. In the complainant's patent insulated sections of rails as circuit-closers, constitute an essential element of the combination. The statement in the specification that the patentee does not desire to confine himself to the particular devices described for closing the electric circuit, does not permit him to cover, as an equivalent, other forms of circuit-closer, whether before known, or thereafter invented, which would serve the same purpose in the combination.

3. The complainant's patent being for a new combination of old elements, in which a system of branch circuits of equal resistance constitutes one of the ingredients, the particular method in which the resistance of these circuits is equalized is an essential part of the invention. In the complainant's plan the circuits are normally unequal in resistance, and require to be adjusted to an equality in setting up the apparatus, while in the defendant's plan, the circuits are normally equal and do not require equalizing. This introduces new elements, a new combination and a new result.

Appeal from the Circuit Court of the United States for the District of Connecticut.

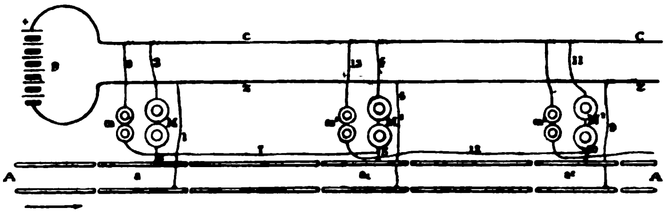
Mr. Chas. E. Perkins and *Mr. Geo. H. Christy* for the appellant.

Mr. S. E. Baldwin for the appellee.

Mr. Justice MATTHEWS delivered the opinion of the Court.

This is a bill in equity for an injunction to restrain the alleged infringements of Letters Patent No. 140,536, for an improvement in circuits for electric railroad signals, issued July 1, 1873, to Frank L. Pope, of whom the appellants, who were claimants below, are assignees. On final hearing the bill was dismissed by a decree now brought here for review by this appeal.

The drawing which accompanies and illustrates the patent is as follows:



The following is the substantial part of the specification, together with the claims:

My invention consists in a peculiar arrangement of electric circuits, in combination with a battery, and with two or more circuit-closers operated by moving trains or otherwise, whereby a series of two or more visual or audible signals situated at intervals along the line of a railroad may be operated by currents of electricity derived from a single battery, thereby obviating the inconvenience and expense of employing, as heretofore, one or more separate batteries situated at or near each signal for the purpose of actuating the same.

In the accompanying drawing, A A represents a portion of the track of a railroad. At intervals of, say, a mile, more or less, sections of the said track, a a^1 a^2, are electrically insulated from the remainder in a manner well understood, and therefore requiring no detailed description. B is a galvanic battery of any suitable construction, and placed in any convenient location near the line of the railroad. Two wires or other conductors, C and Z, are attached to the positive and negative poles, respectively, of the battery, B, and extended to any required distance in a direction parallel or nearly so to the line of the railroad. The conductors, C and Z, may be placed on poles, and should be suitably insulated from each other and from the earth. The conductors, C and Z, are virtually prolongations of the positive and negative poles of the battery, B. Each of the insulated sections of track, a a^1 a^2, &c., is placed at some point at or near which it is desired to erect a signal, and any required number of these may be employed to meet the requirements of any particular case. M, M^1 and M^2 are the electro-magnets which actuate or display the respective signals. The said signals may be of any suitable construction, and should be provided with some suitable means of retaining them in position or action after the circuit through the magnets, M, M^1, or M^2, has been interrupted. The magnets, m, m^1 and m^2, are so arranged as to release, reverse or stop the action of said signals, which have previously been brought into action by the magnets, M, M^1 and M^2.

The operation of the apparatus is as follows: Suppose a train moving along the track, A A, from left to right, in a direction indicated by the arrow. Upon reaching the point, a, the wheels and axles of the train will form an electrical connection between the opposite insulated rails, and a circuit will be formed between the conductor, C, and the conductor, Z, traversing wires 1 and 2, magnet M and wire 3, and the signal attached to M will consequently be displayed. Upon the arrival of the train at a^1 the same operation will be repeated, and another connection formed between C and Z, traversing the wires 4 and 5, magnet M^1 and wire 6, while at the same time a portion of the current will traverse the branch wire 7, magnet m and wire 8. Thus the signal attached to M^1 will be actuated, and simultaneously the action of the magnet m will release or reverse the action of the first-mentioned signal. Upon reaching the point, a_2, the closing of the circuit by the train will in like manner cause the signal attached to M^2 to be displayed, and the signal last displayed by M^1 to be withdrawn. In this manner any required number of such signals may be operated by means of a single battery.

The respective resistances of the several circuits should be so adjusted that they will be as nearly as possible equal to each other, as a much more perfect action of the apparatus will be secured thereby.

On a railroad having a double track two separate series of signals, one series for each track, may be connected with the conductors, C and Z, of a single battery, if required. If preferable, they may be also operated by means of separate batteries and separate conductors.

In cases where it is required to operate a large number of signals extending along the road for a distance of many miles, the two conductors, C and Z, may be extended the entire distance, and a number of batteries attached at convenient intervals—say, for instance, from five to 10 miles apart. The several batteries should all be placed with their positive poles in connection with the wire C, and their negative poles in connection with the wire Z, when they will virtually form one large battery, and the principle of operation will remain the same as that hereinbefore described.

I do not desire to confine myself to the use of any particular form of visual or audible signals, nor to the particular devices herein described for closing the electric circuit at points from which a signal is to be operated. Instead of the circuit being closed automatically by the train itself, it may be closed by a signalman by means of a key or switch, or otherwise.

I claim as my invention—

1. The battery B, in combination with the positive and negative conductors, C and Z, two or more electro-magnets, M M^1 M^2, for actuating, or causing to be actuated, visual or audible signals, and two or more circuit-closers, a a^1 a^2, placed at intervals along the line of a railroad, substantially as and for the purpose specified.

2. The battery B, in combination with the positive and negative conductors, C and Z, two or more electro-magnets, m m^1 m^2, for releasing or reversing visual or audible signals, and two or more circuit-closers, a^1 a^2, placed at intervals along the line of a railroad, substantially as and for the purpose specified.

3. The combination of the battery B. conductors C and Z, circuit-closer a and electro-magnet M, for actuating a visual or audible signal, with the circuit-closer a^1, wires 5, 7 and 8, and electro-magnet m, for reversing, releasing, or stopping said signal, substantially as specified.

Among the several defenses set up in the answer, the two chiefly relied on were: first, that Thomas S. Hall, and not Pope, the patentee, was the first inventor of the improvement claimed; and, second, that the devices used by the defendants were not an infringement of the patent.

The decree below was based on the first of these defenses alone, the Circuit Court finding that Hall was entitled in law to priority of invention; but we have not found it necessary to dis-

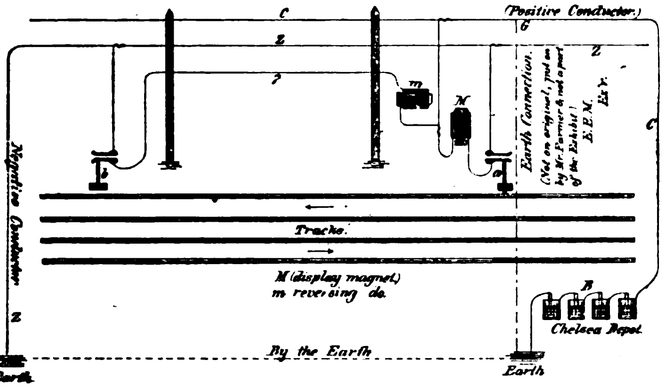
cuss the questions of fact and law embraced in this issue, as we have concluded to dispose of the case upon the ground that the defendants did not, by the devices used by them, infringe the patent of the complainants.

These devices are illustrated by a drawing, of which the following is a copy:



This diagram represents the plan of electric railroad signals placed and put in practical operation by the defendants on the line of the Eastern railroad, near Boston, prior to the bringing of this suit. In comparing it with the drawing annexed to the patent, it is to be remembered that the latter represents a series of double signals in succession on the line of a railroad track divided into blocks, while Exhibit C represents but one pair of such signals in one such block. To make it correspond with the other, as a representation, it should be imagined as being repeated in several successive blocks, constituting portions of one circuit, closed at fixed points by circuit-closers for that purpose.

Mr. Pope, the patentee, drew this diagram, and, as a witness on behalf of the complainants, explains it, in comparison with the plan described in the patent, with a view to establish their identity. He says:

I have made a diagram which exhibits the apparatus which I examined, or so much of it as is material to this case, which I annex, and is marked "Exhibit C." A battery of, perhaps, 100 cells is placed in the station building at Chelsea. One pole of this battery—I think the negative pole—is connected to the earth. A conductor is attached to the other or positive pole of the battery, consisting of an insulated wire extending along parallel with the track upon poles. This wire, which I examined, extended toward Boston, the end remote from Chelsea being disconnected, or, as it is termed, "open." A second conductor, consisting of another similar wire insulated and attached to the same poles, was arranged parallel to the first one. The second wire was open at Chelsea, and connected with the earth at its remote end. The first-mentioned wire I have shown in the diagram, and marked "positive conductor." The second wire is marked "negative conductor." At a short distance from the station a semaphoric signal is placed, consisting of a red disc balanced upon a lever. This was placed in the cupola of a small building at the side of the track. An electro-magnet was arranged, with its armature attached to said lever, so that when brought into action the red disc on the other end of the lever would be moved into a position to render it visible through an opening in the cupola. A latch or detent was placed in a position to fasten the lever after the action of the magnet had ceased, and thus continue the exhibition of the signal. A circuit-closer was placed upon the track at a point near the signal, which consisted of a lever so placed as to be depressed by the wheels of a passing train, which movement caused the circuit to be closed by pressing two springs together. When the circuit was thus closed by a passing train, a connection was formed between the positive and negative conductors, and the electric current in passing from one to the other passed through and operated the magnet by which the signal was displayed. At a point, perhaps, a mile distant, another signal was arranged in precisely the same manner in connection with a second circuit-closer, and the same positive and negative conductors. An additional circuit-closer, placed upon the track in the vicinity of this last-named signal, was arranged to form a connection from the positive to the negative conductor by the way of a third wire running upon the poles back to the signal first mentioned, where it passed through and operated a second magnet, which lifted the latch or detent and allowed the disc to return to a position concealing it from view. I examined two of these signals, and saw many others along the line of the road. I find in this arrangement thus described the combination claimed in the first claim of said patent, consisting of a battery, in combination with positive and negative conductors, two or more electro-magnets for operating visual signals, and two or more circuit-closers placed at intervals along the line of the railroad; also, the combination claimed in the second claim of the patent, consisting of a battery, in combination with positive and negative conductors, two or more electro magnets for reversing visual signals, and two or more circuit-closers placed at intervals along the line of the railway. I also find the combination claimed in the third claim of a battery, positive and negative conductors, a circuit-closer, and electro-magnet for actuating a signal, with a second circuit closer, wires, and a magnet for reversing said signal.

Mr. Moses G. Farmer, an expert witness on behalf of the complainants, makes the same comparison, with the result, according to his opinion, of establishing that the defendants' system is essentially the invention described in the patent. On the other hand, Professor Henry Morton, an expert witness on behalf of the defendants, points out two particulars in which the plan, as practiced by the defendants and shown in Exhibit C, differs from that of the Pope patent so materially that they cannot be considered substantially the same. The first of these is that in the patent, insulated sections of the railroad track, used when covered by a locomotive or cars as a circuit-closer, are made essential to the combinations claimed, while they are dispensed with in the Hall system, other and independent circuit-closers being employed. The second is thus described by Professor Morton in his testimony:

I also find a difference between the plan described in the patent and that shown in Exhibit C in another regard. In the plan of the patent the conductors c and z are connected respectively with the positive and negative poles of the battery, or, as the patent itself states, "are virtually prolongations of the positive and negative poles of the battery."

In the plan shown in Exhibit C, however, the conductor c, or positive conductor only, is connected with the battery, the other conductor, z, or, as it is called, "negative conductor," having no connection with the battery. In consequence of this difference of arrangement in the system of the patent, the positive conductor, c, carries the positive current in one direction away from the battery, and the other or negative conductor, z, brings the positive current in the opposite direction, or back to the battery; and thereby involves the production of circuits of different resistance for each station. In the system represented in Exhibit C, on the other hand, both the conductors, c and z, serve to carry the positive current in the same direction away from the battery, and should, therefore, properly be called "positive conductors." As a result of this arrangement, the current always passes through the same or equal circuits, no matter at which station the connection is made, simply changing from one to the other of these equal parallel wires at the station where the contact is effected. It is for this reason that in this system no equalization of resistance, in the sense involved in the description of the patent, is required.

It is upon these two points that the question of infringement depends. In considering them, it is important to bear in mind that the patent is for a combination merely, in which all the elements were known and open to public use. No one of them is claimed to be the invention of the patentee. He does not claim them himself as separate inventions. It is simply a new combination of old and well-known devices for the accomplishment of a new and useful result that is claimed to be the invention secured by the patent; and the well-settled principles of law, heretofore applied to the construction of patents for combinations merely, must apply and govern in the present case. The object of the patented combination was the accomplishment of a particular result—that is, to work electric signals on what was known as the "block system," by means of circuits operated by a single battery instead of many; but this result or idea is not monopolized by the patent. The thing patented is the particular means devised by the inventor by which that result is attained, leaving it open to any other inventor to accomplish the same result by other means. To constitute identity of invention, and therefore infringement, not only must the result attained be the same, but in case the means used for its attainment is a combination of known elements, the elements combined in both cases must be the same, and combined in the same way, so that each element shall perform the same function; provided, however, that the differences alleged are not merely colorable, according to the rule forbidding the use of known equivalents.

The first question we have to consider upon the issue as to infringement is whether insulated sections of the rails as circuit-closers constitute an essential element in the combinations described in the patent; and that question we are constrained to answer in the affirmative. These insulated sections of track are shown and marked on the drawing which accompanies the specification, and in its descriptive part they are referred to as parts of the arrangement. It says:

At intervals of, say, a mile, more or less, sections of the said track, a a^1 a^2, are electrically insulated from the remainder in a manner well understood, and therefore requiring no detailed description.

And again:

Each of the insulated sections of track, a a^1 a^2, is placed at some point at or near which it is desired to erect a signal, and any required number of these may be employed to meet the requirements of any particular case.

And, in describing the operation of the apparatus, it further says:

Upon reaching the point, a, the wheels and axles of the train will form an electrical connection between the opposite insulated rails [&c.]. Upon reaching the point a^2, the closing of the circuit by the train will in like manner cause the signal attached to M^2 to be displayed, and the signal last displayed by M^1 to be withdrawn.

It is true that the patentee also says in the specification:

I do not desire to confine myself to the use of any particular form of visual or audible signals, nor to the particular devices herein described for closing the electric circuit at points from which a signal is to be operated;

but that he does not thereby indicate any intention of dispensing with insulated sections of the track as a necessary part of the mode of forming and closing the circuit appears from what immediately follows:

Instead of the circuit being closed automatically by the train itself, it may be closed by a signalman by means of a key or switch, or otherwise.

This language evidently implies that the insulated sections of the track are constant factors in the plan, the only alternatives proposed having reference, not to a substitute for them, but merely to another mode of using them in closing the circuit. So in each of the three claims, the circuit-closers, a a^1 a^2, or one or more of them, are expressly named as part of the combination claimed as the invention of the patentee. The use of insulated sections of the railroad-track thus repeatedly appears in every part of the specifications as an unchangeable and characteristic feature of the invention, and there is nothing in the state of the art at that date, as disclosed in the evidence, to show that the patentee would have been justified in applying, or that, if he had applied, an application would have been sanctioned by a grant of a patent for a combination as large and undefined as that now

Digitized by Google

claimed by implication and construction, so as to cover every form of a circuit-closer then known or thereafter invented; for that employed by the defendants as part of the Hall system was not only not known and in use at the date of the patent, but was a device invented by Hall himself, or one by Snow, for which the latter obtained a patent dated October 21, 1873. It dispenses altogether with the use of insulated sections of the track, and employs instead a separate instrument placed near the track, and worked by means of a lever connected with the track, so that the wheels of locomotives and cars passing on the track depress the outer end, the lever being raised again and held up after the train has passed by means of a spring, which holds it in place. Upon this point the case seems to fall clearly within the rule declared in *Prouty* v. *Ruggles* (16 Peters, 336); *Silsby* v. *Foote* (14 How., 217); *McCormick* v. *Talcott* (20 How., 402); *Vance* v. *Campbell* (1 Black, 427); *Eames* v. *Godfrey* (1 Wall., 78); *Dunbar* v. *Myers* (94 U. S., 187); *Fuller* v. *Guetzler* (94 U. S., 288); *Imhauser* v. *Buerk* (101 U. S., 647); *Gage* v. *Herring* (107 U. S., 640); *Seymour* v. *Osborne* (11 Wall., 516); *Gould* v. *Reese* (15 Wall., 194); *Gill* v. *Wells* (22 Wall., 1); *McMeenay* v. *Mallory* (111 U. S., 97); *Fay* v. *Cordesman* (109 U. S., 408).

On the second branch of the issue as to infringement, we think the case is quite as clearly for the defendants. In the patent the entire circuit operated by the single battery, and which is closed at intermediate points for the purpose of displaying and concealing the signals, is described as formed by means of two wires or other conductors, C and Z, attached to the positive and negative poles of the battery, extended to any required distance in a direction parallel, or nearly so, to the line of the railroad. These wires may be placed on poles, it is said, and should be suitably insulated from each other and from the earth, and they are declared to be virtually prolongations of the positive and negative poles of the battery. Throughout, the two conductors are designated as metallic, and insulated from the earth, and they are embraced under that description in each of the claims. On the other hand, the defendants' plan does not include a metallic circuit composed of two conductors, as thus described, but uses a circuit composed in part of the earth itself. The material difference in the principle or mode of operation of the two plans, as distinguished in this particular, is indicated by Professor Morton in the extract from his testimony already quoted. It will become more apparent on further explanation.

The object proposed by the plan of the patent is to operate with one battery instead of several along the line of a railroad an electric circuit of considerable length, divisible into a number of subsidiary circuits, for the display of signals at many stations by means of circuit-closers operated automatically by passing trains in definite and predetermined succession. It is obvious that the battery must have sufficient power, being placed at one end of the entire circuit, to operate efficiently at the other extremity. The force necessary for that purpose would be much greater than would be needed for the subsidiary circuits, all of which, it will be observed, are different in length; and this difference of force in the battery might be so great, owing to the required length of the whole circuit, as, when expended upon a shorter intermediate circuit, to destroy its capacity for working the signals by overheating. It becomes, therefore, a matter of importance in some way to equalize the resistance of these varying circuits. The patent itself contemplates this necessity, and undertakes to make provision for it. It is said in the specification that—

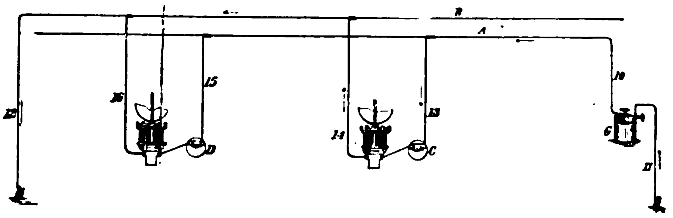
The respective resistances of the several circuits should be so adjusted that they will be as nearly as possible equal to each other, as a much more perfect action of the apparatus will be secured thereby.

The specification does not point out any particular methods for that purpose; but it is stated in the evidence of experts that such means were well known at the time and in common use—such as by varying the dimensions of the wire on the magnets, or the introduction of resistance-coils into the nearer circuits. These devices would be independent of the apparatus described in the patent, and would have to be adjusted to the peculiar situation of each line of signals in practical use. In the Hall system, as used by defendants, no such necessity exists. According to that plan, there is no necessity of equalizing the resistance of the several sub-circuits, for they are all exactly equal by their construction, as the electric fluid, in working the signal at any point, when a sub-circuit has been formed by a circuit-closer, nevertheless traverses the whole extent of the large circuit, and returns by means of the connection formed by the earth to the battery. So that in effect the Hall plan forms its apparatus, counting the connection through the earth, as though it were a continuous wire, as it might be, by means of three lines of conductors, of which two are combined by connecting wires with the magnets which operate the signals at points where the circuit is closed for that purpose, carrying the positive electricity throughout the whole distance to the extreme point of the entire circuit, and then returning it by the third line, which is the connection by means of the earth; and, inasmuch as a wire might be used for this purpose instead of the earth, it would then show three metallic conductors; and Mr. Farmer, the complainants' expert, is quite right in saying, as he does, that the equalization of the resistances in the several sub-circuits, accomplished in the plan of Hall—

is due to the arrangement of the wires wholly, and not at all to the fact that the earth is used as a portion of the conductor.

This arrangement is altogether unlike that of the patent. It introduces into the plan of the defendants new elements, a new combination and a new result. The two wire conductors are not the same, for in the patent one conducts positive electricity, the other returns the current and completes the circuit, while in the other both the metallic conductors carry the current forward while the earth returns it, and in this mode the desideratum is obtained of securing equality of resistance by making all the circuits equal in size.

The device cannot be regarded as a substitute or an equivalent for anything contained in the complainants' patent. It is of itself an independent invention, and as such forms the sole subject of a patent granted to Hall and Snow, July 13, 1875. To explain more satisfactorily the mode of its operation, so as to show that it differs substantially from the arrangement of the complainants, the descriptive parts of the Hall and Snow patent and the attached drawings are here given:



In the drawing the letters A B designate two wires which extend along the line of a railroad track, or, in other words, form the line wires of a telegraph line. The wire A connects by a wire, 10, with one—say, the positive—pole of a galvanic battery, G, and the other pole of this battery connects by a wire, 11, with the ground. The battery, G, is supposed to be situated at one end of the line, and at the opposite end of said line the wire, B, is made to connect by a wire, 12, with the ground. Along the line are distributed a series of keys or circuit-closers, C D, each of which is connected with the line wires, A B, the connection of the circuit-closer, C, being effected by wires 13 and 14, and that of the circuit-closer, D, by wires 15 and 16. If the circuit is closed through the circuit-closer, C, the current passes from the battery through wire 10, line wire A, wire 13, circuit-closer C, wire 14, line wire B, and wire 12 to the ground, and through the ground and wire 11 back to the battery. If the circuit is closed through the circuit-closer D, the current from the battery passes through wires 10, A, 15, circuit closer D, wires 16, B and 12 to the ground, and through the ground and wire 11 back to the battery.

From these two examples it will be seen that whenever the circuit is closed along the line the electric current has to traverse the whole circuit, and consequently the resistance is the same in all cases.

It thus clearly appears that the difference in this particular between the invention claimed by the complainants and the alleged infringement is a difference in the arrangement of the parts and in the principle of the combination, with different elements performing different functions; and that the difference is something more than the mere substitution of a connection by means of the earth for one of the conducting wires. The case is, therefore, clearly distinguishable from that of *The Electric Telegraph Co.* v. *Brett* (10 Com. Bench, 838), cited and relied on by counsel for the appellants as in point, where the substitution of the earth for a wire as a conductor, being the sole difference, was held, under the English patent laws, not to be sufficient to destroy that identity between the two competing devices which constituted in that case the infringement alleged, although the patent itself called only for metallic conductors. Were that the only difference between the two plans under examination in the present case, there might still be question, in view of our own patent laws, whether the patentee has not made a wholly metallic circuit a necessary part of his combination, to be determined by considerations which we have not thought it necessary to bring into view as bearing upon that point, for, as we have seen, the difference on which we ground our conclusion that the defendants are shown not to have infringed the complainants' patent in this particular is not merely that they have used the earth for the return of the current that completes the circuit, instead of a metallic conductor, but that they have arranged their conductors in reference to the battery, the magnets, the rails and the earth, upon such a system and with such relations and connections that in operating their signals by a single battery the circuits are equalized as to resistance, while in that of the plaintiffs the circuits are of unequal size and resistance, requiring for successful practical use the equalization of the resistances thus created by means of independent and additional devices. One plan proceeds upon the idea of unequal circuits to be afterward equalized; the other adopts and embodies the idea of avoiding the necessity of subsequent rectification by an original adjustment of equal resistances. The difference is inherent in the two combinations and is substantial.

On the ground that in the two points mentioned the defendants' system of signaling is shown not to be an infringement of that described in the patent of the appellants, the decree of the Circuit Court dismissing the bill is affirmed.

THE SAWYER AND MAN PATENT FOR INCANDESCENT LAMPS.

UNITED STATES PATENT OFFICE.

William Edward Sawyer, of New York, and Albon Man, of Brooklyn, N. Y., Assignors to Electro-Dynamic Light Company of New York.

ELECTRIC LIGHT.

Specifications forming part of Letters Patent No. 317,676, dated May 12, 1885. Application filed January 9, 1880.

To all whom it may concern:

Be it known that we, William E. Sawyer, a resident of the city, county and state of New York, and Albon Man, a resident of Brooklyn, in the county of Kings and State aforesaid, both citizens of the United States, jointly have invented certain new and useful improvements in electric lamps, of which improvements the following is a specification.

Our invention, speaking generally, relates to that class of electric lamps employing an incandescent conductor inclosed in a transparent hermetically sealed vessel or chamber, from which oxygen is excluded, and constitutes an improvement upon the apparatus shown in letters patent No. 205,144, granted to us June 18, 1878.

Our invention relates more especially to the incandescing conductor, its substance, its form, and its combination with the other elements composing the lamp. Its object is to secure a cheap and effective apparatus; and our improvement consists, first, of the combination, in a lamp chamber composed wholly of glass, as described in patent No. 205,144, of an incandescing conductor of carbon made from a vegetable fibrous material, in contradistinction to a similar conductor made from mineral or gas carbon, and also in the form of such conductor so made from such vegetable carbon, and combined in the lighting circuit within the exhausted chamber of the lamp.

Fig. 1.

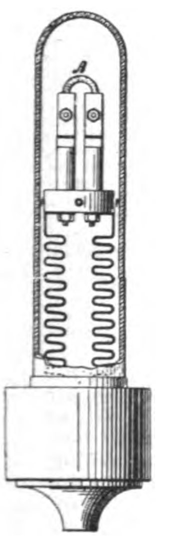

Fig. 2.

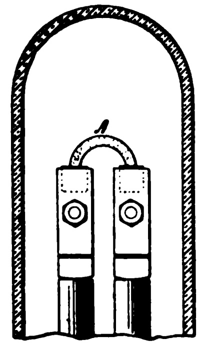

Fig. 3.

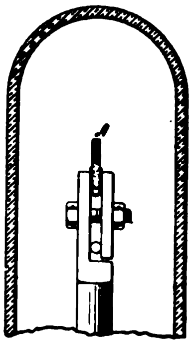

Fig. 4.

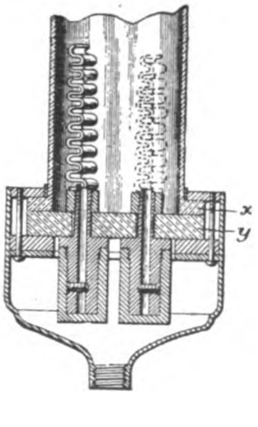

Fig. 5.

The accompanying drawings show all our improvements embodied in an apparatus or lamp substantially like that represented in the patent above referred to, being the form in which we have practically used it; but some of our improvements may be used in connection with other forms of lamps with equally good effect.

Reference being had to said drawings, figure 1 is a top view of the lamp; figure 2, a side elevation thereof; figure 3, a side view in elevation of the burner on an enlarged scale to show its details more clearly, and figure 4 is a similar edge view.

Figure 5 of the drawings shows a vertical section through the bottom of the lamp. In this figure x is a glass flange on the bottom of the lamp chamber; y is a glass disc corresponding in size to the flange, and is ground to the bottom thereof to form an air-tight joint, so that the entire wall of the chamber is formed of glass, the electrodes passing through the glass disc in the manner shown to form the lighting circuit in the chamber, substantially as in said patent No. 205,144. The sealing of the electrodes, where they pass through the glass wall, is done with any suitable cement, or in any of the well-known methods of sealing glass upon metal electrodes previous to the filing of this application.

The electric connections of this lamp are made in the base thereof, substantially the same as in our patent No. 210,809, dated December 10, 1878, and the whole bottom is inclosed in a cup filled with wax or other suitable cement, the same as in that patent, the cement sealing in this lamp being also applied in substantially the same way as in the patent last above mentioned, the invention making the subject matter of this application being improvements upon the lamps described in the patents above referred to, to the extent of the claims making part hereof.

In the practice of our invention we have made use of carbonized paper, and also wood carbon. We have also used such conductors or burners of various shapes, such as pieces with their lower ends secured to their respective supports, and having their upper ends united so as to form an inverted V-shaped burner. We have also used conductors of varying contours, that is, with rectangular bends instead of curvilinear ones; but we prefer the arch shape.

No especial description of making the illuminating carbon conductors, described in this specification and making the subject-matter of this improvement, is thought necessary, as any of the ordinary methods of forming the material to be carbonized to the desired shape and size, and carbonizing it while confined in retorts in powdered carbon, substantially according to the methods in practice before the date of this improvement, may be adopted in the practice thereof by any one skilled in the arts appertaining to the making of carbons for electric lighting or for other use in the arts.

An important practical advantage which is secured by the arch form of incandescing carbon is that it permits the carbon to expand and contract under the varying temperatures to which it is subjected when the electric current is turned on or off without altering the position of its fixed terminals. Thus the necessity for a special mechanical device to compensate for the expansion and contraction which has heretofore been necessary is entirely dispensed with, and thus the lamp is materially simplified in its construction. Another advantage of the arch form is that the shadow cast by such burners is less than that produced by other forms of burners when fitted with the necessary devices to support them.

Another important advantage resulting from our construction of the lamp results from the fact that the wall forming the chamber of the lamp through which the electrodes pass to the interior of the lamp is made wholly of glass, by which all danger of oxidation, leakage or short-circuiting is avoided.

The advantages resulting from the manufacture of the carbon from vegetable fibrous or textile material, instead of mineral or gas carbon, are many. Among them may be mentioned the convenience afforded for cutting and making the conductor in the desired form and size, the purity and equality of the carbon obtained, its susceptibility to tempering, both as to hardness and resistance, and its toughness and durability. We have used such burners in closed or hermetically-sealed transparent chambers, in a vacuum, in nitrogen gas, and in hydrogen gas; but we have obtained the best results in a vacuum, or an attenuated atmosphere of nitrogen gas, the great desideratum being to exclude oxygen or other gases capable of combining with carbon at high temperatures from the incandescing chamber, as is well understood.

The nature of our inventions and the operation of our improved lamp will be readily understood from the foregoing description and the following claims.

We claim as our joint invention:

1. An incandescing conductor for an electric lamp, of carbonized fibrous or textile material, and of an arch or horseshoe shape, substantially as hereinbefore set forth.

2. The combination, substantially as hereinbefore set forth, of an electric circuit and an incandescing conductor of carbonized fibrous material, included in and forming part of said circuit, and a transparent hermetically-sealed chamber in which the conductor is enclosed.

3. The incandescing conductor for an electric lamp, formed of carbonized paper, substantially as described.

4. An incandescing electric lamp consisting of the following elements in combination: first, an illuminating chamber made wholly of glass hermetically sealed, and out of which all carbon-consuming gas has been exhausted or driven; second, an electric circuit conductor passing through the glass wall of said chamber and hermetically sealed therein, as described; third, an illuminating conductor in said circuit, and forming part thereof within said chamber, consisting of carbon made from a fibrous or textile material, having the form of an arch or loop, substantially as described, for the purpose specified.

In testimony whereof we have hereunto subscribed our names this 8th day of January, 1880.

William Edward Sawyer,
Albon Man.

Witnesses:
Wm. H. Church,
Wm. D. Baldwin.

ANNUAL MEETING OF THE AMERICAN BELL TELEPHONE CO.

At the annual meeting of this company held at Boston, March 31st, the old board of officers was re-elected with the exception of Judge Bradley, director, who retires on account of ill health, Mr. Charles E. Perkins being his successor. The annual report of the directors was read, the most important points of which are given herewith.

BOSTON, March 31, 1885.

To the Stockholders:

Telephone business in the year ending Dec. 31, 1884, has shared the dullness which characterized most branches of industry during the same period. Nevertheless, the increase in the number of subscribers and the telephones in use has continued, although at a diminished rate.

The following comparative statement gives the statistics for the year, which are substantially correct, although exact figures in regard to some of the items cannot be insured, as a considerable portion of the properties are not under our direct ownership and control:

EXCHANGES.

	1883.	1884.	1885.	Inc. over 1884.
Exchanges	725	906	764	*142
Branch Offices	345	419	481	62
Miles of wire on poles	....	....	88,441	....
Miles of wire on buildings	....	....	11,886	....
Miles of wire underground	....	....	1,225	....
Total miles of wire	68,571	85,896	101,592	15,696
Total circuits	74,484	97,422	107,268	9,846
Total subscribers	97,728	123,625	134,601	10,976
Total employés	3,716	4,762	5,162	400

EXTRA-TERRITORIAL LINES.

	Jan. 1, 1883.	Jan. 1, 1884.	Jan. 1, 1885.	Inc. in 1884.
Number of lines	247	598	826	228
Miles of pole lines	6,154	29,592	25,766	5,174
Miles of wire	18,658	29,359	35,631	6,274

*Decrease.

Instruments in the hands of licensees under rental: Dec. 20, 1882, 237,728; Dec. 20, 1883, 298,580; Dec. 20, 1884, 325,574; increase during year, 26,994.

The average daily number of exchange connections in the United States is 697,966, or a total number per year of 251,267,760, the subscribers paying, according to the size of the exchange and the character of the service, from 3.1 to 5.7 cents per connection. The average daily number of extra-territorial connections (that is, connections between a resident of one exchange district and a resident of another exchange district) is 7,526, or a total number per year of 2,709,360. Our share of the receipts from extra-territorials and toll business has increased nearly 50 per cent. over the receipts of the previous year. It will be noted that during the year there was a net gain of 10,976 subscribers in the exchanges, with an increase in miles of wire of 15,696. As a rule, all the larger exchanges have a steady growth, and there seems no reason to doubt that this will continue for some time to come. On the other hand, there is a pause in building exchanges in small places, and some 78 of those already started have been for the present given up, while 61 new ones have been established. The establishment of these systems in small towns was probably pushed too rapidly in view of the stagnation in general business which followed. Many of those now abandoned will be restored upon a revival of business, and others can be put into operation under a system which is being worked out for small exchanges without a central office, and which, if as successful as we hope, will carry the telephone into a large number of towns and villages where it is now impossible to place them upon a paying basis. The table shows an apparent decrease of 142 in the number of exchanges reported, but 125 of these have been redistricted as branch offices and are still in operation, while 63 branch offices have become toll stations.

The process of taking the wires from housetops and placing them on pole lines has continued, and now there are in the exchanges 88,481 miles upon poles and only 11,886 miles upon buildings. Great progress has been made in getting the heavy overhead lines into aerial cables in the cities. This is an important step, and one that is materially reducing the unsightliness of the telephone systems, while adding to the safety of the wires and reducing the cost of maintenance. There are now 4,300 miles of wire in 69 miles of aerial cables in use. Some progress has been made in getting wires underground for short distances in the cities, and 1,225 miles of wire underground are now reported. In New York, the legislature, against the recommendation of the Roosevelt committee, to whom the matter was referred, passed an act requiring telephone companies in cities of over 500,000 population—that is, in New York and Brooklyn—to place all wires underground before Nov. 1, 1885. This is wholly impracticable for several reasons. In the first place, no method is known by which entire telephone exchange systems can be worked underground, although for limited distances and in certain localities fairly satisfactory results can be obtained. Even were the methods discovered, part of the wires must be overhead for distribution from central points and for reaching places where subscribers are so few that the cost of going underground would be out of all proportion to the price they could pay. Again, to place even the bulk of the 6,639 miles of wire in the New York and Brooklyn systems underground in one year, would involve the tearing up all at once of most of the streets in those cities, and would not for a moment be permitted. In New York, however, some important underground work will be done this summer, the results of which will possess great interest for our company, and if favorable, we expect to follow them up with extensive improvements in this direction.

* * * * * * *

Nearly all of the licensed companies are in good condition, and many of them continue to pay regular dividends in spite of the general dullness. It has not, however, been a year when new enterprises of any kind could be easily promoted, and, in common with other industries, the telephone companies have found it difficult to sell stock or bonds for their construction purposes. It has been probably as much due to this as to the lessening of the demand for telephone service that our output of instruments has decreased. Most of the companies have met this condition of things by applying their net earnings in part, and in some cases wholly, to their new construction. The result of this conservative policy, although temporarily disappointing to stockholders, has been to materially increase the intrinsic value and earning capacity of the properties, and in view of the importance of an early occupation of the field while numerous infringing claimants were striving to gain a foothold, we have no doubt the policy was the right one. How far it should be continued under the more favorable conditions that now prevail is to be carefully considered by each company.

The amount of net earnings applied to new construction in those of our licensed companies in which we hold stock is stated by our auditor to be $806,633.97, out of a total spent for construction in 1884 of $1,505,907.64.

The absence of revenue to our company from its investment in the New England Telephone and Telegraph Co. is noticeable, and is owing to the fact that we have been obliged to use the net earnings of Boston, which, but for the consolidation of the Boston exchange with several New England companies, would have been a constant source of income to us, in the reconstruction of the exchanges and lines outside of Boston. From this it will be apparent that the charges made against the American Bell Telephone Co. of having gained an advantage over the New England companies by the consolidation, is so far from being true that we have actually lost money by the transaction. The New England company have earned in the year ending Dec. 31, 1884, gross $912,-621.75, and net, $222,441.63, of which $192,098.77 has been spent for construction.

In Canada the Minister of Agriculture has declared the Bell patent void on account of alleged failure to comply with the law requiring manufacture in Canada of patented articles, and with another requiring that such articles shall be offered to the public. The action of the Bell company of Canada in these regards has been taken in accordance with the best legal advice that could be obtained in Canada, and the decision of the minister has occasioned much surprise there. The matter will be carried, if necessary to the Privy Council of England. The infringing company will be at once sued under the other patents owned by the Bell company, and in the meantime the net earnings of the company will have to be used for construction. The company is carefully managed, and its net earnings for the past year have increased to $118,952.-78 on a capital of $1,000,000, and of these earnings $88,951.78 have been spent for construction.

* * * * * * *

The business of the Western Electric Co. has especially felt the effects of the general depression. The gross business for the year ending Dec. 1, 1884, was $1,534,784.04, and the net about $110,000, or 11 per cent. on the capital stock.

The question of how to consolidate its business with advantage is under consideration. Mr. W. S. Smoot, formerly with the Remington Arms Co., has been elected president, and we expect to secure an increase of business with a less expensive system of operation before long. The company has, since October, 1882, put the net earnings into the business, but has just declared a dividend of 1½ per cent—$15,000.

The experimental line between Boston and New York has proved entirely successful. It was built with a metallic circuit of two copper wires (hard drawn No. 12), and was placed upon poles belonging to the several companies occupying the route via Providence. Conversation can readily be carried on in low tones, the speaker's voice being easily recognized. There can no longer be a question of the success of long-distance lines between all points within 200 or 300 miles of each other, and even more, when the demand for such services is of a character to warrant the building of metallic circuit systems. Such systems will be very costly, and our present licensed companies are neither provided with capital nor organized for the purpose of undertaking a work of the proportions which commercial success in this business will involve.

It therefore becomes necessary for one company to take the lead in building lines of connection between the large cities, and

Digitized by Google

a beginning will be made this summer between New York and Philadelphia.

As we have already nearly reached the limit of our authorized capital, it is necessary either to obtain authority for an additional amount or to devise means of raising what may be required in some other way than by an increase in our capital stock. The preference for the latter method, however, being general, we have applied to the Massachusetts legislature for authority to increase our capital to $30,000,000, in order that we may be equipped both for the work just described and for the extensive enlargment of our business in any branches that may appear desirable. It should be understood that it is not proposed to issue any part of this stock except for the development of our business.

As soon as definite arrangements can be made for going forward with the work, the directors will place before the shareholders their programme for such enterprises as it is thought best to undertake this spring and summer.

Among the inventions of the year, that of a new transmitter, by Mr. Francis Blake, is prominent, and most excellent results are hoped for in its adaptation to both long and short lines. We expect to test it shortly in actual use in our own business. Mr. Blake has offered it to the company on terms which are thought favorable, provided the tests result satisfactorily.

* * * * * * *

It is hoped that this year will see the end of the most vexatious and expensive part of our litigation, and that the accumulating decisions of our courts that Bell invented the telephone will enable us to prevail with ease against the infringers in all parts of the country, and will deter capital from investing in infringing companies.

* * * * * * *

In view of the statements which have been circulated that the larger part of the stock of the American Bell Telephone Co. represents merely water, it may be well to recall to the stockholders the fact that out of the $9,602,100 of issued capital stock about $5,000,000 has been paid in cash by the stockholders of the National Bell and American Bell telephone companies, $190,000 represents property taken over by the National Bell Telephone Co. at its organization and $105,000 is still in the treasury, and the balance represents patents. And in addition to the $5,200,000 paid in cash or property, net earnings have been used to the amount of $351,000 in increasing the plant of the company. As showing the magnitude of the telephone business it will be interesting to know that the capital stock of the telephone companies in the United States operating under the Bell patents (omitting the American Bell Telephone Co.) was on Jan. 1, 1885, over $53-000,000. The gross earnings were, partly estimated, over $9,500-000 and the net earnings, partly estimated, $3,450,000, showing a gain over the earnings of 1883, although to what extent it is difficult to say, as some of the companies failed to report the increase, and several have not been in business long enough to be able to furnish the comparison.

At this time, when the question of the rates charged to the users of telephones is being discussed, both in legislatures and by the public, it seems proper to call the attention of the stockholders to a few facts in relation to this subject.

The average cost of a connection to a subscriber varies from $3\frac{1}{10}$ to $5\frac{7}{10}$ cents, as has been previously stated. For this sum the telephone company is obliged to keep at the service of the subscriber a wire, which for a large part of the time is idle; to keep an operator ready to receive his calls at all hours; to maintain his telephone and batteries in good condition; to provide for the rapid depreciation of poles, wires, switch-boards and all the apparatus of the central office, and, finally, to provide all the improvements in apparatus which each year develops, for the public very properly insists on receiving the most efficient service that can be given.

As an instance of the rapid depreciation of property, and of the changes likely to occur in electrical inventions, it may be well to say that the telephone system in Boston has been twice re-built, and the new multiple switch-boards for the Boston office had hardly been received, and had not been put in place, when the invention of an improvement in detail gave such promise of excellent results that the boards were shipped back to Chicago to have the new invention added to them.

The sum then charged to the subscriber does not seem large when the cost of the service rendered by the telephone company is considered. Neither does it seem exceptional, when it is seen what the subscriber receives for his payment of three to six cents. He obtains an immediate conversation with any subscriber to his exchange, a conversation which renders needless the employment of messengers, telegraphs, and even the mail, all of which modes of communication are either slower or more costly, and often both more slow and more costly and less satisfactory than that which is given by the telephone. The subscriber also obtains the privilege of communicating, for a small extra charge, with the subscribers of any exchange in towns or cities within a limited distance from his own. And as the number of subscribers in each exchange increases, and as the distance through which telephonic communication is possible become extended, the advantage to the subscriber is also greatly increased.

Finally, we may continue to hope that, as the season opens and the general business outlook becomes brighter, and as the infringing companies are one by one compelled to acknowledge the validity of the Bell patents, the telephone companies will also share in the returning business prosperity.

The treasurer's report was presented in print. A vote was passed, in conformity with the recommendation of the directors, to increase the capital stock from $9,800,000 to $10,000,000.

STATISTICS OF TELEGRAPH LINES OF THE WORLD.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The annual meeting of this association, for the election of officers, and the transaction of business was held at the house of the American Society of Civil Engineers No. 127 East 23d street, May 19th. The following officers were elected: president, Dr. Norvin Green; vice-presidents, D. H. Bates, Prof. A. E. Dolbear, Francis W. Jones; managers, Charles L. Buckingham, David

Digitized by Google

Brooks, T. C. Martin, George M. Phelps, Jr., Prof. B. F. Thomas, W. D. Sargent; treasurer, Col. Rowland R. Hazard; secretary, Ralph W. Pope. The report of acting secretary T. C. Martin shows that although the Institute has only been in existence one year it has 279 members and associates in all parts of the country. The Institute has as yet no permanent home, but a proposition has been made to have the various scientific and artistic societies of this city unite in securing a permanent fire-proof building for their joint use. This is now being considered by a joint committee.

A committee was appointed to prepare a revision of the constitution and by-laws, with a view to rendering the organization better adapted to the needs of the electrical fraternity, and to increase the scope of its practical usefulness. The result of the labors of the committee will be laid before the Institute for approval at an early day.

On Wednesday May 20th at 10 a. m. a general meeting of the Institute convened for the reading of papers and their discussion by members present, Mr. Sidney F. Shelbourne occupying the chair. The first paper read was that of Mr. Frankland Jannus of Washington, on "The Protection of Electrical Inventions." Mr. Jannus pointed out the tendency of several recent decisions of the Supreme Court, in patent cases, and in view of the ground therein taken, strongly urged the importance of employing skilful and competent solicitors to prepare applications for patents, inasmuch as the examiner can only act on what is placed before him, and even if he sees that the applicant has omitted to claim the most important feature of the invention, it is no part of his duty to call attention to the omission. Formerly such omissions when discovered could be rectified by a reissue of the patent, but the Courts have now taken the ground that this cannot be legally done, except under very special circumstances. It is also necessary that the question of possible modifications be carefully considered, in order that the inventors rights be adequately protected.

An interesting discussion followed, during which members availed themselves of the opportunity to obtain correct information regarding patent-office methods and facilities, from the author of the paper, whose practical experience as a solicitor rendered his views of unusual value.

A paper on "The Cost of Mine Lighting" by F. P. Mills was read by the secretary. It was based upon the practical working of a Brush plant in a Michigan iron mine. Considerable difficulty had been experienced on account of the wires being broken by blasting, but so far as economy and efficiency was concerned the result was in every way satisfactory.

Mr. Edward P. Thompson read a paper on "The Electric Arc-Lamp Frictional Clutch." He attributed much of the irregularity of the arc-lamp to the faults of the ring-clutch now generally used. He then demonstrated by a model the working principle of a newly invented clutch, consisting of a spiral spring, through the coils of which the carbon-holder was permitted to slide with a gradual motion. The action was so perfect, as to elicit the applause of the audience. After a thorough discussion of the merits of the invention, a recess was announced, to permit the members and guests to partake of an elegant and substantial collation which awaited them in an adjoining room.

The afternoon session was resumed with Mr. Jannus in the chair.

Mr. E. P. Roberts, of Cheyenne, Wyoming, read a paper on "The Storage Battery in Commercial Use." This was of special interest for the reason that under the supervision of Mr. Roberts the secondary battery has been successfully adapted to incandescent lighting in Cheyenne to such an extent and for such a length of time that he feels entirely confident of its future. In giving the result of his two years' experience he expressed the opinion that storage batteries had been both praised and belittled too much; that the service could be made entirely satisfactory, but that he nevertheless preferred to employ the direct current from the dynamo wherever practicable. In reply to a question by Mr. Hamilton, Mr. Roberts stated that he believed about 75 per cent. of the energy expended was recovered, but had not made sufficient calculations to warrant him in giving such a result as authentic.

Mr. Frank L. Pope gave a brief summary of a paper by Prof. E. J. Houston on "The Delany System of Fac-simile Telegraphy," as owing to the lateness of the hour, it was deemed inexpedient to read it in full, and enter into a formal discussion of the subject. This closed the proceedings of the day. The meeting was an unusually successful and interesting one, and the discussions of the papers, which were participated in by many of the members present, elicited much miscellaneous information of value.

The papers read, together with the discussions which followed, will be published, and distributed to members, as each is revised and printed, instead of awaiting the completion of the entire work as heretofore.

THE AUTOMATIC SIGNAL TELEGRAPH CO. IN COURT.

Gen. Alexander Shaler was the president of the Automatic Signal Telegraph Co., and the owner of 291 of its shares, some of which were issued to him in payment for his services, a certain number being given him whenever a money dividend was declared to the stockholders. The Automatic Signal company having sold its property to its rival, the Watkins Automatic Signal Telegraph Co., for one-third of the capital stock of the latter, Gen. Shaler objected to the sale. He brought a suit in the Supreme Court to have it set aside, or for the alternative relief that 855 shares of the company of which he was president, remaining in its treasury, should be distributed to him and his fellow-stockholders, and that the shares of the Watkins company paid for the property purchased by it, should also be divided among the same persons proportionately to their several interests in the stock of the seller corporations. The two companies defended themselves on the ground that the sale was legal and that Gen. Shaler had no valid title to the stock of the Automatic Signal Telegraph Co. that was given him for his services.

The case was tried before Judge Andrews in Special Term, who rendered a decision to the effect that the sale of the property of the first-named corporation to the second named corporation was legal notwithstanding that a majority of the trustees of the one also formed a majority of the trustees of the other. Such a relation of the contracting parties one to the other, he says, does not of itself prove a fraud. He also holds that it was not necessary for the stockholders of the seller corporation to give their written consent to the sale at a meeting called for the express purpose of obtaining such writen consent, although that was decided to be the law in Reiff against the Western Union company. The decision in that case Judge Andrews says, was based on a printed copy of the statute in which a comma was misplaced. A certified copy of the original statute shows by its punctuation, in his opinion, that the legislative intent was that three-fifths of the stockholders of a corporation should approve of the sale of its property, either in writing, done anywhere, "or by vote at a general meeting duly called for the purpose."

Having thus disposed of Gen. Shaler's charge of fraud, Judge Andrews holds the defense, based on the ground that Gen. Shaler was not entitled to the shares issued to him by the Automatic Signal Telegraph Co. in compensation for his services, to be unsound. His conclusion is, therefore, that the Automatic Signal Telegraph Co. shall distribute among its stockholders its own stock held in its treasury, and also the Watkins Automatic stock received for the property sold by it.

REORGANIZATION OF THE POSTAL TELEGRAPH CO.

The scheme for the reorganization of the Postal Telegraph Co. may be accepted as an accomplished fact, the holders of over $9,000,000 worth of the bonds (out of a capitalization of $10,000,000) having signified their acquiesence in the plan prepared, which comprehends a capital in stock alone of $5,000,000, obtained as follows: $10,000,000 bonds at 35 per cent., $3,500,000; $10,500,000 stock at 5 per cent., $525,000; $700,000 cash at 105 per cent., $735,000; stock in treasury valued at $240,000; making a total of $5,000,000. It is claimed that this solution has been obtained chiefly through the efforts of Mr. John W. Mackay, who holds over $2,000,000 worth of the company's securities.

Judge Lawrence appointed A. B. Chandler and Henry Rosener temporary receivers of the Postal Telegraph and Cable Co., upon giving a bond in the sum of $75,000. The appointment of receivers was made by consent, in an action brought by Campbell C. Brown and Thomas Fleming against the company for the sequestration of its property. On the 15th ult. Messrs. Brown and Fleming recovered a judgment against the company by default for $105 368,45 upon a promissory note for $100,000 made in June, 1884, by the company to Mr. Henry Rosener, its second vice-president and general manager. The note was indorsed and assigned to Messrs. Brown and Fleming, but when payment was demanded it was not made.

THE "NOVELTIES" EXHIBITION.

The success of the electrical exhibition held last year at Philadelphia under the auspices of the Franklin Institute has led the Board of Managers to authorize the organization of an exhibition of novelties, to open on the 15th of September next, and to continue until Oct. 31. The exhibition buildings at 32d street and Lancaster avenue, will be utilized for this purpose. The exhibits will be restricted to such recent discoveries in the sciences, arts and manufactures as the committee may deem worthy of admission. The management has decided to return to the former custom of awarding medals and certificates as tokens of special merit. The nature of the exhibition indicates that there will doubtless be a considerable representation from the electrical field. Applications for space may now be made, and full information will be furnished by the Committee on Exhibitions, Franklin Institute, Philadelphia.

THE LONDON INTERNATIONAL INVENTIONS EXHIBITION.

Electric lighting continues to form one of the most important and interesting features of great exhibitions, owing, primarily, to the reason that satisfactory artificial illumination can be obtained only by its use. At the present exhibition, which opened May 6, various companies appear not only as exhibitors, but contractors for lighting the buildings and grounds. The Chinese lanterns and colored lamps, which have heretofore maintained their position for ornamental purposes, rather than illumination of walks and cosy bowers, have finally disappeared. The cornices and angles of the buildings are now delineated by rows of incandescent lamps, which are expected to develop sufficient light to fulfill the requirements of romantic ramblers. Such spaces as are not reached by the rays from the buildings which enclose the grounds will be supplied with small groups and rows of lamps, so that the entire out-of-door area will at least be relieved from darkness. This division of the lighting has been installed by Siemens Brothers, under the direction of Sir Francis Bolton. A special plant of three large dynamos, driven by a Matthews compound three-cylinder engine, has been placed for this purpose in the western arcade. The dynamos are of the upright compound type, capable of supplying about 6,000 five-candle lamps. The armatures of these dynamos are not wound with wire, the conductors being copper bars, which are now used in all excepting the smallest dynamos made by Siemens Brothers.

Those who have closely watched the development of electric lighting must have observed that recent progress has tended more generally in the direction of increasing the efficiency of apparatus by scientific construction, rather than in the invention of novel devices. This is the natural progress toward ultimate perfection, and is the result of experience in various fields and under various conditions. There are, consequently, but very few exhibits which can now be brought before the public possessing the popular merit of novelty. The Maxim-Weston, the Brush and the Edison-Swan systems are well known both in Europe and America. The Thomson-Houston system, however, now makes its first appearance in England, where it will doubtless receive considerable attention on account of its favorable reputation in America.

The Sun lamp, exhibited by the Sun Lamp and Power Co., of London, combines to a considerable extent the peculiarities of the arc and incandescent systems. The light is, in the main, derived from a block of marble, which the arc heats to a high degree of incandescence. Being of considerable size, it serves as a reservoir of heat for a sufficient time to overcome the fluctuations which are attendant upon the action of most arc-lamps. The marble is practically consumed in about 30 hours.

The Varley Flexible Carbon Lamp embraces some novel features consequent upon the peculiar formation of the electrode, which requires a different system of mechanism from the ordinary arc-lamp, the carbon being wound in long lengths upon bobbins. It consists of a wick or cord formed from a number of carbon filaments braided together. In this lamp the arc, rather than the heated points, is the source of light, and it more closely resembles a flame than is the case with any other pattern of electric lamp. This feature is of little importance in itself, but it is claimed by interested parties, and apparently on good grounds, that, by this system, arc-lamps of moderate powers may be run at a much less proportionate cost than heretofore. The tests made by the commission at the Paris electrical exhibition showed that the average spherical illumination from 90 Brush lamps was one candle per 1·17 watts of energy measured between the terminals of the lamps, also that the larger the lamp the greater its economy. The 20 Varley lamps at the present exhibition are each worked with a current of 2·5 ampères, and an electromotive force of about 45 volts. They emit a light which is estimated at 200 c. p., indicating a return of one candle per ·56 watt. Accurate photometrical observations have not yet been made, but even if reduced one-half, the result would be very satisfactory. The lamps at the exhibition are arranged five in series, and four in parallel, and consume 4½ in. of carbon per hour.

The flexible carbons are paid out by feed rollers, actuated by clockwork, and pass through tubular guides to the horizontal arc. Suitable mechanism is provided, by which the carbons may approach each other or recede, according to the condition of the arc, which has a tendency to curve itself upwards. This is prevented by a small refractory porcelain block, which serves as a reflector, and confines the flame within more moderate limits.

The Varley lamps are so arranged that each may be served by a current from a Gaulard & Gibbs secondary generator. The object of this system is to permit of the transmission of a large amount of electrical energy through a small conductor, from which it may be diverted at various points in such quantities and under such conditions as required. Thus it is practicable to derive from a small main currents suitable for large and small arc-lamps, Jablochkoff candles and incandescent lamps, requiring an electromotive force varying from five to 100 volts or more.

Wherever one or more lamps of the same character are located, a secondary generator is connected in the circuit, and a portion of the main current is thereby caused to induce nearly an equal amount of energy in a local secondary circuit. The apparatus by which this result is attained is based upon the principle of the Rhumkorff coil, being made up of two separate coils and an iron core. The coils are wound side by side on the core. The alternating current, passing through the first, induces a current in the second at each pulsation. There was originally considerable skepticism as to the practical value of this system, but the inventors have persevered in their efforts, and have been so far successful that they were last year awarded the grand prize of 10,000 francs at the Turin exhibition. Experiments made by Professor Ferraris and others show that 95 per cent. of the energy of the primary is converted into the secondary current.

The long-cherished idea of a successful rotary engine has been given renewed interest by the development of electric lighting; and among the new candidates of this class is the Parsons motor, for which the claim is made that it wiil run steadily many thousands of revolutions per minute without undue consumption of steam. So many ideas of this character have, however, disappointed their advocates, as well as the steam-using public, that it will be wise to await official tests before placing any faith in popular rumor.

ELECTRIC LIGHTING IN VIENNA.

The electric lighting installation which has been fitted up in the houses belonging to the Union Building Co., near the new Town Hall, serves for lighting up the rooms of the café and the restaurant on these premises, for the arcades, and also for a private house.

The machines and steam boilers for working the installation are in the sunk story of the house I., Ebendorfer strasse 6, and include:

Three boilers, with smoke-consuming furnaces, on the Ten Brink system, consisting of one steam collector, three upper boilers, six lower boilers, and one Ten Brink ante-boiler. They have a pressure of six atmospheres and a heating surface of 63 square metres each. One of these boilers is for the electric light, one serves in winter to heat the building by means of steam pipes, whilst the third is a reserve. The steam engine is a high-pressure horizontal, with Corliss gearing, the diameter of the cylinder is 370 millimetres, the stroke 790 millimetres, and making 69 revolutions per minute.

The dynamos are impelled by a countershaft, connected by the engine with a hemp driving-band.

For the glow lights there are used four Edison machines, each for 60 lamps of 16-candle power, or 120 at eight normal candles.

These machines supply 142 B lamps at eight normal candles, and 37 A lamps at 16 candles for the café, 188 B lamps for the restaurant, about 60 B lamps in a private residence, and 13 A lamps in the machine and boiler house, making together 490 B lamps, all the lamps being reduced to the B standard. The machines make 1,200 turns per minute. The glow lamps are all Edison's. For the six arc-lamps which light up the arcades, two Gramme machines are in use, one of which supplies two lamps at 1,000 normal candles, and the other four lamps at 1,000 normal candles.

The former makes about 850 turns, and the latter 1,300 turns per minute. The power expended for the normal working of the entire installation is 52 h. p.

The café has been lighted without interruption since May 15, 1883, and the restaurant since April 3, 1885. The steam boilers and engine were supplied by the firm of E. Skoda, of Pilsen. The entire installation has been carried out by Brückser, Ross & Co.

On April 17 the engineer, J. Kolbe, explained the arrangements in fullest detail to his pupils from the Technological Trade Museum. The installation has worked faultlessly from the very beginning.—*Zeitschrift für Elektrotechnik.*

AN IMPORTANT GROUP OF PATENTS.

There has been quite a general impression, that the field of invention in printing telegraph apparatus, had been so thoroughly reaped, that it offered but little encouragement for the inception and development of original ideas. That such is not the case, is practically proven by the issuance of 23 United States patents on April 28th, to Mr. Henry Van Hoevenbergh, of New York and Elizabeth, N. J., for printing instruments, and various devices identified with their practical working. These patents have all been assigned to the Baltimore and Ohio Telegraph Co., of which Mr. Van Hoevenbergh is the electrician. We believe that it is generally admitted that this gentleman has no peer in this line of electrical invention, to which he has devoted the most attention. Although the electric light and telephone have to a considerable extent monopolized recent popular notice, there are various other channels of usefulness for electricity, and those who have been identified with it, since the time when its only public mission was that of telegraphic communication, will be pleased to learn that its original dominion is not to become either depreciated through neglect, or stifled by the rank growth of modern improvements.

ELECTRIC GAS-LIGHTING CASE.

ELECTRIC GAS LIGHTING COMPANY *v.* SMITH & RHODES ELECTRIC COMPANY.

U. S. Circuit Court—Southern District of New York.

Decided March 16, 1885.

1. When a reissue is made between eight and nine years after the original, the specifications in the two patents being identical, it is not enough to support a new claim in the reissue that the inventor might have made the claim in the original patent; its subject-matter must have been claimed in some manner in the original or included within what was there claimed.

2. In this case the first claim in the original patent was for a circuit-breaker only, while the fifth claim of the reissue, which is sought to be founded on it, is for the machinery operating the circuit-breaker. As the claim in the original was not for a combination, the combination of the claim in the reissue cannot be said to be the same combination further restricted by additional elements. On reconsideration, it is *held* that the subject-matter of the reissue claim is not included in what was claimed in the original patent.

Mr. Edwin H. Brown for the orator.
Mr. Samuel B. Clarke for the defendant.

WHEELER, *J.:*
